"Slag bottom No. 5 boiler is a Springfield cross-drum boiler, having 21,620-sq. ft. heating surface, a water-cooled furnace surface of 2578 sq. ft., lined with refractory-faced block, and with Bailey walls on all four sides and on the ashpit slopes.

"The cooling surface as originally designed is divided as follows: side walls, 1247 sq. ft.; front wall, 726 sq. ft.; rear wall, 605 sq. ft., and hopper floors, 706 sq. ft., making a total effective cooling surface of 3284 sq. ft. The front and rear walls are covered with refractory-faced blocks. The side walls have all refractory-faced blocks, except the last four rows at the bottom which are bare cast-iron blocks. The two ashpit slopes are covered with bare cast-iron blocks. The furnace has a volume of approximately 18,000 cu. ft. and is fired with five Calumet intertube burners, designed to burn 8000 lb. of coal per hr. each at maximum. These burners are equally spaced across the front wall, the coal entering the furnace at an angle of 45 deg. to the horizontal. The air for combustion is preheated to about 370 deg. fahr. by a plate-type preheater.

"The ash removal system originally installed on No. 5 boiler required a great deal of labor and close attention for successful operation. The ash accumulated on the side walls and slopes at low ratings, and when the rating was raised on the boiler, this ash melted and avalanched down into the ashpit where, unless it was watched and dumped as fast as it came down, it blocked the ashpit gates or bridged over between the two ashpit slopes. When this happened it was necessary to break the slag out with bars and long pipes in order to get the gates and the opening between the front and rear slope clear again. To overcome these difficulties, a new bottom permitting the liquid removal of the slag was designed.

"The installation of this system required that the original bottom be changed somewhat. Four 21 in. I-beams are placed through the bottom parallel to the front and rear walls. On top of these and at right angles to them are placed eleven 9 in. I-beams equally spaced across the furnace from side wall to side wall. These 9 in. beams carry the ½ in. steel floor plate that completely covers the bottom. On top of this plate are two layers (5 in.) of standard fire brick and on top of the brick 9 in. of burned dolomite. A tap hole in the middle of the side wall is fitted with a cast-iron spout, which is closed by a gate operated with a wheel and worm gear. Suitable troughs, nozzles and breaker plates are provided to break up the slag and carry it to the ash sluiceway. About 35 tons of burned dolomite were put in the bottom and spread evenly over the fire brick and banked up against the sides and over the front and rear

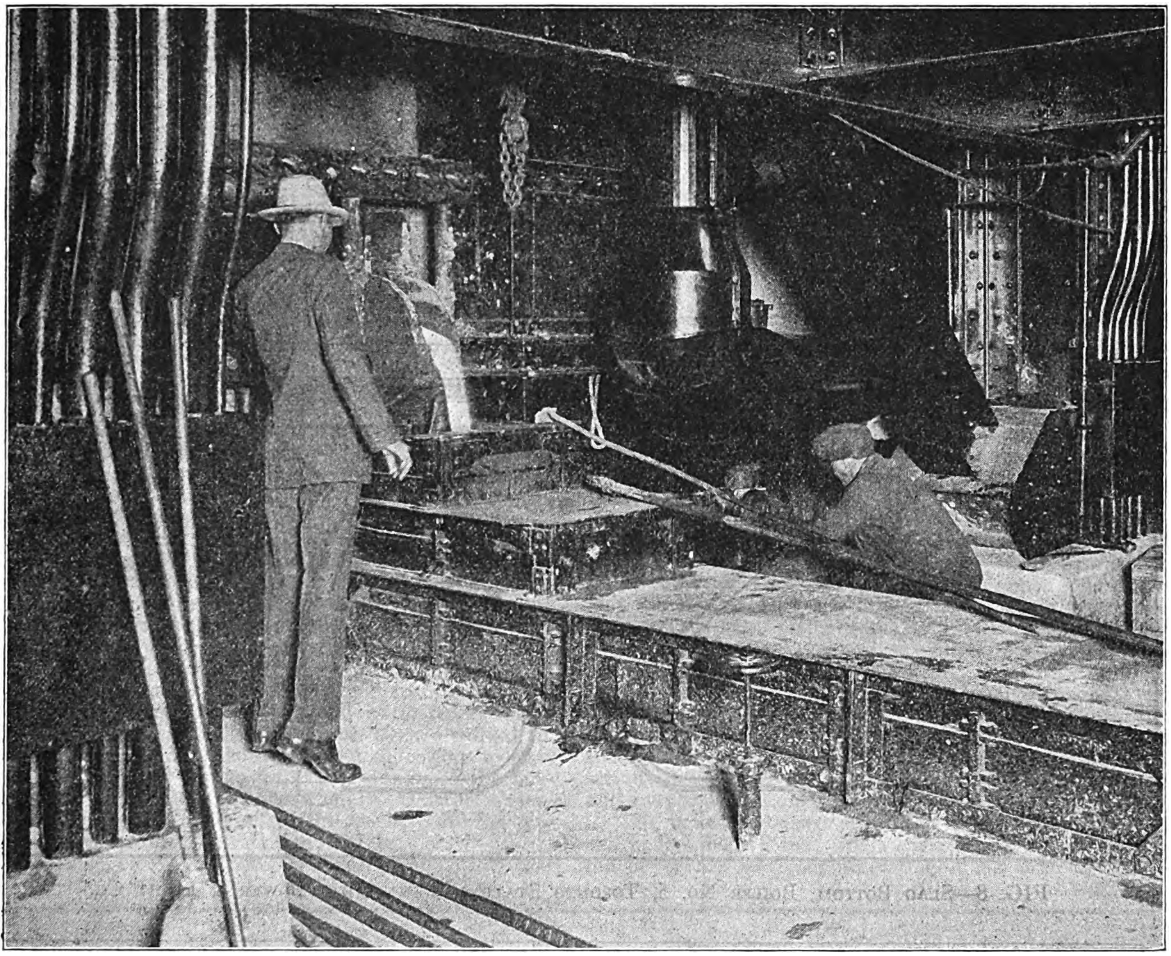

FIG. 7—SLAG SPOUT DISCHARGING MOLTEN ASH, BUFFALO GENERAL ELECTRIC CO.

wall intermediate header. Fig. 8 and 9 show the construction of the bottom and the manner in which the dolomite was banked up.

"This work was started March 14, 1928, and finished March 28, 1928. The furnace was not tapped the first day, and the boiler was operated straight through without banking. Slag was tapped the first time after 27 hr. operation and again 4 hr. later. It was then found that the dolomite which had been banked up against the front and rear intermediate headers had been washed off of these headers onto the bottom. The boiler was banked the night of March 30 to solidify the dolomite on the bottom.

"The tap hole is kept plugged with clay. In tapping, a bar is driven through this clay to the liquid slag. (An air-operated 'rivet buster' is now successfully used for this operation). The slag runs out through this hole down the cast-iron spout and falls into a spray of water, which breaks it up and carries it about 4 ft., where it strikes a breaker plate and falls into another stream of water moving at right angles to the first. This stream carries it about 4 ft., where it strikes another breaker plate and drops into the ash sluiceway. From here it is washed to the ash pump and pumped out to a fill. When the slag has been drained down to the proper level, the tap hole is plugged with clay and the flow stopped.

"Under normal operating conditions the slag is tapped once every 24 hr. The average run takes about 1½ hr. This varies, however, depending upon the boiler rating and the ash in the coal. No trouble has been encountered at any time in keeping the slag hot enough to run. The temperature of the slag leaving the spout varies from 2300 to 2700 deg. fahr. The temperature naturally affects the speed at which the slag runs, but at no time has it been low enough to retard the removal of the slag.

"The coal burned is bituminous and comes from several mines in Pennsylvania and from a strip mine near the plant. The percentage of ash varies from 10 to 15 per cent and the fusion point from 1900 to 2200 deg. fahr. As an experiment coal from eastern Pennsylvania containing 8 per cent ash and having a fusion point of 2900 deg. fahr. was burned in this furnace. This coal burned remarkably well, the slag liquefying and running as readily as that having a lower ash-fusion temperature, but it was thought probable that this was because this coal was somewhat mixed with other coal having a low ash fusion temperature, and another test was run on No. 4 boiler, which showed that Georges Greek Big Vein coal, having an ash-fusion temperature of about 2900 deg. fahr., could not be melted and tapped, and in order to remove the ash, it was necessary to fire coal having a low ash-fusion temperature so that the mixture of this ash with the ash already in the furnace formed a fluid which could be removed in molten form.

"Only two leaks have developed in the bottom since its installation: One between the south side wall and the bottom about halfway back, dripped for a few minutes and then froze; the other, between the north side wall and the bottom at the slag spout, was a larger leak, requiring the use of a water hose to stop it. Neither leak did any damage nor affected the operation of the boiler.

"The boiler has been in operation a little over six months with this type of bottom, and no unforeseen problems of operation or maintenance have arisen. The ash pit now needs attention only while being tapped, and when plugged can be forgotten until the next day. The slag comes to the

pump in a fine granular state resembling ground black glass, the largest grains being about the size of buckwheat. The slag washes and pumps easily, and a large amount of slag can be handled in a fraction of the time required under the old system."

Slag Bottom No. 4 Boiler

"Slag bottom No. 4 boiler is a B. & W. cross-drum boiler, with 20,470 sq. ft. heating surface and a water screen surface of 2100 sq. ft.

"The furnace as originally designed and constructed is of brick throughout. The side rear walls and bottom are protected by bare tube water screens. The center of these tubes is 6 in. from the walls and the tubes are spaced 10½ in. center to center. The side walls are of hollow wall-type construction, the secondary air passing through the walls from the rear to the wind box around the burners in the front. The furnace is 25 ft. high, 25 ft. long and 20 ft. 10 in. wide, and has a total volume of 13,000 cu. ft. The boiler is fired with six Toronto-type Peabody burners in two rows of three each, one above the other, which fire horizontally through the front wall. The same coal is burned as in No. 5 boiler. The air for combustion is preheated to about 300 deg. fahr. in a plate-type preheater.

"In operating the boiler as originally constructed, the ashes accumulated in a hopper at the bottom of the furnace, and from there were dropped into an ash sluice and washed to a pump from which they were pumped out to a fill near the plant. Difficulty was encountered with ashes and slag accumulating on the sides of the hopper and on the water-screen tubes. This was hard to get off and required a great deal of labor to keep the ash pits and water-screen tubes clean. Due to these difficulties and the labor involved, it was decided to experiment with a design of bottom to permit the liquid removal of the ash. The design of the bottom that was installed is shown in Fig. 10. This is a temporary installation and is sloped to follow the bottom water screen. The permanent installation will be flat.

"In changing No. 4 furnace, the rear wall below the water-screen tubes was cut out to permit the placing of I-beams to support the bottom. The bottom was built so that the tops of the 8 in. I-beams were above the tops of the water-screen tubes. On top of these beams was placed ½ in. steel plate, a layer of 2½ in. standard silocel brick, a layer of 2½ in. standard fire brick and 9 in. of burned dolomite banked up around the edges. The tap hole was placed at the end in the corner, about 5 ft. from the center of the bottom right-hand corner. A refractory lined spout was placed so as to discharge the slag into a steel trough. In this trough are the water jets into which the molten slag falls and is broken up and carried along the trough for about 9 ft. Here it strikes a breaker plate, drops into another trough and jets and is carried to the ash sluice. The sluice carries the granulated slag to the ash pump from which the slag is pumped to the fill.

"The boiler was fired up May 3 and was put on the line 8 hr. later. The boiler was tapped 8 hr. after this, and the slag ran for 55 min. It was tapped again after another 8 hr. and ran for 35 min. The temperature taken with an optical pyrometer during these runs was 2760 deg. fahr.

"After a day's run the slag broke through the bottom about 6 ft. out from the front wall, directly in front of the lower right-hand burner. The boiler was operated until it was convenient to take it off the line, when it was found that the silocel brick had broken down under the heat and exposed the steel plate to the slag. All the silocel brick were removed and standard fire brick put in their place, making two layers of fire brick and 9 in. of dolomite on the furnace bottom. These repairs required about a day's time. A number of times, due to the temporary construction of the bottom, the slag leaked through the openings around the water screen tubes. None of the leaks were serious or caused any outage. The permanent installation will overcome this difficulty.

"The boiler is tapped once each 24 hr., the average slag run being about 2 hr.; this varies, depending on how long the boiler has been on, the rating it has been operated at,

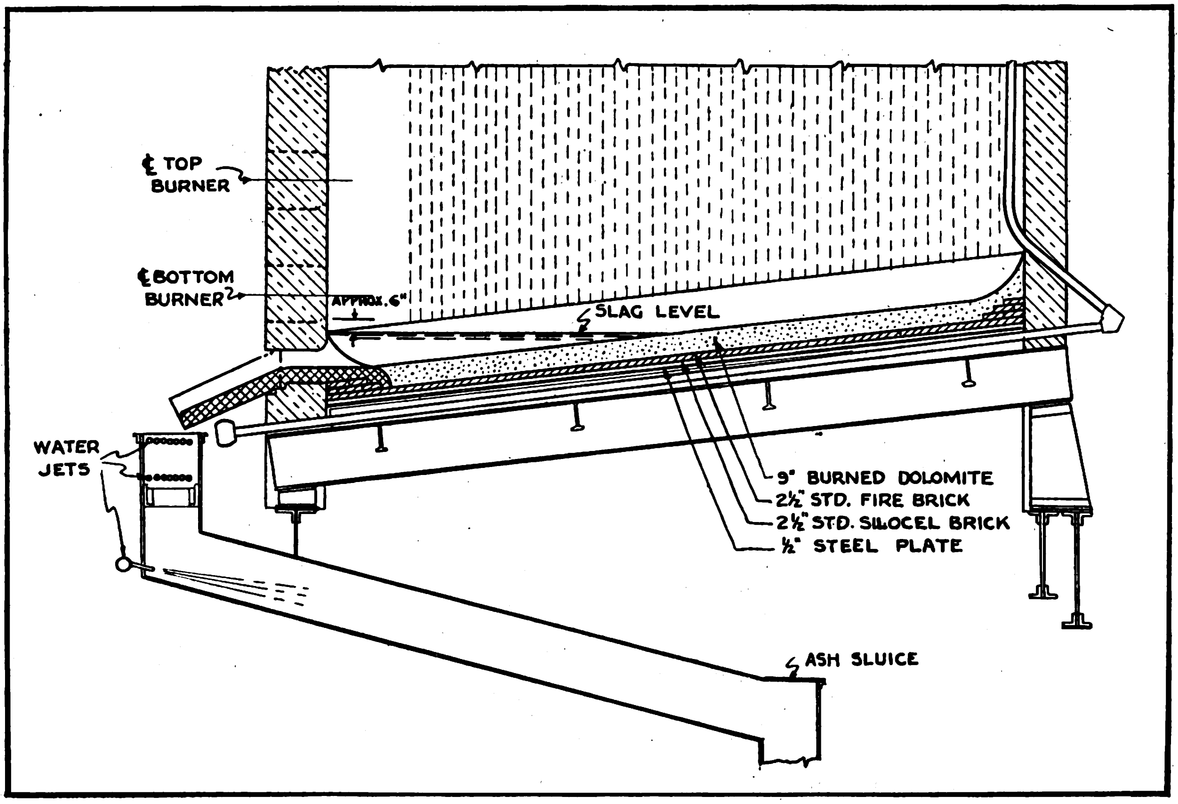

FIG. 10—Slag Bottom, Boiler No. 4, Toronto Station, Penn-Ohio Power & Light Co.

and the ash in the coal. Up to this time there has been no erosion of the brick work around the slag line.

"Approximately 30 tons of dolomite were used in the bottom when it was put in, and about 20 tons have been used since that time for repairs.

"There has been no change in the method of starting up the boiler. The same method is used with the slag bottom as was used before its installation."

STATEMENT BY THE OHIO PUBLIC SERVICE CO.

Development of the Non-Segregating Coal Distributors

"To obtain homogeneity and equal distribution, so necessary for good combustion efficiency, the natural tendency of coal to segregate into its various sizes while feeding into the stoker hopper must be checked. The problem of coal segregation has received a great deal of thought from plant operators throughout the country, and a number of devices for eliminating this trouble have been tried, with varying success. All of these devices have motors or other moving parts which require attention and are subject to wear and breakage. They require power to operate, and quite a number of them fail, at times, under certain conditions, to accomplish their objective. In addition to these disadvantages, they are quite expensive, so that the carrying charges on them make a material cut into the savings effected by them.

"The reason these spreaders fail to perform the purpose for which they were intended is easily seen. They miss the fundamental of the problem viz., the cause of segregation. All of the spreaders allow segregation to take place at will and then undertake to re-mix the coal and get it mixed in uniform proportions across the width of the stoker hopper. While considering this problem at the Lorain Plant, an idea was hit upon to prevent the start of segregation.

"Coal sliding down an inclined plane behaves in the same way as when poured into a pile. The small sizes work their way straight down the dip of the planes and crowd the larger pieces aside. When the coal reaches the hopper, after sliding down a fantail chute, most of the dust and slack is in the middle, while the nut size is nearly all collected in two clearly defined, narrow strips at the ends of the hopper. A chute was designed in which there is no steepest path. Instead of a plane surface, a conical surface was used as the sliding plane of the chute, on which all paths of descent have the same slope.

"To test the principle just explained, two model chutes were built, one being a replica of those in use at the time, having a plane as the sliding surface; the other patterned after the new design, using the outside of the cone as the sliding surface. These models were built to one-quarter size and provided with hoppers, at the top, for filling. The hoppers were filled with a representative mixture of coal, and the chutes were dragged backward over the floor, allowing the coal to discharge at the bottom of the chute in a manner similar to the way the stoker rams would push out the coal from the large chutes in actual practice. The swath of coal thus discharged was divided into eight parallel strips, which represented the discharge from eight sections of the width of the chute. These divided quantities were then passed through screens and the relative proportions by weight of the various sizes computed.

"The results of a series of parallel tests of the two chutes were plotted on coordinates and are shown in Fig. 11. Three screens were used, 2-mesh, 4-mesh and 8-mesh per in. The percentage, by weight, of the four sizes obtained were plotted as ordinates, and the width of the chute was used as the abscissa. The average proportion of each size in the total mixture is shown by the dotted line, and the figures are given below the curves for each test. The results are plotted in cumulative fashion to throw the curves apart. If perfect distribution obtained, the points which represent the characteristics of the chute would coincide with the dotted lines, indicating that the mixture contained its average proportion of all sizes at all points. Departures from these lines measure the degree of segregation. It will be noted that in all the tests the performance of the conical chute approached very nearly to the perfect line, the maximum deviation being only about 5 per cent, while the test of the straight chute showed several variations as high as 25 per cent in adjacent sections.

"The first shovelful of coal put into the straight chute went directly down the middle, whereas the first coal put into the conical chute was distributed equally across the entire width. When the hopper was emptied during a test, and the chute dragged back until all coal was discharged, it was noticed that the coal left off along a sort of parabolic curve from the straight chute, but left off evenly along a straight line from the conical chute. When burning out a hopper full of coal before shutting down a boiler, it has always been necessary to run the stoker a long time to get rid of the coal over the middle rams, or else get a long-handled shovel and distribute it over the other rams. With the conical chute we are assured that all rams will be coaled equally by the first coal that comes down, and that, if it be necessary to burn out the hopper to stop smoking, or for any other reason, that the hopper will be emptied at all parts at about the same time.

"At all times during the test extreme care was exercised in making the test conditions the same for both chutes. In dividing the coal for sizing and weighing, the ends of the piles are discarded in order to base the figures on only that coal which would be discharged during continuous operation. A further advantage would accrue to the conical spout if the starting and stopping coal had been included.

"The design of the conical chute is as follows:

"The surface on which the coal slides (the bottom of the chute) is a cone whose apex is at the spout under the weigh scales and whose base circle lies in the horizontal plane through the top edge of the stoker hopper, and passes through the front end corners of the hopper. The chute was designed to fit the present hoppers and weigh scale spouts, and, therefore, it will be readily seen the altitude and base radius of the cone, and consequently the slope of its surface, were arbitrarily fixed by our boiler-room layout. Since the dimensions of the hopper were not such as to permit the use of a complete circular base arc, the cone was cut off at the lower end, as can be seen in Fig. 12, by a vertical plane passing through the front edge of the stoker hopper. A number of partitions were placed in this lower section to stiffen the structure and prevent segregation after the coal had passed over this knee on its travel vertically downward into the hopper.

"The results of the test being highly satisfactory, two full-sized chutes were built and put into actual use.

Conical Spouts in Service

"The conical chute was installed on one boiler, fired by an underfeed stoker, sixteen retorts wide. At the very outset it was apparent that the chutes were successful. The fuel bed was even all the way across the furnace, and for the first time there were no holes under the side observation doors. The depth over the ash pit was uniform, and when the clinker grinders were operated the level was depressed evenly clear across the width. This latter characteristic was new and hitherto unknown to the operators.

"Since these chutes were put into operation, the plant coal rate has been materially reduced, and while all of this gain cannot be attributed to these chutes it is believed that very appreciable gain in economies has been effected by them. Comparison of ashpit analyses shows a decided improvement in combustible losses in favor of the boiler equipped with the conical chute. The firemen report that it is much easier to keep the Bailey meter hands together on this boiler than on the others, since they have better control of the excess air. It was also found unnecessary to manipulate the sectional dampers across the width of the stoker, as the even fuel bed permitted the use of a steady air pressure across the stoker. This made possible a greater steaming capacity on this boiler, since no part of the stoker need be held in check.

"Flue gas analyses, taken from time to time, show that there is much less stratification of gases in this unit, and the carbon dioxide recorder also shows that the average

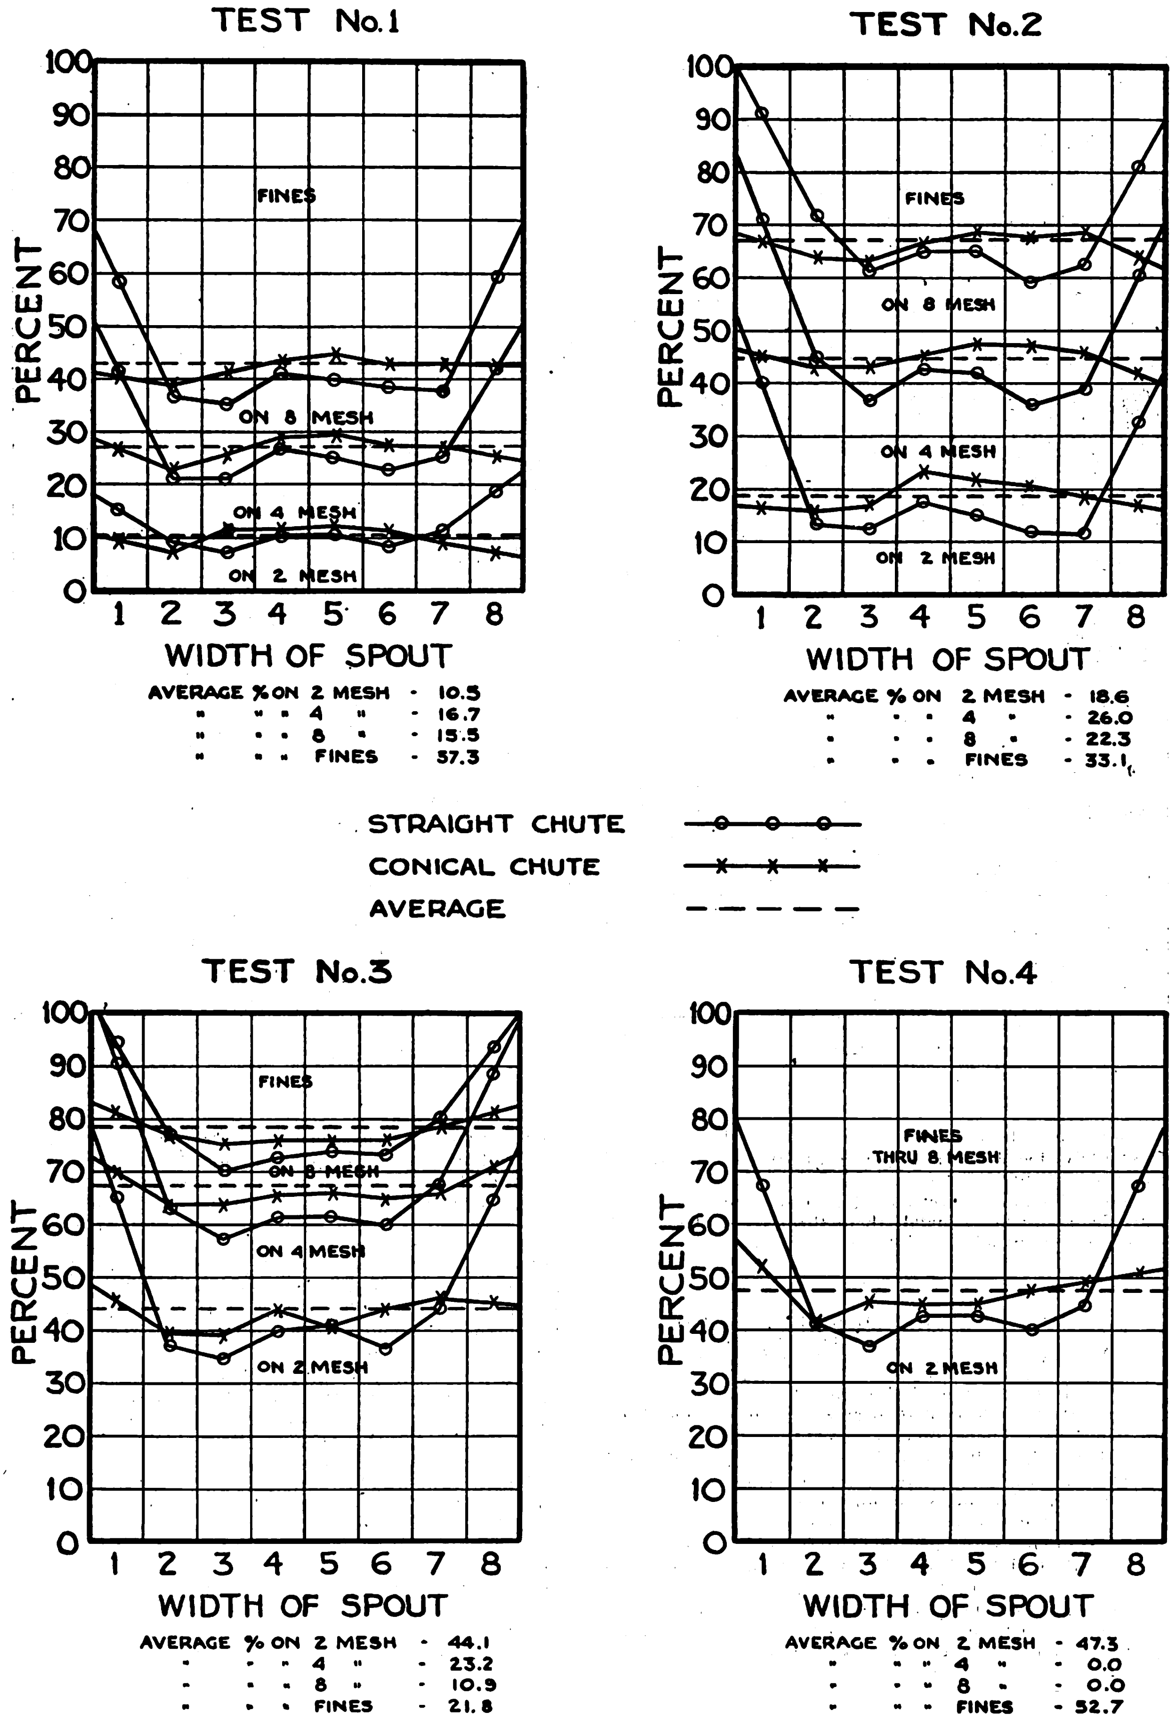

FIG. 11—RESULTS OF TESTS ON SPOUTS, SHOWING DEGREE OF COAL SEGREGATION, OHIO PUBLIC SERVICE CO.

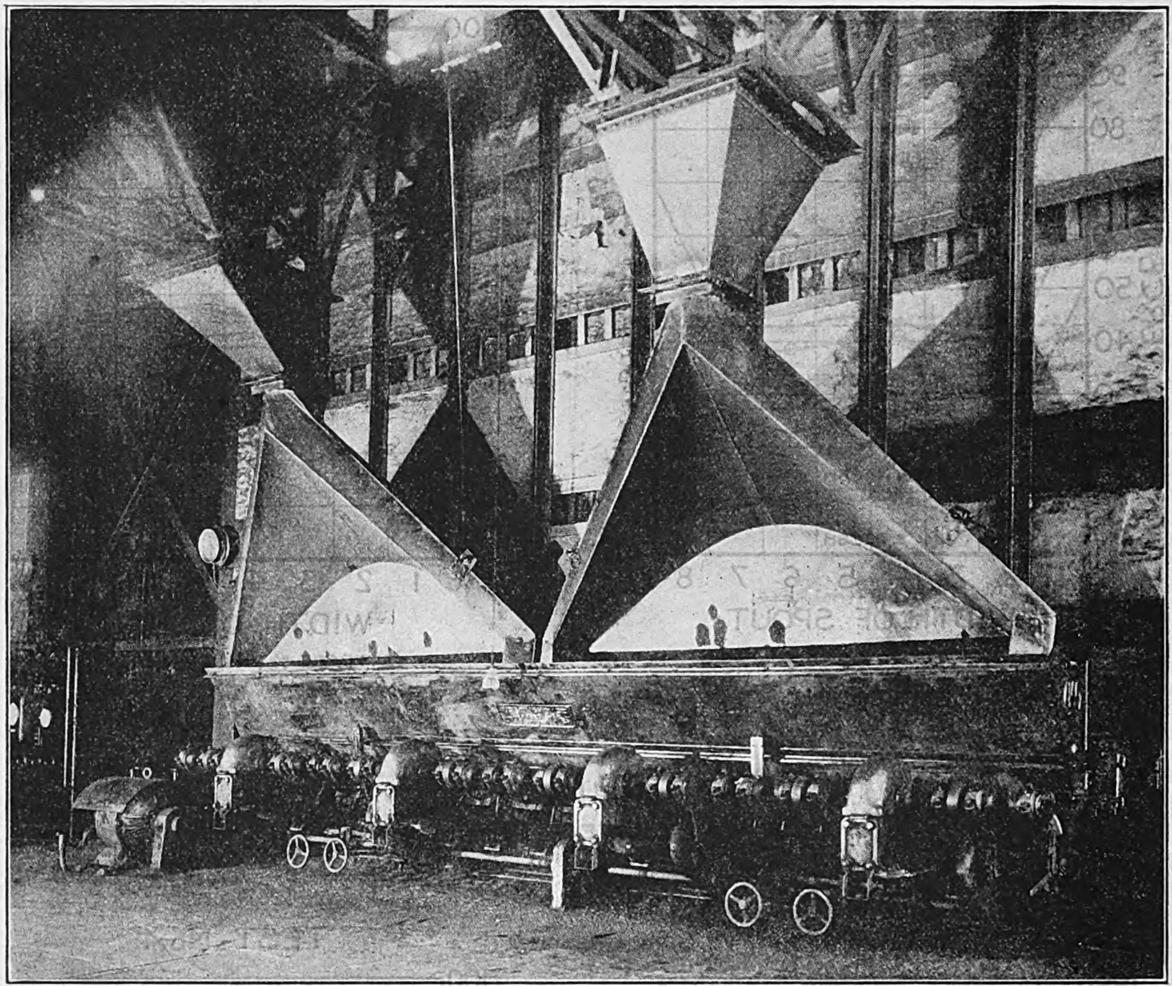

FIG. 12—COAL DISTRIBUTOR IN SERVICE, OHIO PUBLIC SERVICE CO.

CO_2 content has been decidedly improved, the variation being scarcely more than 2 per cent over a period of nine hours.

"The conical chute is considered entirely successful, and plans are being made to install them throughout the plant."

STATEMENT BY THE OHIO EDISON CO.

Non-Segregating Coal Distributors

"There are in use at the Mad River Plant at Springfield, Ohio, four of the Rolland Gardner Co. non-segregating coal distributors. These served two 14 retort, 29 tuyere Taylor stokers. The coal used is an eastern Kentucky and West Virginia bituminous, having an ash content of about 9.3 per cent with 3.6 per cent moisture.

"The distributors have been in use about ten months. Ordinarily 2 in. nut and slack coal is used, but some mine run is burned, which, of course, goes through a crusher before going to the bunkers. The coal burned will run, on the average, approximately 50 per cent coarse, 30 per cent medium and 20 per cent fine. The coarse coal is of such size that it would all pass through a 2 in. screen. Considerable coal has also been reclaimed from storage, and this coal contained about 10 per cent moisture. Even this quality of coal flows freely down the spouts and through the non-segregating distributors, without any tendency to clog. At no time has there been any clogging of coal in the spouts or distributors.

"One of the benefits derived from the use of these chutes is that the fuel bed is kept in an even condition, the coarse and fine coal being fed into the stoker hopper thoroughly mixed, there being no tendency toward segregation. There is no doubt that increased furnace efficiency results from an even and well distributed fuel bed, but no tests have been made at our plant to determine the increase. On the B. & W. boilers of the type used in our station the only brickwork used is in the front wall, and thus far there has been no maintenance on this wall.

"The distributors are made of ¼ in. steel plate, with riveted and welded joints, and no extreme wear has been found on them. With coals of higher ash content or with a more abrasive action, the distributor linings would probably show more wear.

"We believe this type of distributor serves as an excellent means of getting fuel to the stokers, and that it is a decided improvement over the ordinary spout in that it is a non-segregating affair and has no moving parts."

MANUFACTURERS' STATEMENTS

STATEMENT BY SAUERMAN BROTHERS, INC.

Description of Power Drag Scraper System

"The drag scraper system described here was designed to solve the problem of placing two kinds of coal in separate piles in one storage area; either coal to be delivered on either side of the area and all coal reclaimed at one point. The storage area, approximately 1000 ft. long by 400 ft. wide, was laid out with a slip on one side and rail tracks on the other, so that either cargo boats from the lake or cars could be unloaded. The problem, therefore, was unusual in that two grades of coal would be received either by water or by rail. The stocking out machinery had to be suitable for stocking these in separate piles in the same storage area. All of the coal had to be reclaimed at one common point, a receiving hopper which fed a belt conveyor. The coal received by water came in two kinds of boats, one the self-unloader type, the other of the type which requires a dock crane for unloading. Either of these types created a long, high pile of coal when the boat was unloaded. The coal received by rail came in the usual manner through an overhead chute which deposited the coal on an initial pile. The unusual features of this problem, therefore, can be set down as follows: 1—Coal entering the storage area on two opposite sides; 2—two grades of coal which had to be kept separate in the storage area; 3—the unusual height and length of the 'initial pile' created at the point where the boats were unloaded; 4—large capacity required at long hauls on account of size of storage area. The problem was solved by the installation of a 7 cu. yd. Sauerman Power Drag Scraper Storage System.

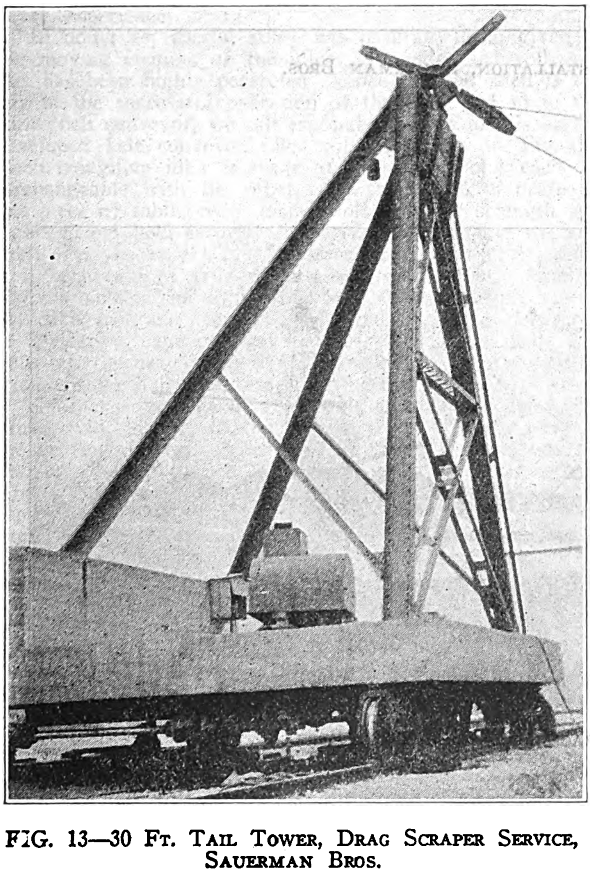

FIG. 13—30 FT. TAIL TOWER, DRAG SCRAPER SERVICE, SAUERMAN BROS.

"It was decided to put a track around three sides of the storage area on which two tail towers, Fig. 13, of the scraper system could operate. This track was so arranged that on the water side of the area it could also serve as the track for the dock crane that unloads the boats which are not self-unloaders. These towers are an unusual feature of the installation because of their exceptional height, 30 ft. from top of rail to bearing of sheave block, made necessary because of the high initial pile. Both of these high tail towers are self-propelling.

"The reclaiming hopper with the head post was located on the rail side of the storage area, about halfway from each end. The scraper was installed with an operating cable of the endless type, that is, the cable was threaded through the sheaves on the tail towers, then through the fairlead blocks on the head post, and then to the hoist drums, where one end of the cable was attached to the rear drum of the hoist and the other end of the cable to the front drum. Attachments were provided so that the cable could be connected to the scraper bucket at any point. Both drums of the hoist have the same rope speed and line pull so that the loaded scraper can be operated from either drum. The result of this is an operating cable in the form of a triangle, one point being the head post, the other two points being the movable tail towers. The scraper can be operated in either direction on any side of the triangle. The movable tail towers, which operate at a speed of 100 ft. per min., can quickly be located at any desired point on the track and the scraper then placed in operation in whatever manner the exigencies of the situation require. This is made possible, of course, only because two points of the triangle (the tail towers) are movable.

"A total storage capacity of 100,000 tons is provided for in this installation. While the reclaiming belt conveyor is designed for a handling capacity of 150 tons per hour, the scraper equipment is actually capable of handling about 200 tons per hour across the width of the area. The length of scraper haul varies considerably, the electric hoist operating under load for a longer period of time on the long hauls than on the short hauls, and for this reason the power consumption per ton of material handled will vary from ½ to ¾ kw., depending upon the length of the haul.

"The general layout of the storage area is shown in Fig. 14, while Fig. 15 shows the cargo boat slip, the unloading crane, one of the movable tail towers and the position of the high initial pile of coal unloaded from boats.

"In addition to the height of the tail towers, the use of two movable towers in one scraper installation is quite unusual. The equipment was put in operation late in the spring of 1928 and is operating in a very satisfactory manner, the large capacity requirements being met in the manner anticipated."

STATEMENT BY THE LINK-BELT COMPANY

Improved Conveyor Belt Idler

"Handling large quantities of material at low cost is work to which the belt conveyor is admirably suited. Its large capacity, due to its continuous delivery of material at a relatively high speed, its low upkeep and its small power consumption make for a minimum handling cost per ton.

"To take the utmost advantage of the possibilities that the belt conveyor offers, four things are required: 1—Low coefficient of friction of its moving parts with its attendant decreased power consumption; 2—long belt life; 3—low rate of depreciation, and 4—small maintenance cost. Depreciation and maintenance can be kept down by the use of high-grade equipment. The other essentials to economical service, belt protection and low power consumption are largely controlled by the character of the idlers.

which constitute the road bed on which the belt travels. The service given by the conveyor depends, therefore, upon the construction of the idlers, and it is upon this that the Link-Belt Company has focused particular attention, building into Link-Belt idlers the results of years of belt conveyor experience.

"In doing so, special study has naturally been given to the moving element of the idlers, the individual roll, and this has been highly perfected. Since the roll shell is the key to the successful operation of the idler and so to the entire belt conveyor, we call especial attention to this highly developed belt conveyor idler roll as shown in Fig. 16. Each troughing idler is made of three unit rolls, each interchangeable with the other. The roll shell is made of one piece of tubing with dished roll ends for strength and rigidity, and held securely in position by spinning the roll shell over the ends. This construction gives a shell which is light in weight, true running and with smooth, rounded edges which cannot injure the belt. The roll ends are of malleable iron and are part of the end castings which serve as a bearing cage and grease reservoir. Both shells and hubs are accurately bored and turned to secure concentricity of the hub with respect to the roll shell.

"Another advantageous feature is an adequate supply of grease which is contained in the reservoir on both sides of the bearing, so that gravitation will supply grease to the bearing whether the roll be in an inclined or level position. The grease seal of the roller bearings is of the labyrinth type, contained in a cap or housing, making it a unit in itself, and protected by a deflector plate, both of which very effectively prevent any foreign matter getting into the bearing.

"The design is such as to permit the removal of the rolls without the use of tools. The brackets supporting the rolls are securely riveted to the tee iron frame which acts as a self-cleaning base and prevents the collection of material which would cause the roll to become a brake wheel rather than an idler roll.

"The Link-Belt Company through years of experiment and tests recommend and furnish idler rolls fitted with shells, made of material having the greatest wear value and such that will best resist the bearing action imposed upon them, whether it be abrasion or corrosion or a combination of both."

STATEMENT BY THE AMERICAN PULVERIZER COMPANY

Ring Coal Crusher

"The American Ring Coal Crusher, used for preparing coal, coke or lignite for automatic stokers or as a breaker ahead of pulverizers, is different from other crushers in that it employs manganese steel rings as a crushing medium. Because of its unique design, this crusher offers the following characteristics and advantages: Simplicity in construction and operation; exceptional ability for passing tramp iron without damage, due to the flexibility of the rolling ring system; low power consumption per ton of crushed material; unusually low maintenance cost, because of manganese grinding parts, and capability of producing various size products, due to the adjustable grinding plates.

"Fig. 17 shows one of the types of American Ring Crushers, with the upper housing removed. The crusher proper is mounted on a heavy cast iron base, extended at one end to provide a mounting for the driving motor. The lower half of the crusher case consists of heavy steel cast-

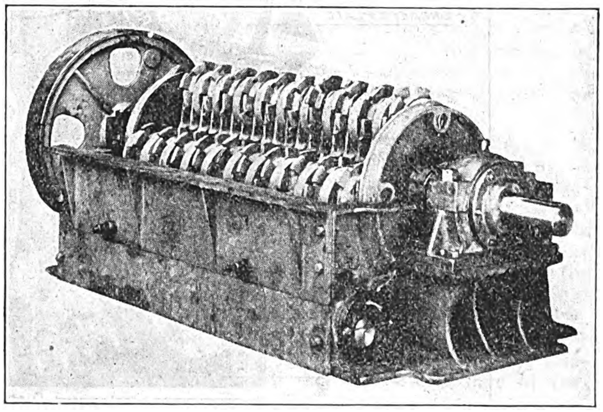

FIG. 17—AMERICAN RING CRUSHER, AMERICAN PULVERIZER CO.

ings, bolted to the base, and having the bearing pedestals cast integral with the end frames. The upper half of the case, which includes the hopper, consists of a number of heavy sections bolted together in such a way that practically any of them are removable to permit inspection of the interior. The lower half of the case is provided with a removable plate on the back side for convenience in taking out accumulations of tramp iron.

"The rings are mounted on a carbon steel shaft extending the length of the crusher, and, in reality, consist of a number of loosely mounted smooth and shredder rings. When the machine is in operation the rings are thrown out by centrifugal force, so as to crush the material against the adjustable crushing plates. If a ring strikes a refractory object, such as a piece of tramp iron, for example, it simply rebounds, and is not in any danger of being broken. This flexibility of the rolling ring system protects the machine from foreign material, such as fish plates, coupling pins, mine props and even mine car wheels. A grizzly screen is provided that serves two purposes: it deflects tramp iron to the receptacle in the bottom of the case and prevents any uncrushed or heavy lump material dropping through the machine with the crushed coal delivered. Fig. 18 is a cross section of the machine, showing plainly the breaker plate and adjustable grinding plate, both of manganese steel, the manganese steel rolling rings of both the plain and shredder type and the grate bars, as well as the lower rear access door.

"The crusher is directly driven, through a flexible coupling, by a motor mounted on the same base plate. The shaft is supported at two points by Timken tapered roller bearings, mounted in removable housings bolted to the bearing pedestals. Each mounting includes two bearings mounted indirectly on the shaft, the method of mounting being such that the assembly on the motor end is fixed, while that on the other end is permitted to float. The whole arrangement is such that perfect shaft alignment is permanently maintained, provision being made for shaft expansion. A heavy flywheel is mounted on the shaft opposite the driven end, which smooths out the operating load peaks, and thus serves to remove some of the strains on the driving motor. Because of the roller bearings, the machine, in starting, comes up to speed very quickly and without undue effort on the part of the motor, or disturbances on the line. The power factor of the motor is also improved because it is not necessary to overpower the machine.

"In Fig. 17 the eccentric adjustment for the adjustable grinding plate can be seen in the lower right-hand end of the housing. These machines are also built of cast iron construction, using, however, the same principle and the manganese steel wearing parts. The units in service have proved entirely satisfactory and the service is dependable."

STATEMENT BY THE R. H. BEAUMONT COMPANY

Skip Hoist Standardization and Ash Hoppers

"Skip hoists in the past have grown more or less promiscuously, a new design being made when and if existing designs proved inadequate, or if some new problem arose. During the past year, however, the R. H. Beaumont Company has brought out a complete new series of skip hoists. Investigations were started by plotting a curve of lifts and capacities of all skips ever built by this company, as well as all those that were bid on, to find out just what a skip hoist series was. After months of investigation there was established a relationship between size of bucket, size of winding machine and motor, cable lift and cable speed and tons per hour. Towers and guides were made more rigidly standard and in many respects interchangeable; the number of bucket sizes and types was reduced, and tee rail guides, instead of being bolted or attached to gusset plates within the towers, are now attached with cast steel yokes, only three sizes being used for the entire range of skip hoists. Many engineers will argue that steel castings are not necessary for attaching guides to a tower because there is not sufficient shock to cause a break normally in cast iron, but this company felt that the annoyance of replacing such a chair or yoke in a tower was sufficiently great to justify the additional expense of steel castings, and by simplification and standardization, the steel castings can be produced cheaply enough to warrant their use under almost all conditions.

"Winding machines are now all roller bearing, there being only four sizes of winders to cover the entire range of capacities. Only two sizes of roller bearings occur in each winder. Sheaves are all roller bearing with standard supporting beams, permitting the use of the same beams in

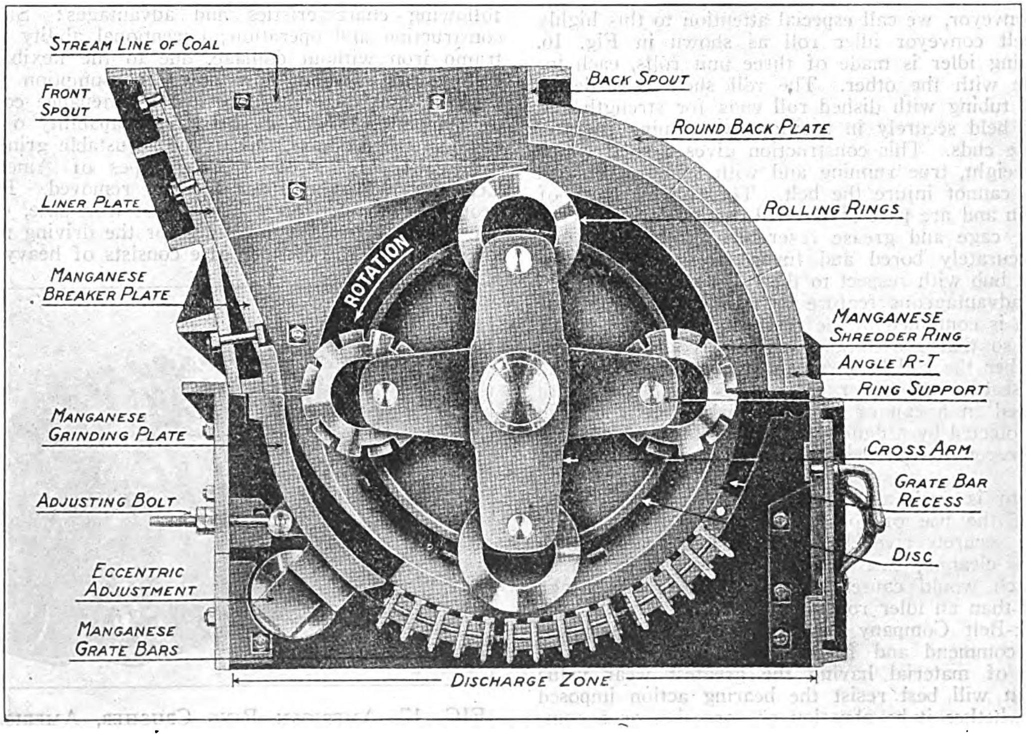

FIG. 18—CROSS SECTION OF RING CRUSHER, AMERICAN PULVERIZER CO.

any type of cable layout. The patented simplex loader has been completely redesigned, making it more rigidly aligned and smoother in operation. Many more detailed improvements, simplifications and standardizations have been accomplished which are too numerous to mention here.

Electrically Operated Ash Gates

"In the field of ash-handling equipment the Beaumont Mfg. Company, a subsidiary of the R. H. Beaumont Company, has accomplished several very interesting things, notably among these being the development of electrically operated ash gates. This application is now fully covered by United States letters patent on both the spur gear operated units and on the screw type of operation. All installations made so far are of the spur gear type, but it is thought that the screw type will be the one most commonly used in the near future, as it can readily be adapted to replacing existing operating cylinders in other types of gate operation. The spur gear type of electric drive for ash gates is shown in Fig. 19.

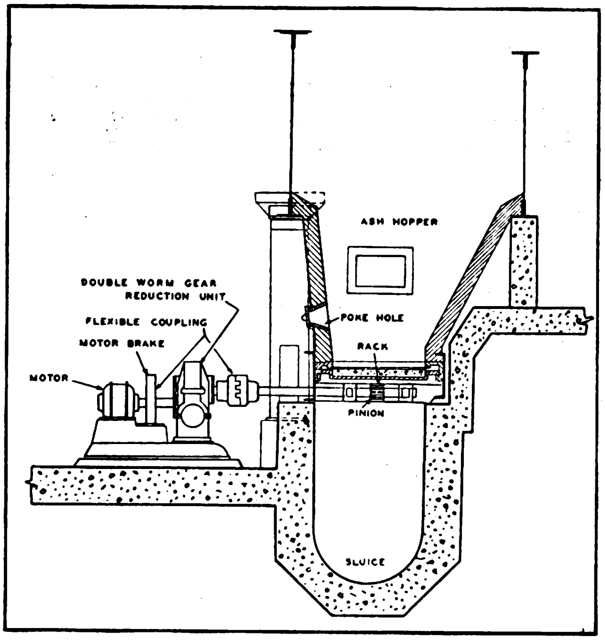

FIG. 19—MOTOR OPERATED ASH GATE, R. H. BEAUMONT Co.

Vestibule Ash Hopper

"Another development of this company is the so-called vestibule ash hopper for pulverized fuel installations, which is a system for quenching pulverized fuel and ash prior to disposal and without interfering with the boiler operation. The object is, of course, to handle the ashes by a car and skip hoist system, thereby eliminating not only the expensive sluicing system, but the many nasty problems attendant on the use of a sluice.

This vestibule system, shown in Fig. 20, consists of a copper-steel furnace bottom very similar to the ash furnace bottom used in pulverized fuel systems. The bottom opening of this furnace floor is fitted with horizontal, air-tight, slide gates, either hand or power operated, usually power. Below these gates is attached our standard gravity, copper-steel, discharge ash hoppers which are lined with vitrified shale brick and equipped with spray quenchers, poke holes, drained pivoted gates, etc. With such a system, ashes can be discharged from the furnace into the quenching hopper, and after the upper gates are closed any action which goes on within the quenching hopper is not transmitted to the furnace."

STATEMENT BY THE ROLLAND GARDNER COMPANY

Non-Segregating Coal Distributor

"Elimination of coal segregation has come to be one of the paramount problems in boiler room design and operation. High CO$_2$ and efficient combustion depend primarily upon the intimate mixture of air and coal in the correct ratio. This ratio of total air to total coal may be accurately controlled, but this does not mean that all parts of the fuel bed receive their proper quantities of air. If part of the fuel bed consists of coarse coal and part of fine, the air will follow the path of least resistance, that is, through the coarse coal. This part of the fuel bed will burn out faster, lowering its resistance, and hence further increasing the excess air. On the other hand, the fines will receive less than the proper amount of air and will burn slowly and incompletely, resulting in liberation of CO, stratification of gases and excessive combustible in the ash. Proper air distribution, uniform combustion, uniformly high CO$_2$ and low combustible can be maintained only if the fuel bed has coarse and fine evenly distributed.

"The purpose of the non-segregating coal distributor, manufactured under the trade name of 'Non-Seg,' is to prevent this segregation and to deliver to the stoker hopper coal which is uniformly mixed across the entire width of the stoker. This coal distributor is the outgrowth of extensive tests and a thorough study of the causes and effects of coal segregation and offers the following advantages: 1—Uniform fuel bed; 2—Even combustion across stoker; 3—Less stratification of gases; 4—Higher average CO$_2$; 5—Increased boiler rating; 6—Higher combined boiler and furnace efficiency; 7—Lower stoker and furnace maintenance, and 8—Less attention to fire.

"The 'Non-Seg' coal distributor is based upon a very simple theory that is most effective in practice. The bottom plate of the distributor is a section of a cone having a vertical axis, hence the slope is the same down all elements of the cone. If coal is delivered at the apex, it slides down all elements in equal quantity without any tendency to roll sidewise or segregate. Each particle of coal, regardless of size or condition, follows its straight line element, and the coal is uniformly distributed across the stoker hopper. There are no moving parts and consequently no upkeep. The spout is effective, and its design is such that it can easily be installed in all plants distributing coal from overhead bunkers or by larries running at suitable height. One or more distributors may be used for a given boiler width, depending upon height available or the number of openings desired from overhead storage. In construction the plates of the spout are electrically welded throughout, thus eliminating siftings and drips.

"Down spouts to non-segregating coal distributors may be vertical or they may slope toward the boiler, but they should not incline laterally at an appreciable angle unless suitable means are provided to correct segregation in the down spout itself, for the fines naturally sift to the lower side of the spout. This condition may be corrected by inserting a spiral feeder, manufactured by this company, at the entrance of the distributor to change the position of the coarse and fines and permit of proper entry into the distributor.

"Inasmuch as a distributor has to be built up so as to have passage through which the coal may travel without congestion, there is a slight difference between the theoretical distributor consisting of a single conical surface and the actual chute consisting of that volume inclosed between two conical surfaces. A slight amount of sifting can take place with this latter design, but it is not parallel to the stoker front but rather perpendicular to it. This slight segregation causes no ill effect in operation of stoker and, to a great extent, the coal is remixed before it reaches the stoker itself. Further analysis of the design of the non-segregating spout reveals the fact that the volume of coal between an increment of width at the center of the distributor outlet and the apex is the same as the volume of coal between an equal increment of width at the end of the distributor outlet and the apex. This means that when the

distributor is emptied it will empty straight across rather than running out at the ends first and in the center last. This feature is a decided advantage whenever it is desired to empty the stoker hopper.

"Losses and difficulties due to coal segregation are prevalent and the non-segregating coal distributor eliminates them simply and completely."

SPECIFICATIONS

The purpose of the Specifications Subcommittee's work is to formulate general specifications for the major items of power plant equipment. The aim is to assist the specification writer in producing specifications which will clearly describe the equipment wanted and the performance expected of it under given conditions.

It is recognized that inflexible standards cannot be set up to apply in all cases. Therefore, no attempt has been made to place any limits on the characteristics of the equipment. It is assumed that the specification writer is sufficiently familiar with the equipment wanted to determine the necessary details, and to place the limits to meet his own particular conditions. It is hoped that with these forms before him, he will be able to produce a specification which will cover in the present report material on several related sub- with a minimum of effort.

The previous reports covered a general outline and standard forms for specifications for boilers, boiler feed pumps, surface condensers, underfeed stokers, forced draft fans, superheaters, economizers, chain grate stokers, induced draft fans, turbo-generators, evaporators, piping, pulverized fuel equipment and coal handling equipment. The present report covers a general outline and standard forms for specifications for air preheaters, closed heaters and deaerating equipment. These forms are intended to be used primarily as a checking list and as an outline of a form to be used. It is not expected that all items are necessarily included or that all of the items covered in the form will be required in each case, and spaces have been left where specific items should be filled in by the specification writer. All paragraphs not needed should be omitted. To make the forms clear, certain figures and statements have been inclosed in parentheses to indicate that these items are to be changed to suit conditions.

In addition to the usual general outline and standard forms for specifications for power plant equipment, this Subcommittee has, upon request, included in the present report material on several related subjects of particular interest to the specification writer or purchaser. This additional matter includes a form for analysis of proposals, an index of generally accepted standards and lists of reports of investigations.

PURPOSE OF SPECIFICATIONS

The purpose of specifications is to set forth in as brief and concise a manner as possible the requirements of the purchaser and to state the information which the purchaser desires the bidder to submit in order that the proposals may be properly considered and compared.

To obtain the best results, the specifications must describe clearly what is wanted, but should restrict the manufacturer only in so far as is necessary to obtain the desired quality and capacity. Being too explicit regarding the manner in which the purchaser's requirements shall be met often requires specially designed equipment at a higher price than would be asked for a standard type which would satisfactorily meet the real requirements.

The information requested of bidders should be of such a nature, and in such detail, as to make possible a complete and impartial analysis and comparison of the quality and performance of the material or equipment quoted on. Only information necessary to such selection should be requested; any other information desired can best be obtained later from the successful bidder.

A complete contract for a major item of power plant equipment will usually consist of:

A. Formal Agreement.
B. General Conditions of the Contract.
C. Specification.
D. Instructions to Bidders.
E. Manufacturer's Specifications.
F. Drawings.

A. The Agreement is the formal and legal part of the contract and usually sets forth the legal name and address of the contracting parties, the price and terms of payment, that previous communications conflicting with the contract shall be null and void, etc.

B. The General Conditions of the contract should cover such items as:

1. Definitions of Terms Used.
2. Engineer's Status.
3. Inspection and Supervision.
4. Damages.
5. Changes in Work.
6. Insurance, Fire, Public Liability, Workmen's Compensation, etc.
7. Ownership or Acceptance.
8. Permits.
9. Liens.
10. No Waiver Clause.
11. Patent Rights.
12. Sub-Contracts.
13. Other Work Coincident with Work in Question.
14. Removal of Debris.
15. Prosecution of Work in Harmony with Other Contractors.

Publication No. 289-49, Serial Report, Prime Movers Committee.

16. Interpretation of Drawings and Specifications.
17. Control of Labor Forces.
18. Arbitration.
19. Statement of Completion.
20. Termination of Contract.
21. Any Other Items Desired by Purchaser.

C. The Specification proper should include only requirements which can be definitely stated, but no items which properly belong in the Agreement, the General Conditions of the contract, or in the Instruction to Bidders. The Specification should include:

HEADING, PLACE AND DATE

1. Scope.
2. Service.
3. Operating Conditions.
4. Description of Apparatus.
5. Description of Appurtenances.
6. Materials.
7. Drawings.
8. Guarantee.
9. Test.
10. Insurance.

D. Instructions to Bidders should supplement the Specification proper, including any additional items of information necessary for intelligently submitting a bid.

Items to be included are:

1. General:
   - (a) State when and where proposals are due, whether in duplicate or otherwise, and whether they should be signed by an authorized member of the firm submitting the bid.
   - (b) State where plans and specifications may be seen.
   - (c) Right to reject bids.
   - (d) Contract.
2. Form of Proposal:
   - (a) State whether bidders shall quote lump sum price, or otherwise.
   - (b) Preliminary drawings.
3. Facilities:
   - (a) Railroad.
   - (b) Siding.
   - (c) Water.
   - (d) Electric Power.
   - (e) Compressed Air.
   - (f) Crane.
   - (g) Storeroom for Materials.
   - (h) Office.
   - (i) Shanties, Scaffolding and False Work.
4. Shipping Instructions.
5. Unloading:
   - (a) State who will unload.
   - (b) State who shall be responsible for material unloaded.
6. Labor Conditions.
7. Terms of Payment.
8. Information accompanying proposal.

E. Manufacturer's Specifications should include in detail type of equipment, size or capacity, guaranteed performance, dimensions and weights, construction, materials, erection, and facilities for repairs, renewals, or cleaning.

F. The Drawings, if necessary, should accompany the Specification and form a part thereof.

AIR PREHEATER(S)

Instructions to Bidders

For Air Preheater(s) for Power House at
(Philadelphia, Pa.)
(A.B.C. Power Company)
Specification No. (.......)

(Philadelphia, Pa.)
(Date)

General

1. (Duplicate) proposals will be received at the office of (the Purchasing Agent of the A. B. C. Power Co. at Philadelphia, Pa.) up to (5 p.m., Nov. ....) for the work outlined in the inclosed specification.

2. Bid price shall be submitted on a sheet separate from all other data.

3. Bidders shall visit the site and familiarize themselves with every phase of the work before submitting proposals.

4. All drawings and specifications furnished with requests for bids shall remain the property of the (Purchaser), and shall be returned with the proposals.

5. The right is reserved to reject any or all bids.

6. The successful bidder shall enter into a written contract with the Purchaser for the performance of the work included in the specifications.

7. This contract will be drawn up by the (Purchaser) and will include (Purchaser's) and (Contractor's) Specifications, Instructions to Bidders and the "General Conditions" of the contract, copy of which is attached hereto. In case of conflict between (Purchaser's) and (Contractor's) specifications, the (Purchaser's) specification shall rule.

8. BOND: The successful bidder shall (....) be required to furnish a written bond, for the full amount of the contract price, to the Purchaser. The cost of this bond will be paid by the Purchaser.

9. FORM OF PROPOSAL: Bidders are requested to state a (lump sum price) for furnishing, (and delivering and erecting) the equipment specified.

10. Each proposal shall be accompanied by drawings giving general dimensions, and drawings or cuts showing in detail the construction of the equipment offered.

11. DELIVERY: Delivery (and completion of erection) desired (....).

12. FACILITIES:
- (a) The plant is located on the (B. & O.) Railroad (with a siding entering the plant).
- (b) Water will (....) be furnished (free) by the Purchaser.
- (c) Power will (....) be furnished (free) by the Purchaser.
- (d) Power available is (220) volts (a-c.) (60 cycles) (3 phase).
- (e) Compressed air (at 100 lb.) will (....) be furnished (free) by the Purchaser.
- (f) Crane of (....) ton capacity is available. Crane operator will (....) be furnished (free) by the Purchaser.
- (g) Storage space will be available (inside the plant), or remote storage alongside the tracks of the (B. & O. Railroad) with-(out) store houses approximately (....) miles from the plant.
- (h) Office space (with telephone, light and heat) will (....) be furnished (free) by the Purchaser.
- (i) (Contractor) shall supply tool and work shanties, scaffolding and falsework.

13. SHIPPING: Purchaser will furnish shipping instructions.

14. UNLOADING: The (Purchaser) will unload materials delivered by the Contractor and (advance) (freight) (and carting charges). The (Contractor) shall assume all responsibility for care and protection of the same after unloading.

15. LABOR CONDITIONS: (Union) (Non-union) labor.

16. TERMS OF PAYMENT:
- (....) per cent on receipt of (bill of lading) for (complete) shipment.
- (....) per cent on completion of (....) per cent of erection.
- (....) per cent on completion of erection.
- (....) per cent (....) days after acceptance by the (Engineers).

Information

17. The following information shall be given with each proposal and will be made a part of the contract entered into with the successful bidder:
- (a) Sq. ft. of active heating surface in contact with (flue gas) (air) in (each) preheater.
- (b) Dimensions, gage, shape, material, number and arrangement of heating elements in (each) preheater.
- (c) Dimensions of space occupied by (each) preheater.
- (d) Number and arrangement of passes for gas and air in (each) preheater.
- (e) Method of and space required for removing and replacing heating elements.
- (f) Complete description of equipment provided for removal of soot from gas passages.
- (g) Description of preheater supports.
- (h) Details of casing(s), details and location of inlet and outlet connections and method of attaching heat insulation.
- (i) Facilities provided for inspecting and cleaning preheater(s).
- (j) Details of design and construction of rotor(s), supports, bearings and guides, if required.
- (k) Number, type and details of design, construction and operation of fans, if included.
- (l) Details of design, construction and operation of driving mechanism(s), if required.
- (m) Rating and speed of motor(s) (included) (required), and speed of rotor(s), if used.
- (n) Description of tools and accessories included.
- (o) Complete manufacturer's specifications of the equipment.
- (p) Guaranteed performance of (each) (number) preheater(s), under conditions of boiler operation as stated in accompanying specification, with boiler(s) served by preheater(s) operating at (100, 200, 300 and 400) per cent of rating.
    - 1—Draft loss through flue gas side of preheater(s), in. of water.
    - 2—Draft loss through air side of preheater(s), in. of water.
    - 3—Temperature of flue gas leaving preheater(s), deg. fahr.
    - 4—Temperature rise of air, deg. fahr.
    - 5—Temperature of air leaving preheater(s), deg. fahr.
    - 6—Rate of leakage between air and gas elements, lb. per hr.
    - 7—Heat recovered by preheater(s), B.t.u. per hr.
- (q) Power required to operate (each) preheater, if any.
- (r) Power required to operate fans, if included.
- (s) Weight of (each) preheater, including casing, and motor and fans, if included.
- (t) Weight and size of largest piece.
- (u) Shipping point.
- (v) Date of shipment (and time necessary to complete erection).
- (w) Per diem charge for services of Contractor's erector or representative not covered by the contract.
- (x) Any other details wanted by Purchaser.

Specification

For Air Preheater(s) for Power House at (Philadelphia, Pa.)

(A.B.C. Power Company)

Specification No. (......)

(Philadelphia, Pa.)
(Date)

Scope

1. This specification covers the furnishing, (and delivery and erection) of (number) air preheater(s)

for the (new) (present) power plant of the (A. B. C. Power Co.) located at (Philadelphia, Pa.). The preheater(s) shall be furnished (and installed) with all appurtenances directly a part thereof and necessary to place (them) in successful operation, with the exception of such appurtenances as may be herein otherwise provided for.

[NOTE: This specification applies only to the usual types of air preheaters which utilize waste heat in the boiler flue gas. Under certain conditions it may be more feasible to use a preheater which employs steam or hot water as the heating medium.]

Service

2. The preheater(s) will be installed in connection with (number) (type) boiler(s) (and number) (type) (economizers) as shown on drawing(s) (numbers and titles) attached hereto.

3. ALTERNATE: The preheater(s) will be installed in connection with (number) boiler(s) (and number) (economizers) as follows:

(a) Type of boiler, (horizontal) (water tube).
(b) Arrangement of boiler tubes, (number high and number wide).
(c) Width of (each) boiler setting, inside, (....) ft.
(d) Boiler(s) set (in battery).
(e) (Number) pass, (reversed) setting(s).
(f) Size and location of boiler flue opening(s), (....).
(g) Type of economizer(s).
(h) (Arrangement of economizer tubes).
(i) (Width of each economizer setting, inside, ... ft.).
(j) (Size and location of economizer gas outlets).
(k) (Each economizer will serve .... boilers).

4. HEATING SURFACE: The following heating surface will be provided ahead of (each) (number) preheater(s):

(a) (....) sq. ft. of boiler heating surface.
(b) (....) sq. ft. projected area of water-cooled wall surface.
(c) (....) sq. ft. of (type) superheater surface.
(d) (....) sq. ft. of economizer surface.

5. OPERATING PRESSURE: Boiler(s) will be operated at (....) lb. per sq. in. gage steam pressure. (Economizers will be operated at .... lb. per sq. in. gage pressure).

6. FUEL BURNING EQUIPMENT: (Each) boiler will be provided with (type and size) (stoker).

7. DRAFT EQUIPMENT: (Number) (type and size) forced draft and (number) (type and size) induced draft fans will be provided. (State also number of each per boiler).

8. ALTERNATE-DRAFT EQUIPMENT FURNISHED BY CONTRACTOR: Forced and induced draft fans, integral with the preheater(s), shall be furnished (and installed) by the Contractor. Fans shall be of ample capacity, of suitable design and shall maintain the following static pressures when boiler(s) served by the fans (is) evaporating (....) lb. of water per hour under specified conditions of operation:

(a) Forced draft fan(s), (....) in. of water.
(b) Induced draft fan(s), (....) in. of water.

9. OPERATING CONDITIONS: The preheater design shall be governed by the following operating conditions:

(a) The boiler(s) will be operated at a normal load of (....) per cent and a maximum load of (....) per cent of manufacturer's rated capacity, with performance data for (each) (number) boiler(s) as follows:

Boiler load % of rating	(100)	(200)	(300)	(400)
Water evaporated, lb. per hr......	(35,000)	(70,000)	(105,000)	(140,000)
Flue gas to preheater(s), lb. per hr.	(.....)	(.....)	(......)	(......)
Total combustion air, lb. per hr..	(.....)	(.....)	(......)	(......)
Air to preheater(s), % of total	(.....)	(.....)	(......)	(......)
Air to preheater(s), lb. per hr.	(.....)	(.....)	(......)	(......)
Temp. of flue gas to preheater(s), °F.	(.....)	(.....)	(......)	(......)
Temp. of air to preheater(s), °F.	(.....)	(.....)	(......)	(......)

(b) The fuel to be burned is (bituminous coal) (from .... field) having (....) per cent sulphur and (....) per cent moisture, as fired.

Description

10. DESIGN AND CONSTRUCTION: (Each) preheater shall be designed and constructed

(a) to withstand safely and without distortion a continuous maximum flue gas temperature of (800) deg. fahr., forced draft pressure of (+10) in. of water and induced draft pressure of (−10) in. of water.
(b) gas and air tight so that there will be not more than (0.5) per cent CO_2 loss in gas passages from inlet to outlet under any conditions of operation.
(c) with proper provision for expansion and contraction.

11. TYPE: The preheater(s) shall be of the (stationary) (rotating) (plate) (tubular) (unit) (sectional) type.

12. ARRANGEMENT: There shall be (number) preheater(s) for (each) (number) boiler(s). The preheater(s) will be located (....), to receive gas from (economizers), deliver gas to (induced draft fans), receive air from (forced draft fans) and deliver air to (boiler furnaces). The maximum space to be occupied by (each) preheater shall not exceed (....).

13. GAS FLOW: The flue gas flow shall be (upward) and (counter) (parallel) to the air flow.

14. CAPACITY: Sufficient heating surface shall be provided in (each) (number) preheater(s) to give an increase in air temperature of not less than (....) deg. fahr. when boiler(s) served by the preheater(s) (is) evaporating (....) lb. of water per hr. under specified conditions of operation.

15. SOOT REMOVAL EQUIPMENT: Suitable and adequate means for the removal (and collection) of soot from the gas passages of the preheater(s), (while in operation), shall be furnished (and installed) by the (Contractor). (Steam at a pressure of .... lb. per sq. in. gage and a total temperature of .... deg. fahr will be available. All flanged outlets to which Purchaser's piping connects shall be steel faced, drilled and constructed in accordance with the A.S.A. American Standard for this pressure and temperature, with bolt holes spot faced on back).

16. SUPPORTS: All preheater (and motor) supports, including structural steel other than beams and columns forming part of the building structure, shall be furnished (and installed) by the (Contractor).

17. STEEL CASING(S): Preheater casing(s) constructed of steel plate not less than (3/16) in. thick and suitably reinforced shall be furnished (and installed) by the Contractor. Where possible all joints in casing(s) subject to gas or air leakage shall be (welded). Where necessary for erecting or dismantling, joints shall be bolted and provided with suitable gaskets. Adequate provision shall be made for the attachment of heat insulating covering, which will be furnished (and installed) by the (Purchaser).

18. INLET AND OUTLET CONNECTIONS: The flue gas and air inlets and outlets of (each) preheater shall be arranged for suitable and convenient connection to ducts or other equipment. Connection(s) between preheater(s) and (boilers) (economizers) (forced draft fans) (induced draft fans) shall be made by the (Contractor). (Purchaser to give details of connections to be made by Contractor).

19. ACCESSIBILITY: All parts of the preheater(s) shall be provided with a sufficient number of air or gas tight (cast iron) doors, manholes and hand holes to make the interior readily accessible for inspection, repair or for the removal of internal parts or foreign matter.

20. DRIVE(S): A complete driving mechanism for (each) preheater, if of the rotating type, shall be furnished (and installed) by the Contractor. A (Manufacturer) (variable) speed (slip ring) (a-c.) motor of suitable capacity, for (....) volts, (.... phase), (.... cycles) shall be provided for (each) preheater. Motor(s) shall be capable of continuous operation at full speed and load with a temperature rise not exceeding (40) deg. cent. above an ambient temperature of (40) deg. cent. and shall be provided with proper starting and control equipment (with overload and under voltage protection). If preheater(s) (is) provided with integral fans, motor(s) shall have sufficient capacity to properly drive both preheater(s) and fans connected with (it). All rotating parts of preheater(s) shall be designed and constructed to withstand a starting torque equal to (300) per cent of normal full load torque.

21. ALTERNATE—MOTOR(S) FURNISHED BY PURCHASER: Motor(s) and control equipment specified herein will be furnished (and installed) by the Purchaser. (The Contractor shall send the half couplings for the motor shafts to the motor manufacturer, express prepaid, to be mounted on the drive shafts. The other half couplings shall be mounted on the driven shafts).

22. TOOLS: The Contractor shall furnish one complete set of special tools and wrenches necessary for the operation and maintenance of the equipment.

23. MATERIAL: All parts of the equipment coming in contact with steam at a temperature above (450) deg. fahr. shall be of (steel, monel or ....). All steel plate work coming in contact with flue gas shall be (....). All tubes shall be (....).

24. MATERIAL BY PURCHASER: The Purchaser will furnish and install the following:

(a) Preheater (and motor) foundation(s) (and supports), foundation bolts, washers and grouting.
(b) Ducts and connections, including dampers, between preheater(s) and other equipment (except as otherwise specified).
(c) (Insulating covering).
(d) (Soot removal equipment).
(e) Piping, if required.
(f) (Forced and induced draft fans).
(g) (Motors).
(h) Electric wiring (and install only, switches and controllers), if required.
(i) Field paint.

25. PAINTING: Preheater casing(s) shall be given one shop coat of (....) heat resisting paint and all structural iron and steel work one shop coat of (red lead) paint before shipment. (All finished parts shall be slushed over before shipment and cleaned by the Contractor after erection is completed).

26. ERECTION: The (Contractor) shall be responsible for the erection and preliminary operation of the equipment covered by this specification under the general direction of the (Engineers).

Drawings

27. (Two) copies of certified drawings shall be submitted to the (Purchaser or his) Engineers for approval within (....) calendar days after contract is placed. The (Purchaser or his) Engineers will examine these certified drawings only for gen-

eral design, general dimensions and apparent suitability, and will approve them or return them for changes desired. Such approval will not relieve the Contractor of responsibility to furnish equipment which will perform successfully under the specified conditions. After drawings are approved (four) copies shall be furnished (as soon as possible). After installation is completed (two) more copies of corrected drawings shall be furnished.

28. (Two) copies of sectional views and lists of parts with piece numbers shown thereon shall be furnished the Purchaser to facilitate the ordering of repair parts.

29. (Two) copies of any special operating instructions shall be furnished to the (Engineers) when preheater(s) (are) shipped.

Guarantee

30. The Contractor guarantees that the apparatus to be furnished will be free from all defects in design, workmanship and material, and will give successful service under the conditions required and specified. The Contractor agrees to replace f.o.b. (....), without expense to the purchaser, any part of the apparatus which may prove defective within (....) year(s) after apparatus is placed in operation.

[NOTE: Purchaser may wish to insert here, or in the formal contract, a requirement for a broader guarantee, calling for the Contractor to be responsible for furnishing equipment which will perform successfully under the specified conditions and to make good, without cost to the Purchaser, any defects of whatever kind, even including removal of the entire equipment and replacement thereof by similar or differently designed apparatus, which will perform in successful manner.]

Tests

31. Purchaser's Inspector shall have free access to the equipment during the process of its manufacture and construction.

32. If the Purchaser so desires, an acceptance test shall be run on (one of) the air preheater(s) at the expense of the Purchaser and under the rules of the latest A.S.M.E. Test Code (....). This test shall be made within (180) days after the preheater(s) (is) placed in service. The Contractor will be given an opportunity to have a representative present to see that the preheater(s) (is) operated properly, and he will be given every opportunity to take observations or to apply any instruments desired, unless a different arrangement is made by mutual agreement. Should this test indicate that the equipment does not meet all guarantees included in the contract, the Contractor shall, at his own expense, make such other tests as may be necessary to show that the contract has been fulfilled.

[NOTE: It may be desirable under certain special conditions to add at this point a bonus and penalty clause or liquidated damages clause.]

CLOSED HEATER(S)

Instructions to Bidders

For Closed Heater(s) for Power House at
(Philadelphia, Pa.)
(A.B.C. Power Company)
Specification No. (......)

(Philadelphia, Pa.)
(Date)

General

1. (Duplicate proposals will be received at the office of (the Purchasing Agent of the A. B. C. Power Co. at Philadelphia, Pa.) up to (5 p.m., Nov. ....) for the work outlined in the inclosed specification.

2. Bid price shall be submitted on a sheet separate from all other data.

3. Bidders shall visit the site and familiarize themselves with every phase of the work before submitting proposals.

4. All drawings and specifications furnished with requests for bids shall remain the property of the (Purchaser), and shall be returned with the proposals.

5. The right is reserved to reject any or all bids.

6. The successful bidder shall enter into a written contract with the Purchaser for the performance of the work included in the specifications.

7. This contract will be drawn up by the (Purchaser) and will include (Purchaser's) and (Contractor's) Specifications, Instructions to Bidders and the "General Conditions" of the contract, copy of which is attached hereto. In case of conflict between (Purchaser's) and (Contractor's) specifications, the (Purchaser's) specification shall rule.

8. BOND: The successful bidder shall (....) be required to furnish a written bond, for the full amount of the contract price, to the Purchaser. The cost of this bond will be paid by the Purchaser.

9. FORM OF PROPOSAL: Bidders are requested to state a (lump sum price) for furnishing, (and delivering and erecting) the equipment specified.

10. Each proposal shall be accompanied by drawings giving general dimensions, and drawings or cuts showing in detail the construction of the equipment offered.

11. DELIVERY: Delivery (and completion of erection) desired (....).

12. FACILITIES:
   (a) The plant is located on the (B. & O.) Railroad (with a siding entering the plant).
   (b) Water will (....) be furnished (free) by the Purchaser.
   (c) Power will (....) be furnished (free) by the Purchaser.
   (d) Power available is (220) volts (a-c.) (60 cycles) (3 phase).
   (e) Compressed air (at 100 lb.) will (....) be furnished (free) by the Purchaser.

(f) Crane of (....) ton capacity is available. Crane operator will (....) be furnished (free) by the Purchaser.
(g) Storage space will be available (inside the plant), or remote storage alongside the tracks of the (B. & O. Railroad) with-(out) store houses approximately (....) miles from the plant.
(h) Office space (with telephone, light and heat) will (....) be furnished (free) by the Purchaser.
(i) (Contractor) shall supply tool and work shanties, scaffolding and falsework.

13. SHIPPING: Purchaser will furnish shipping instructions.

14. UNLOADING: The (Purchaser) will unload materials delivered by the Contractor and (advance) (freight) (and carting charges). The (Contractor) shall assume all responsibility for care and protection of the same after unloading.

15. LABOR CONDITIONS: (Union) (Non-union) labor.

16. TERMS OF PAYMENT:

(....) per cent on receipt of (bill of lading) for (complete) shipment.
(....) per cent on completion of (....) per cent of erection.
(....) Per cent on completion of erection.
(....) per cent (....) days after acceptance by the (Engineers).

Information

17. The following information shall be given with each proposal and will be made a part of the contract entered into with the successful bidder:

(a) Sq. ft. of active heating surface in (each) heater.
(b) Number, length and arrangement of tubes in (each) heater. (Name of manufacturer and process of manufacture).
(c) Number of passes for water in (each) heater.
(d) Method of and space required for removing and replacing tubes.
(e) Complete details of attachment of tubes to tube sheet(s).
(f) Diameter, length and thickness of shell(s).
(g) Thickness of tube sheet(s).
(h) Complete details of all gasket joints in (each) heater.
(i) Number and size of staybolts in (each) heater.
(j) Description of tools and accessories included.
(k) Complete manufacturer's specifications of the equipment.
(l) Water pressure drop through (each) heater under maximum operating conditions.
(m) Temperature of drips from (each) heater.
(n) Weight of (each) heater under operating conditions.
(o) Weight of (each) heater with steam and water spaces filled with water.
(p) Weight and size of largest piece.
(q) Shipping point.
(r) Date of shipment (and time necessary to complete erection).
(s) Per diem charge for services of Contractor's erector or representative not covered by the contract.
(t) Any other details wanted by Purchaser.

Specification

For Closed Heater(s) for Power House at (Philadelphia, Pa.)

(A.B.C. Power Company)
Specification No. (......)

(Philadelphia, Pa.)
(Date)

Scope

1. This specification covers the furnishing, (and delivery and erection) of (number) closed heater system(s) for the (new) (present) power plant of the (A. B. C. Power Co.) located at (Philadelphia, Pa.) The heater(s) shall be furnished (and installed) with all appurtenances directly a part thereof and necessary to place (them) in successful operation, with the exception of such appurtenances as may be herein otherwise provided for.

Service

2. The heater(s) will be used for heating boiler feed water by means of steam extracted from the main turbine(s) (and exhaust steam from auxiliary turbines) as shown on diagram(s) (numbers and titles) attached hereto.

3. ARRANGEMENT: (Each) system shall consist of (four) heater(s). (The condensate and air from each of the higher pressure heaters will be discharged into the next lower pressure heater). The air from the (low pressure) heater will be discharged (into the condenser) (by a steam jet air pump); the condensate will be (pumped to the boiler feed suction header) (drained to the condenser hot well).

4. OPERATING CONDITIONS: The design of (each) heater system shall be governed by the following (maximum) operating conditions:

	Heater A	Heater B	Heater C	Heater D
Water flow, lb. per hr.	(.....)	(.....)	(.....)	(.....)
Water inlet temperature, °F.	(.....)	(.....)	(.....)	(.....)
Water outlet temperature, °F.	(.....)	(.....)	(.....)	(.....)
Steam pressure, lb. per sq. in. abs	(.....)	(.....)	(.....)	(.....)
Total heat content of steam, B.t.u. per lb.	(.....)	(.....)	(.....)	(.....)
Drips to heater, lb. per hr.	(.....)	(.....)	(.....)	(.....)
Temperature of drips, °F.	(.....)	(.....)	(.....)	(.....)
Maximum quantity of steam vented from heater (lb. per hr.) (% of steam flow)	(.....)	(.....)	(.....)	(.....)

Description

5. Design and Construction—General: The heater(s) shall be designed and constructed in accordance with the A. S. M. E. Code for Unfired Pressure Vessels insofar as this code does not conflict with the laws and regulations prevailing at the place of installation. In addition, the heater(s) shall be capable of withstanding the collapsing pressure due to perfect vacuum.

6. Design and Construction—Details: The heater design and construction shall conform to the following requirements:

	Heater A	Heater B	Heater C	Heater D
Type	(vertical) (floating head)	(horizonal) (bowed tubes)	(............) (hairpin tubes)	(............) (............)
Tube sheet(s) material	(Muntz metal)	(Admiralty metal)	(............)	(............)
Tubes secured by	(rolling in)	(ferrules)	(metallic packing)	(............)
Tube packing	(............)	(fiber)	(metallic)	(corset lace)
Tube material	(Muntz metal)	(Admiralty metal)	(electrolytic copper)	(............)
Specification	(A. S. T. M.) (............)	(............)	(............)	(............)
Diameter, in.	(............)	(............)	(............)	(............)
Gage (B.W.G.) No.	(............)	(............)	(............)	(............)
Water box(es) material	(cast steel)	(cast iron)	(steel plate)	(............)
Water box cover(s) material	(cast steel)	(cast iron)	(steel plate)	(............)
Separate or integral with water box	(............)	(............)	(............)	(............)
Shell material	(cast iron)	(steel plate)	(............)	(............)
Joints	(............)	(welded)	(riveted)	(............)
Test pressure steam space, lb. per sq. in.	(............)	(............)	(............)	(............)
Water space, lb. per sq. in.	(............)	(............)	(............)	(............)
Steam connections, size, in.	(............)	(............)	(............)	(............)
Number	(............)	(............)	(............)	(............)
Water connection, size, in.	(............)	(............)	(............)	(............)

7. Hot Well(s): (Each) heater shall be provided with a hot well of not less than (....) gal. capacity, equipped with a (¾) in. gage glass and fitting.

8. Staybolts: Staybolts shall be (forged bronze) conforming to A. S. A. Specification (H7-1925) and so installed as to prevent leakage.

9. Pipe Connections: Outlets to which Purchaser's piping connects, (2) in. diameter and larger, shall be flanged. Welded necks on steel shell(s) shall be of extra heavy pipe with (steel) flanges (screwed and welded) on, face of flange to be not less than (7) in. from crown of sheet. Welded connections less than (2) in. diameter shall be extra heavy couplings retapped after welding. Flanged connection shall be faced, drilled and constructed in accordance with the A. S. A. American Standard for the pressure handled.

10. Bolts: Bolts for joints subjected to high pressure (300 lb. or more) shall be high temperature alloy studs with nuts at both ends. Where the flanged connections to the heater(s) require studs for attachment of Purchaser's piping, they shall be furnished with the heater(s) by the Contractor.

11. Tube Supports: (Cast Iron) tube support plate(s) shall be provided to give sufficient rigidity to the tubes. Holes in the tube support plate(s) shall be drilled and chamfered on both sides.

12. Heater Supports: (Saddles) (lugs) to support the heater(s) in (horizontal) (vertical) position, shall be provided by the Contractor.

13. Interchangeability: (Tube bundles of heaters A, B, C, D, shall be removable and interchangeable.)

14. Tools: The Contractor shall furnish one complete set of special tools and special wrenches necessary for the operation and maintenance of the equipment.

15. Material by Purchaser: The Purchaser will furnish and install the following:

(a) Foundations, foundation bolts, washers and grouting.
(b) All piping, valves and fittings.
(c) Insulating covering.
(d) Pumps and drainers.
(e) Heater tubes, in required straight lengths, f.o.b. ......

16. Painting: One shop coat of (flat black) paint shall be applied to (each) heater before shipment.

17. Erection: The (Contractor) shall be responsible for the erection of the heater(s) under the general direction of the Engineers.

Drawings

18. (Two) copies of certified drawings shall be submitted to the (Purchaser or his) Engineers for approval within (....) calendar days after contract is placed. The (Purchaser or his) Engineers will examine these certified drawings only for general design, general dimensions and apparent suitability, and will approve them or return them for changes desired. Such approval will not relieve the Con-

tractor of responsibility to furnish equipment which will perform successfully under the specified conditions. After drawings are approved (four) copies shall be furnished (as soon as possible). After installation is completed (two) more copies of corrected drawings shall be furnished.

19. (Two) copies of any special operating instructions shall be furnished to the (Engineers) when heater(s) (are) shipped.

Guarantee

20. The Contractor guarantees that the apparatus to be furnished will be free from all defects in design, workmanship and material, and will give successful service under the conditions required and specified. The Contractor agrees to replace f.o.b. (....), without expense to the Purchaser, any part of the apparatus which may prove defective within (....) year(s) after apparatus is placed in operation.

[NOTE: Purchaser may wish to insert here, or in the formal contract, a requirement for a broader guarantee, calling for the Contractor to be responsible for furnishing equipment which will perform successfully under the specified conditions and to make good, without cost to the Purchaser, any defects of whatever kind, even including removal of the entire equipment and replacement thereof by similar or differently designed apparatus, which will perform in successful manner.]

Tests

21. Purchaser's inspector shall have free access to the equipment during the process of its manufacture and construction.

22. After the heater(s) (have) been erected, all pressure parts shall be given a hydrostatic test at the test pressure specified in Paragraph 6, and any and all other tests as may be required by law or ordinance. All apparatus for these tests shall be furnished by the (Contractor).

23. If the Purchaser so desires, an acceptance test shall be run on (one of) the closed heater system(s) at the expense of the Purchaser and under the rules of the latest A. S. M. E. Test Code. This test shall be made within (180) days after the closed heater(s) (is) placed in service. The Contractor will be given an opportunity to have a representative present to see that the heater(s) (is) operated properly, and he will be given every opportunity to take observations or to apply any instruments desired, unless a different arrangement is made by mutual agreement. Should this test indicate that the equipment does not meet all guarantees included in the contract, the Contractor shall, at his own expense, make such other tests as may be necessary to show that the contract has been fulfilled.

[NOTE: It may be desirable under certain special conditions to add at this point a bonus and penalty clause or liquidated damages clause.]

DEAERATING (HEATER) EQUIPMENT

Instructions to Bidders

For Deaerating (Heater) Equipment for Power House at
(Philadelphia, Pa.)
(A.B.C. Power Company)
Specification No. (......)

(Philadelphia, Pa.)
(Date)

General

1. (Duplicate proposals will be received at the office of (the Purchasing agent of the A. B. C. Power Co. at Philadelphia, Pa.) up to 5 p.m., Nov. ....) for the work outlined in the inclosed specification.

2. Bid price shall be submitted on a sheet separate from all other data.

3. Bidders shall visit the site and familiarize themselves with every phase of the work before submitting proposals.

4. All drawings and specifications furnished with requests for bids shall remain the property of the (Purchaser), and shall be returned with the proposals.

5. The right is reserved to reject any or all bids.

6. The successful bidder shall enter into a written contract with the Purchaser for the performance of the work included in the specifications.

7. This contract will be drawn up by the (Purchaser) and will include (Purchaser's) and (Contractor's) Specifications, Instructions to Bidders and the "General Conditions" of the contract, copy of which is attached hereto. In case of conflict between (Purchaser's) and (Contractor's) specifications, the (Purchaser's) specification shall rule.

8. BOND: The successful bidder shall (....) be required to furnish a written bond, for the full amount of the contract price, to the Purchaser. The cost of this bond will be paid by the Purchaser.

9. FORM OF PROPOSAL: Bidders are requested to state a (lump sum price) for furnishing, (and delivering and erecting) the equipment specified.

10. Each proposal shall be accompanied by drawings giving general dimensions, and drawings or cuts showing in detail the construction of the equipment offered.

11. DELIVERY: Delivery (and completion of erection) desired (....).

12. FACILITIES:
   (a) The plant is located on the (B. & O.) Railroad (with a siding entering the plant).
   (b) Water will (....) be furnished (free) by the Purchaser.
   (c) Power will (....) be furnished (free) by the Purchaser.
   (d) Power available is (220) volts (a-c.) (60 cycles) (3 phase).

(e) Compressed air (at 100 lb.) will (....) be furnished (free) by the Purchaser.
(f) Crane of (....) ton capacity is available. Crane operator will (....) be furnished (free) by the Purchaser.
(g) Storage space will be available (inside the plant), or remote storage alongside the tracks of the (B. & O. Railroad) with-(out) store houses approximately (....) miles from the plant.
(h) Office space (with telephone, light and heat) will (....) be furnished (free) by the Purchaser.
(i) (Contractor) shall supply tool and work shanties, scaffolding and falsework.

13. SHIPPING: Purchaser will furnish shipping instructions.

14. UNLOADING: The (Purchaser) will unload materials delivered by the Contractor and (advance) (freight) (and carting charges). The (Contractor) shall assume all responsibility for care and protection of the same after unloading.

15. LABOR CONDITIONS: (Union) (Non-union) labor.

16. TERMS OF PAYMENT:

(....) per cent on receipt of (bill of lading) for (complete) shipment.
(....) per cent on completion of (....) per cent of erection.
(....) Per cent on completion of erection.
(....) per cent (....) days after acceptance by the (Engineers).

Information

17. The following information shall be given with each proposal and will be made a part of the contract entered into with the successful bidder:

(a) Sq. ft. of active heating or cooling surface; diameter, length, thickness and material of tubes; number of water passes and friction loss at maximum flow in (each) closed heater or condenser.
(b) Sq. ft. of tray surface in (each) shell.
(c) Steam loss, lb. per hr., from (each) vent condenser.
(d) Water pressure required at inlet to deaerating equipment.
(e) Method of and space required for removing trays or tubes from each portion of the equipment.
(f) Facilities provided for inspection and cleaning each portion of the equipment.
(g) Thickness of shell(s) and tube sheets.
(h) Size, number and description of safety valves, blow-off valves and float valves included.
(i) Description of tools and accessories included.
(j) Complete manufacturer's specifications of the equipment.
(k) Guaranteed performance of (each) (deaerator).
(l) Weight empty, weight operating and weight with all spaces full of water of each piece of equipment.
(m) Weight and size of largest piece.
(n) Shipping point.
(o) Date of shipment (and time necessary to complete erection).
(p) Per diem charge for services of Contractor's erector or representative not covered by the contract.
(q) Any other details wanted by Purchaser.

Specification

For Deaerating (Heater) Equipment for Power House at

(Philadelphia, Pa.)

(A.B.C. Power Company)

Specification No. (......)

(Philadelphia, Pa.)
(Date)

Scope

1. This specification covers the furnishing, (and delivery and erection) of (number) (deaerators) (deaerating heaters) for the (new) (present) power plant of the A. B. C. Power Co.) located at (Philadelphia, Pa.). (Deaerators) shall be furnished (and installed) with all appurtenances directly a part thereof and necessary to place (them) in successful operation, with the exception of such appurtenances as may be herein otherwise provided for.

Service

2. The (deaerators) shall remove the air from the boiler feed water and will be a part of the feed water system as shown on Heat Balance Diagram No. (....) attached hereto.

[NOTE: Where possible the diagram should show quantities and temperature of water or vapor passing through each part of the system under normal operating conditions.]

3. OPERATING CONDITIONS: The design of (each) (deaerator) shall be governed by the following operating conditions:

(a) Flow of water to (deaerator), lb. per hr.....	(¼Max.)	(½Max.)	(¾Max.)	(Max.)
Temperature of water to (deaerator), °F..	(......)	(......)	(......)	(......)
Pressure of steam to (deaerator), lb. per sq. in. abs.	(......)	(......)	(......)	(......)
Total heat content of steam to (deaerator), B.t.u. per lb..	(......)	(......)	(......)	(......)

(b) Introduction of (....) per cent make-up water at the (deaerator), supplied from (.... river) and having the following average analysis:

(............) (............)
(............) (............)

(c) Abnormal condenser leakage amounting to (....) per cent of the water passing through the (deaerator).
(d) (Cooling water at a temperature of 40-80 deg. fahr. will be available in quantities up to 200 gal. per min.).

Description

4. DESIGN AND CONSTRUCTION: All parts of the equipment shall be designed and constructed in accordance with the A.S.M.E. Code for Unfired Pressure Vessels insofar as this code does not conflict with the laws and regulations prevailing at the place of installation. All water passages of closed vent condensers or auxiliary heaters shall be designed for a test pressure of (200) lb. per sq. in. gage. The steam space of (each) (deaerator) shall be designed for a test pressure of (....) lb. per sq. in. gage.

5. CAPACITY: The (deaerators), when operating under specified maximum conditions, shall be capable of delivering feed water containing not more than (.03) c.c. of oxygen per litre, if provided with sufficient steam to heat the water to the boiling point.

6. ARRANGEMENT: The (deaerators) will receive feed water from (.. stage closed heater) and deliver water to (feed pumps) as indicated on Heat Balance Diagram. Heating steam will be supplied from (.. stage of the main turbine) (exhaust steam system).

7. FLOOR SPACE: Floor space (..) ft. by (..) ft. with a clearance height of (..) ft., including all aisle space necessary for operation and maintenance, is available for (each) (deaerator).

8. SHELL(S):
   (a) (Deaerator) shell(s) shall be (wrought iron) (Armco iron) (with riveted joints) (cast iron).
   (b) Water outlet(s) from deaerating equipment shall be large enough to permit water flow (100) per cent in excess of specified maximum without overflow.
   (c) (Each) (deaerator) (storage tank) shall have a hot water storage capacity of (....) gal.
   (d) Where water storage space is in separate tank(s), (this) tank(s), constructed of (wrought iron) (Armco iron), with all openings for (deaerator), overflow, outlet and float chamber connection(s), shall be furnished (and installed) by the (Contractor).

9. SPECIAL EQUIPMENT: (Each) (deaerator) (storage tank) shall be equipped with the following:
   (a) Balanced valve with by-pass, controlled by adjustable (external) float, for admission of make-up water to the feed water system.
   (b) Overflow for water storage space (for loop seal) (with float valve), having a minimum overflow capacity of (....) lb. per hr. under all conditions of operation. (Overflow float and valve shall be of the external adjustable type).
   (c) Safety valve(s) with a discharge capacity of (....) lb. per hr. at a pressure of (....) lb. per sq. in. gage.
   (d) Suitable air ejector equipment, if required by operating steam pressure.
   (e) Water gage glass and fittings to indicate water level in storage section of (deaerator).
   (f) Test kit for the determination of oxygen in feed water. (One required for each installation).

10. PIPING: The fellowing piping, suitable for the pressures handled, shall be furnished (and installed) by the Contractor as part of the deaerating equipment. All piping (2) in. diameter and larger shall be flanged.
   (a) All piping directly a part of the equipment.
   (b) (All interconnecting and by-pass piping between the various parts of the equipment furnished under this specification).

11. PIPE CONNECTIONS: Outlets to which Purchaser's piping connects, (2) in. diameter and larger, shall be flanged. All flanges, flanged fittings and flanged outlets shall be faced, drilled and constructed in accordance with the A. S. A. American Standard for the pressure handled. Welded necks on steel shell(s) shall be of extra heavy pipe with (steel) flanges (screwed and welded) on, face of flange to be not less than (7) in. from crown of sheet. Welded connections less than (2) in. diameter shall be extra heavy couplings retapped after welding.

12. SUPPORTS: All supports for (deaerators), including structural steel other than beams and columns forming part of the building structure, shall be furnished (and installed)by the (Contractor).

13. ACCESSIBILITY: All parts of the equipment shall be provided with a sufficient number of removable heads or doors, manholes and handholes to make the interior of each accessible for inspection, repair or for the removal of internal parts or foreign matter.

14. TOOLS: The Contractor shall furnish one complete set of special tools and wrenches necessary for the operation and maintenance of the equipment.

15. MATERIAL: Any part coming in contact with steam at a temperature above (450) deg. fahr. shall be of (steel, monel or ....).

16. MATERIAL BY PURCHASER: The Purchaser will furnish and install the following:
   (a) Foundations, foundation bolts, washers and grouting.
   (b) (All piping, valves and fittings extraneous to the deaerating equipment.)
   (c) Insulating covering.

17. PAINTING: All exposed castings which will not be insulated shall have (two) coats of filler rubbed smooth and shall be given one shop coat of flat paint. Exposed steel shall be given one shop coat of flat paint. All finished parts shall be slushed over before shipment (and cleaned by the Contractor after erection is completed).

18. ERECTION: The (Contractor) shall be responsible for the erection (and preliminary operation) of the equipment covered by this specification under the general direction of the (Engineers).

Drawings

19. (Two) copies of certified drawings shall be submitted to the (Purchaser or his) Engineers for approval within (....) calendar days after contract is placed. The (Purchaser or his) Engineers will examine these certified drawings only for general design, general dimensions and apparent suitability, and will approve them or return them for changes desired. Such approval will not relieve the Contractor of responsibility to furnish equipment which will perform successfully under the specified conditions. After drawings are approved (four) copies shall be furnished (as soon as possible). After installation is completed (two) more copies of corrected drawings shall be furnished.

20. (Two) copies of sectional views and lists of parts with piece numbers shown thereon shall be furnished the Purchaser to facilitate the ordering of repair parts.

21. (Two) copies of any special operating instructions shall be furnished to the (Engineers) when deaerating equipment is shipped.

Guarantee

22. The Contractor guarantees that the apparatus to be furnished will be free from all defects in design, workmanship and material, and will give successful service under the conditions required and specified. The Contractor agrees to replace f.o.b. (....), without expense to the Purchaser, any part of the apparatus which may prove defective within (....) year(s) after apparatus is placed in operation.

[NOTE: Purchaser may wish to insert here, or in the formal contract, a requirement for a broader guarantee, calling for the Contractor to be responsible for furnishing equipment which will perform successfully under the specified conditions and to make good, without cost to the Purchaser, any defects of whatever kind, even including removal of the entire equipment and replacement thereof by similar or differently designed apparatus, which will perform in successful manner.]

Tests

23. Purchaser's inspector shall have free access to the equipment during the process of its manufacture and construction.

24. After the deaerating equipment has been erected, all pressure parts shall be given a hydrostatic test at the test pressure specified in Paragraph 4, and any and all other tests as may be required by law or ordinance. All apparatus for these tests shall be furnished by the (Contractor).

25. If the Purchaser so desires, an acceptance test shall be run on (one of) the (deaerators) at the expense of the Purchaser and under the rules of the latest A. S. M. E. Test Code. This test shall be made within (180) days after the (deaerators) (is) placed in service. The Contractor will be given an opportunity to have a representative present to see that the equipment is operated properly, and he will be given every opportunity to take observations or to apply any instruments desired, unless a different arrangement is made by mutual agreement. Should this test indicate that the equipment does not meet all guarantees included in the contract, the Contractor shall, at his own expense, make such other tests as may be necessary to show that the contract has been fulfilled.

[NOTE: It may be desirable under certain special conditions to add at this point a bonus and penalty clause or liquidated damages clause.]

ANALYSIS OF PROPOSALS

On receiving bids it will be found that, with the large amount of information furnished by the bidders, the analysis of proposals requires a great deal of time.

With the completion of its work the Specifications Subcommittee wishes to suggest that the analysis of bids may be facilitated, especially if the purchasing of equipment is of frequent occurrence, by having the bidders fill in prepared forms for the information required.

One large member company has used such forms to great advantage. A separate form is required for each type of equipment. The form which they use for boilers is shown in Fig. 1, 2 and 3.

These forms are to be used as follows:

With the specifications for boilers include copies of sheets 101, 102 and 103, shown in Fig. 1, 2 and 3; each bidder is requested to fill in these forms and include them in his formal proposal. Preferably the forms should be on paper that permits blueprinting and for this purpose the information should be filled in by the bidder in India ink or with a reversed carbon back.

The purchaser, upon receipt of bids, trims the tabulation sheets (except one) along the central line and pastes them together so as to form a continuous tabulation as shown in Fig. 4,—this permits of easy comparison of the bids.

In placing an analysis of proposals before an executive it would probably be sufficient to give items No. 1 and 2 of sheet 101, together with comparison of performance characteristics. This information can be arranged in graphic form as shown in Fig. 5.

FIG. 5.

STANDARDS FOR USE IN DESIGN AND OPERATION OF MECHANICAL POWER PLANT EQUIPMENT

There are in more or less general use throughout the country, a large number of standards which have been formulated by various groups interested in the standardization of equipment or commodities. The accompanying Numerical List and Alphabetical Index of Standards have been compiled especially for the use of engineers interested in the design or operation of the mechanical equipment of power plants. In the present instance standards have been selected from those promulgated by several of the national bodies whose standardization work is most generally recognized and which seems to best cover the equipment and material in question.

American Standards Association

This organization was formed in 1918, as the American Engineering Standards Committee, for the purpose of unifying engineering and industrial standards along national lines.

The personnel of the Standards Council consists of representatives of the group of national organizations known as member-bodies. The functions of the Council are to formulate rules for the development of standards and for the constitution of committees; to approve, on behalf of the Association, such standards as it may find to be supported by a consensus, affirmatively expressed, of those substantially concerned with the standard; but not to formulate standards.

Sectional Committees are made up of representatives designated by the various bodies concerned with the project assigned to the committee and of additional specially qualified individuals. The actual formulation of a standard which is later to be approved by the American Standards Association, rests with the Sectional Committee. Sectional Committees may be established under the administrative support and direction of one or more of the bodies principally concerned, known as sponsors, or they may function autonomously with certain limitations.

Most of the departments of the Federal Government, national engineering societies and national industrial associations, as well as many industrial corporations and individual manufacturers, are actively cooperating with the Association. A most comprehensive program has been adopted whereby the standardization work of the many bodies concerned is being broadened and unified into a system of national industrial standards. The fundamental principle is that approval by the A. S. A. shall mean that a real national consensus has been reached.

Those of the standards officially approved and issued by the Association, which are pertinent, have been included in the accompanying list.

American Society for Testing Materials

Since its organization in 1898, this Society has built up a series of standard specifications, standard methods and recommended practices which have been very generally accepted. The Society is most actively identified with the work of the American Standards Association and a number of its standards have already received the approval of and have been issued by the Association.

As there are still many A. S. T. M. standards which have not yet been passed upon by the A. S. A., all those issued by the Society that apply to material required in the design or operation of the mechanical part of a power plant, have been included in the accompanying list.

The American Society of Mechanical Engineers

This Society has formulated and issued a number of rules and codes, as well as various standards, dealing with mechanical equipment. Those pertaining to power plants have been included in the accompanying list.

The Society is cooperating to the fullest extent with the American Standards Association and a number of its standards have already been adopted by the Association.

Federal Specifications Board

This Board, organized in 1921, and operating under the authority of the Bureau of the Budget, is composed of representatives of each of the purchasing units of the U. S. Government, the Chairman of the Board being the Director of the Bureau of Standards, ex officio. Its function is to unify the specifications of the many purchasing branches of the Government and to bring its specifications into harmony with the best commercial practice so as to broaden the field of supply. Cooperative arrangements between the Board and the A. S. A. have been made, whereby the Government specifications are being submitted, at first informally, for criticism by industry and to determine their acceptability to industry, and finally for approval as American Standards.

Those U. S. Government master specifications promulgated by the Board, which apply to mechanical power plant materials, have been included in the accompanying compilation. It is to be noted that in many instances these specifications, in addition to the F. S. B. number, bear also the circular number of the Bureau of Standards.

Bureau of Standards

The Bureau, as reorganized in 1927, now has a branch known as the Commercial Standards Group. This group is composed of (1) the Division of Simplified Practice, organized in 1921, whose function is the reduction of industrial waste through the elimination of unnecessary diversity in sizes, types, styles and other varieties of manufactured products; (2) a new Division of Specifications; (3) a new

---

Publication No. 289-50. Serial Report, Prime Movers Committee.

Commercial Standards Unit. The detailed functions of the two new divisions have not yet been announced, but apparently specifications issued by the Federal Specifications Board will be used as a principal means through which the Bureau will enter the field of industrial standardization.

Utilization of Standards

In utilizing these selected standards, it is suggested that, where possible, preference be given to those officially approved and issued by the A. S. A. For this reason, these are listed first under each item in the Alphabetical Index. In cases where no A. S. A. standards have yet been adopted, or where those already adopted do not cover the situation, standards issued by the A. S. T. M., the A. S. M. E. or the F. S. B. can be used.

The following abbreviations are used:

A. S. A. —American Standards Association.
A. S. T. M.—American Society for Testing Materials.
A. S. M. E.—The American Society of Mechanical Engineers.
F. S. B. —Federal Specifications Board.
B. of S. —Bureau of Standards.
B. of M. —Bureau of Mines.
Std. —Standard.
Tent. —Tentative.
Spec. —Specification.
Def. —Definition.
Rec. —Recommended.
Cir. —Circular.

How to Obtain Standards

For the guidance of those desiring to obtain copies of the various standards or more complete information on standardization, the following directions are given:

American Standards Association

Copies of American Engineering and Industrial Standards, officially approved by the A. S. A. are for sale at cost by the A. S. A. are for sale at cost by the American Standards Association, 29 West Thirty-ninth Street, New York, N. Y. A list of these approved standards, with prices, is issued periodically by the Association and can be obtained on application.

The Association has also arranged to act as a central distributing agent for the specifications of the national technical societies, trade associations, and the nineteen foreign standardizing bodies for the convenience of those who may wish to secure copies of these specifications from one rather than several sources.

A Year Book of the A. S. A. is issued annually. This contains a list of all projects which have an official status before the Association as well as various information regarding the work of the Association and standardization in general. The names and addresses of local Association representatives are also given.

American Society for Testing Materials

There is issued, as of September 1st each year, a pamphlet containing a complete list of A. S. T. M. Standards and Tentative Standards, as well as price list of the Society's publications. Copies of this may be had by application to the American Society for Testing Materials, 1315 Spruce Street, Philadelphia, Pa. Standards may be obtained individually at 25 cents per copy, or collectively in book form at prices given in price list.

The American Society of Mechanical Engineers

The A. S. M. E. issues periodical lists of the Society's publications with prices. These lists may be obtained by addressing the American Society of Mechanical Engineers, 29 West Thirty-ninth Street, New York, N. Y.

Federal Specifications Board

An Alphabetical Index and Numerical List of United States Government Master Specifications promulgated by the F. S. B. are issued annually by the Department of Commerce, as Circular of the Bureau of Standards No. 319, and may be obtained by addressing the Superintendent of Documents, Government Printing Office, Washington, D. C.

Specifications bearing only a Federal Specifications Board number are in mimeograph form and can be obtained, free upon request, from the Federal Specifications Board, care of Bureau of Standards, Washington, D. C.

Specifications bearing Bureau of Standards circular numbers or other bureau publication numbers in addition to the F. S. B. numbers are in printed form and must be purchased direct from the Superintendent of Documents. Orders for specifications must state the bureau publication numbers and must be addressed, accompanied by cash or money order, to the Superintendent of Documents, Government Printing Office, Washington, D. C. With a few exceptions noted in the published list, the price of each printed specification is 5 cents per copy.

Bureau of Standards

The Department of Commerce, Bureau of Standards issued, as Miscellaneous Publications No. 65, August 28, 1925, a National Directory of Commodity Specifications. This directory contains classified and alphabetical lists together with brief description of the then existing commodity specifications formulated not only by the public purchasing agencies throughout the United States, but also by the nationally recognized trade associations, technical societies and public utilities.

The directory may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., at the price of $1.25.

The Department of Commerce also issues annually, as Bureau of Standards Miscellaneous Publication No. 83, a Standards Yearbook. This publication deals with the general subject of standardization both in this country and abroad. Copies may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D. C., at the price of $1.00 each.

NUMERICAL LIST OF STANDARDS RELATING TO MECHANICAL EQUIPMENT OF POWER PLANTS

American Standards Association—American Engineering and Industrial Standards

Standard No.
A 14-1923—Ladders, Safety Code.
A 17-1925—Elevators and Escalators, Safety Code.

B 1a-1924—Screw Threads for Bolts, Machine Screws, Nuts and Commercially Tapped Holes.
B 2-1919—Pipe Thread.
B 4a-1925—Tolerances and Allowances for Machined Fits in Interchangeable Manufacture.
B 6b-1927—Tooth Form of Spur Gears.
B 15-1927—Power Transmission Apparatus, Mechanical, Safety Code.
B 16a-1928—Cast Iron Flanges and Flanged Fittings for Maximum Pressures of 125 lb.
B 16b-1928—Cast Iron Flanges and Flanged Fittings for Maximum Pressures of 250 lb.
B 16c-1927—Malleable Iron Screwed Fittings for Maximum Pressures of 150 lb.
B 16d-1927—Cast Iron Screwed Fittings for Maximum Pressures of 125 and 250 lb.
B 16e-1927—Steel Flanges and Flanged Fittings for Maximum Pressures of 250, 400, 600, 900 and 1350 lb.
B 17a-1924—Diameters and Lengths of Cold-Finished Shaftings.
B 17b-1925—Keys, Square and Flat Stock, Widths and Heights.
B 17c-1927—Design of Transmission Shafting, Code.
B 17d-1927—Keys, Plain Taper Stock, Square and Flat.
B 17e-1927—Keys, Gib Head, Taper Stock, Square and Flat.
B 18a-1927—Small Rivets.
B 18b-1927—Wrench Head Bolts and Nuts and Wrench Openings.
B 18e-1928—Round Unslotted Head Bolts.
G 9-1924—Forgings, Carbon-Steel and Alloy-Steel Blooms, Billets and Slabs for, Specifications.
G 12-1923—Bars, Refined, Wrought-Iron, Specifications.
G 13-1923—Plates, Wrought-Iron, Specifications.
H 7-1925—Brass Forging Rod, Specifications.
H 8-1925—Brass Rod, Free-Cutting for Use in Screw Machines, Specifications.
H 10-1924—Ingot Metal, Brass, for Sand Castings, Specifications.
K 3-1921—Manganese Bronze, Methods of Chemical Analysis.
K 5-1922—Alloys of Lead, Tin, Antimony and Copper, Chemical Analysis.
K 8-1923—Liquids, Volatile, Flammable, Method of Test for Flash Point.
K 12-1921—Copper, Methods for Battery Assay.
X 1-1921—Coal, Method of Sampling.
Z 11a-1928—Standard Abridged Volume Correction Table for Petroleum Oils.
Z 11b-1928—Viscosity of Petroleum Products and Lubricants.
Z 11c-1928—Penetration of Greases and Petrolatum.
Z 11e-1928—Cloud and Pour Points of Petroleum Products.
Z 11f-1928—Flash and Fire Points by Means of Open Cup.
Z 11g-1928—Flash Point by Means of the Pensky-Martens Closed Tester.
Z 11l-1928—Neutralization Number of Petroleum Products and Lubricants.
Z 11m-1928—*Sulfur* in Petroleum Oils Heavier Than Illuminating Oil.
Z 11n-1928—Thermal Value of Fuel Oil.
Z 11p-1928—Standard Method of Analysis of Grease.
Z 12a-1927—Installation of Pulverized Fuel Systems, Safety Code.

American Society for Testing Materials—Standards and Tentative Standards

Standard No.
*A 17-21—Std. Spec. for Carbon-Steel and Alloy-Steel Blooms, Billets, and Slabs for Forgings.
A 18-28—Std. Spec. for Carbon-Steel and Alloy-Steel Forgings.
A 27-24—Std. Spec. for Steel Castings.
A 31-24—Std. Spec. for Boiler Rivet Steel.
A 33-24—Std. Methods of Chemical Analysis of Plain Carbon-Steel.
A 33-28T—Tent. Methods of Sampling Rolled and Forged Steel Products for Check Analysis.
A 35-24—Rec. Practice for Annealing of Miscellaneous Rolled and Forged Carbon-Steel Objects.
A 36-24—Rec. Practice for Heat Treatment of Carbon-Steel Castings.
A 37-27—Rec. Practice for Carburizing and Heat Treatment of Carburized Objects.
*A 41-18—Std. Spec. for Refined Wrought-Iron Bars.
*A 42-18—Std. Spec. for Wrought-Iron Plates.
A 43-24—Std. Spec. for Foundry Pig Iron.
A 44-04—Std. Spec. for Cast-Iron Pipe and Special Castings.
A 47-27—Std. Spec. for Malleable Castings.
A 48-18—Std. Spec. for Gray-Iron Castings.
A 53-27—Std. Spec. for Welded and Seamless Steel Pipe.
A 55-24—Std. Methods of Chemical Analysis of Alloy Steels.
A 58-27—Std. Spec. for Carbon-Steel Bars for Vehicle and General Purpose Springs.
A 64-27—Std. Methods of Sampling and Chemical Analysis of Pig and Cast Iron.
A 70-27—Std. Spec. for Boiler and Firebox Steel for Stationary Service.
A 72-27—Std. Spec. for Welded Wrought-Iron Pipe.
A 78-27—Std. Spec. for Steel Plates of Structural Quality for Forged Welding.
A 81-27—Std. Def. of Terms Relating to Wrought-Iron Specifications.
A 83-27—Std. Spec. for Lap-Welded and Seamless Steel and Lap-Welded Iron Boiler Tubes.
A 84-27—Std. Spec. for Staybolt, Engine-Bolt and Extra Refined Wrought-Iron Bars.
A 85-27—Std. Spec. for Common Iron Bars.
A 86-27—Std. Spec. for Hollow Rolled Staybolt Iron.
A 88-24—Std. Spec. for High-Test Gray-Iron Castings.
A 89-27—Std. Spec. for Steel Plates of Flange Quality for Forge Welding.
A 95-28T—Tent. Spec. for Carbon-Steel Castings for Valves, Flanges and Fittings for High-Temperature Service.
A 96-27—Std. Spec. for Alloy-Steel Bolting Material for High-Temperature Service.
A 105-28—Std. Spec. for Forged or Rolled Steel Pipe Flanges for High-Temperature Service.
A 106-28T—Tent. Spec. for Lap-Welded and Seamless Steel Pipe for High-Temperature Service.
A 107-27—Std. Spec. for Commercial Quality Hot-Rolled Bar Steels.
A 108-27—Std. Spec. for Commercial Cold-Finished Bar Steels and Cold Finishing Shafting.
A 119-28T—Tent. Definitions of Terms Relating to Heat Treatment Operations (Especially as Related to Ferrous Alloys).
A 120-28T—Tent. Spec. for Lap-Welded and Seamless Steel Pipe, Black and Galvanized, for Ordinary Uses.
A 124-28T—Tent. Spec. for the Arbitration Test Bar and Tension Test Specimen for Cast Iron.
B 4-27—Std. Spec. for Lake Copper Wire Bars, Cakes, Slabs, Billets, Ingots and Ingot Bars.
B 5-27—Std. Spec. for Electrolytic Copper Wire Bars, Cakes, Slabs, Billets, Ingots and Ingot Bars.

---

* Approved by the American Standards Association.

Standard No.
B 7-27—Std. Spec. for Manganese-Bronze Ingots for Sand Castings.
B 10-18—Std. Spec. for the Alloy: Copper, 88 per cent; Tin, 10 per cent; Zinc, 2 per cent.
B 13-18—Std. Spec. for Seamless Copper Boiler Tubes.
B 14-18—Std. Spec. for Seamless Brass Boiler Tubes.
*B 15-18—Std. Spec. for Brass Forging Rod.
*B 16-18—Std. Spec. for Free-Cutting Brass Rod for Use in Screw Machines.

B 60-28—Std. Spec. for Sand Castings of the Alloy: Copper, 88 per cent; Tin, 8 per cent; Zinc, 4 per cent.
B 61-28—Std. Spec. for Steam or Valve Bronze Sand Castings.
B 62-28—Std. Spec. for Composition Brass or Ounce Metal Sand Castings.
B 65-28—Std. Spec. for Yellow Brass Sand Castings for General Purposes.
B 72-28T—Tent. Spec. for Fire-Refined Copper Other Than Lake.
B 74-28T—Tent. Spec. for Sand Castings of the Alloy: Copper, 80 per cent; Tin, 10 per cent; Lead, 10 per cent.
B 75-28T—Tent. Spec. for Seamless Copper Tubes.

C 16-20—Std. Method of Test for Refractory Materials Under Load at High Temperatures.
C 18-21—Std. Methods of Ultimate Chemical Analysis of Refractory Materials, Including Chrome Ores and Chrome Brick.
C 20-20—Std. Method of Test for Porosity and Permanent Volume Changes in Refractory Materials.
C 24-28—Std. Method of Test for Softening Point of Fire-Clay Brick.
C 25-27T—Tent. Methods of Chemical Analysis of Limestone, Quicklime and Hydrated Lime.
C 27-28—Std. Def. for Clay Refractories.
C 38-27T—Tent. Method of Test for Resistance of Fire-Clay Brick to Thermal Spalling Action.
C 49-24—Std. Spec. for Quicklime and Hydrated Lime for the Manufacture of Silica Brick.
C 50-27—Std. Methods of Sampling, Inspection, Packing and Marking of Quicklime and Lime Products.
C 51-28—Std. Def. of Terms Relating to Lime.
C 53-27—Std. Spec. for Quicklime for Use in Water Treatment.
C 54-27—Std. Spec. for Hydrated Lime for Use in Water Treatment.

Standard No.
C 55-28T—Tent. Spec. for Concrete Building Brick.
C 62-28T—Tent. Spec. for Building Brick (Made from Clay or Shale).
C 64-28—Std. Spec. for Clay Fire Brick for Stationary Boiler Service.
C 67-28T—Tent. Methods of Testing Brick.
C 71-28—Std. Def. of Terms Relating to Refractories.
C 71-28T—Tent. Def. of Terms Relating to Refractories.
C 73-28T—Tent. Spec. for Sand-Lime Building Brick.

D 13-26—Std. Spec. for Gum Spirits of Turpentine and Steam-Distilled Wood Turpentine.
D 15-24—Std. Method of Testing Rubber Products.
D 16-24—Std. Def. of Terms Relating to Paint Specifications.
*D 21-16—Std. Method of Sampling Coal.
D 34-27—Std. Methods of Routine Analysis of White Pigments.
D 46-24—Std. Spec. for Wrapped Air Hose for Use with Pneumatic Tools.
D 49-28—Std. Methods of Routine Analysis of Dry Red Lead.
D 54-24T—Tent. Spec. for Steam Hose.
D 56-21—Std. Method of Test for Flash Point of Volatile Flammable Liquids.
D 60-24—Std. Spec. for Braided Air Hose for Use with Pneumatic Tools.
D 79-24—Std. Spec. for Zinc Oxide.
D 80-24—Std. Spec. for Leaded Zinc Oxide.
D 81-24—Std. Spec. for Basic Carbonate White Lead.
D 82-24—Std. Spec. for Basic Sulfate White Lead.
D 83-24—Std. Spec. for Red Lead.
D 84-27—Std. Spec. for Mineral Iron Oxide.
*D 88-26—Std. Methods of Test for Viscosity of Petroleum Products and Lubricants.
D 91-21T—Tent. Method of Test for Precipitation Number of Lubricating Oils.
*D 92-24—Std. Method of Test for Flash and Fire Points by Means of Open Cup.
*D 93-22—Std. Method of Test for Flash Point by Means of the Pensky-Martens Closed Tester.
D 94-28—Std. Method of Test for Saponification Number.
D 95-28—Std. Method of Test for Water in Petroleum Products and Other Bituminous Materials.
D 96-28—Std. Method of Test for Water and Sediment in Petroleum Products by Means of Centrifuge.
*D 97-28—Std. Method of Test for Cloud and Pour Points of Petroleum Products.
D 121-27—Std. Def. of Terms Relating to Coal and Coke.
D 121-27T—Tent. Def. of Terms Relating to Coal and Coke.
*D 128-27—Std. Method of Analysis of Grease.
*D 129-27—Std. Method of Test for Sulfur in Petroleum Oils Heavier Than Illuminating Oil.
D 151-23—Std. Spec. for Rubber Pump Valves.
D 154-28—Std. Methods of Testing Oleo-Resinous Varnishes.
D 155-23T—Tent. Method of Test for Color of Lubricating Oils by Means of Union Colorimeter.
D 157-28 Std. Method of Test for Steam Emulsion of Lubricating Oils.
D 177-24—Std. Spec. for Wrapped Cold Water Hose.
D 182-25—Std. Spec. for A.S.T.M. Partial-Immersion Thermometer for General Use, —20 to +150 deg. cent., 0 to +300 deg. fahr.
D 183-25—Std. Spec. for A.S.T.M. Partial-Immersion Thermometer for General Use, —5 to +300 deg. cent., +20 to +580 deg. fahr.
D 184-25—Std. Spec. for A.S.T.M. Partial-Immersion Thermometer for General Use, —5 to +400 deg. cent., +20 to +760 deg. fahr.
*D 188-27T—Tent. Method of Test for Neutralization Number of Petroleum Products and Lubricants.
D 189-28—Std. Method of Test for Carbon Residue of Petroleum Products (Conradson Carbon Residue).
D 197-26T—Tent. Method of Test for Fineness of Powdered Coal.

---

*Approved by the American Standards Association.

Standard No.
*D 206-25—Std. Abridged Volume Correction Table for Petroleum Oils.
D 215-28T—Tent. Methods of Routine Analysis of White Linseed Oil Paints.
*D 217-27T—Tent. Method of Test for Penetration of Greases and Petrolatum.
D 233-26—Std. Methods of Sampling and Testing Turpentine.
D 234-28—Std. Spec. for Raw Linseed Oil.
D 235-26T—Tent. Spec. for Petroleum Spirits (Mineral Spirits).
D 236-27—Std. Spec. for Destructively Distilled Wood Turpentine.
*D 240-27—Std. Method of Test for Thermal Value of Fuel Oil.
D 260-28T—Tent. Spec. for Boiled Linseed Oil.
D 266-28T—Tent. Spec. for Aluminum Powder for Paints (Aluminum Bronze Powder).
D 267-28T—Tent. Spec. for Gold Bronze Powder.
D 270-27T—Tent. Methods of Sampling Petroleum and Petroleum Products.
D 271-27—Std. Methods of Laboratory Sampling and Analysis of Coal and Coke.
D 271-27T—Tent. Methods for the Determination of Sulfur in Coal and Coke by the Bomb-Washing and Sodium Peroxide Fusion Methods.
D 277-28T—Tent. Spec. for the Toxic Ingredients in Anti-Fouling Paints.
D 286-28T—Tent. Method of Test for the Termination of Autogenous Ignition Temperatures.
D 287-28T—Tent. Method of Test for Gravity of Petroleum and Petroleum Products by Means of the Hydrometer.
D 288-28T—Tent. Def. of Terms Relating to Petroleum.
D 291-28T—Tent. Method of Test for Cubic Foot Weight of Crushed Bituminous Coal.
D 297-28T—Tent. Methods of Chemical Analysis of Rubber Products.

E 2-27—Std. Rules Governing the Preparation of Micrographs of Metals and Alloys, Including Recommended Practice for Photography as Applied to Metallography.
E 3-24—Std. Methods of Metallographic Testing of Iron and Steel.
E 5-27—Std. Methods of Metallographic Testing of Non-Ferrous Metals and Alloys.
E 6-25T—Tent. Def. of Terms Relating to Methods of Testing.
E 7-27—Std. Def. of Terms Relating to Metallography.
E 8-27T—Tent. Methods of Tension Testing of Metallic Materials.
E 9-27T—Tent. Methods of Compression Testing of Metallic Materials.
E 10-27—Std. Methods of Brinell Hardness Testing of Metallic Materials.
E 14-25T—Tent. Rec. Practice for Thermal Analysis of Steel.
E 15-26T—Tent. Rec. Practice for Radiographic Testing of Metal Castings.

The American Society of Mechanical Engineers Codes and Standards

Construction and Operation Codes
- Boiler Construction Code.
- Suggested Rules for Care of Power Boilers.
- Rules for the Construction of Unfired Pressure Vessels.
- Safety Code for Elevators.
- Safety Code for Mechanical Power Transmission Apparatus.
- *Code for Design of Transmission Shafting.
- Code on Instruments and Apparatus, Part 1, General Considerations.

Power Test Codes
- Definitions and Values.
- General Instructions.
- Centrifugal and Rotary Pumps.
- Condensing Apparatus.
- Displacement Compressors and Blowers.
- Evaporating Apparatus.
- Feedwater Heaters.
- Reciprocating Steam-Driven Displacement Pumps.
- Reciprocating Steam Engines.
- Solid Fuels.
- Speed Responsive Governors.
- Stationary Steam Boilers.
- Steam Turbines.
- Fan Section.

Standards
- *Tolerances, Allowances and Gages for Metal Fits.
- *American Standard Screw Threads for Bolts, Machine Screws, Nuts and Commercially Tapped Holes.
- Standardization of Shafting.
  - a. *Shafting Diameters.
  - b. *Square and Flat Stock Keys.
  - c. *Plain Taper Stock Keys.
  - d. *Gib Head Taper Stock Keys.
- *Spur Gear Tooth Form.
- *Small Rivets.
- *Wrench Head Bolts and Nuts and Wrench Openings.
- American Standards for Pipe Flanges and Fittings.
  - a. *Steel Pipe Flanges and Flanged Fittings for maximum working steam pressures of 250, 400, 600, 900 and 1350 lb. per sq. in.
  - b. *Cast Iron Pipe Flanges and Flanged Fittings, all sizes for maximum working saturated steam pressures of 125 and 250 lb. per sq. in.
  - c. *Cast Iron Screwed Fittings, for maximum working saturated steam pressures of 125 and 250 lb. per sq. in.
  - d. *Malleable Iron Screwed Fittings, for maximum working saturated steam pressures of 150 lb. per sq. in.
- Bibliography on Mechanical Springs.

Federal Specifications Board—United States Government Master Specifications

F.S.B. Spec. No.	B. of S. Cir. No.	
2d	†	Lubricants and liquid fuels and methods for sampling and testing.
4b	C82	Linseed oil, raw.
5	C84	Basic carbonate white lead, dry and paste.
6	C85	Basic sulphate white lead, dry and paste.
7b	C86	Turpentine (gum spirits of turpentine and steam-distilled wood turpentine).
8	C87	Zinc oxide, dry and paste.
9	C88	Leaded zinc oxide, dry and paste.
10b	C89	White paint and tinted paints made on a white base, semi-paste and ready mixed.
11	C90	Red lead, dry and paste.
13b	C93	Iron oxide and iron hydroxide paints.
14b	C94	Black paint, semi-paste and ready mixed.
15	C97	Green paint, semi-paste and ready mixed.
16	C98	Volatile mineral spirits for thinning paints.
17	C102	Composite vehicle for thinning semi-paste paints when the use of straight linseed oil is not justified.
18b	C103	Spar varnish, water resisting.
19	C104	Asphalt varnish.
20	C105	Liquid paint drier.
37	C148	Leather belting.
40b	C290	Gas hose.
41b	C307	Pneumatic hose.
48b	C291	Water and wash deck hose.
49b	C268	Steam hose.
50a	C292	Water suction hose (smooth bore).
57	...	Flexible non-metallic tubing.

---

*Approved by the American Standards Association.
†Bureau of Mines Technical Paper No. 323B.

F.S.B. Spec. No.	B. of S. Cir. No.	
59a	C232	General specifications for rubber goods (methods of physical tests and chemical analysis).
63b	C209	Oil hose, suction and discharge.
66	C146	Water-resisting red enamel.
89	...	Manganese bronze ingots (for remelting).
93	...	Corrugated asbestos-copper gaskets.
94b	C243	Asbestos metallic cloth sheet packing.
95	...	Asbestos valve-stem packing.
96c	...	Compressed asbestos sheet packing.
97b	C242	Asbestos metallic cloth gaskets.
98a	C240	Diaphragm packing.
99	...	Fabric condenser-tube packing.
100	...	Fiber packing for lubricating and fuel oil.
101c	...	Flax packing.
102	...	Flexible metallic packing.
103a	C238	Asbestos high-pressure rod packing.
104a	C237	Low-pressure spiral-gland packing.
105	...	Metallic packing (fixed-ring type).
106	...	Plastic metallic packing.
107	...	Semi-metallic packing.
108	...	Solid metallic packing (floating-ring type).
110a	C236	Cloth-insertion rubber packing.
111a	C235	Rubber packings and gaskets (molded, sheet and strip).
112a	C234	Wire-insertion rubber packing.
113a	C233	Tucks packing.
114a	C244	Rubber valves.
120	...	Ingot copper.
126a	...	Foundry pig iron.
137a	C165	Olive-drab paint, semi-paste and ready mixed.
140	...	High-test gray-iron castings (semi-steel).
141	...	Gray-iron castings.
158	...	Hair felt.
162a	...	Welded steel pipe (black and galvanized).
170	...	Steel castings.
172a	...	Bronze castings.
174	...	Welding wire, iron and steel.
184	C213	Lace leather.
211	...	Magnesia-asbestos plaster.
212	...	Magnesia molded pipe covering and blocks.
238	...	Pipe threads.
239	C200	Heavy rust-preventive compound.
242	...	Welded wrought iron pipe (black and galvanized).
259a	C261	Cotton rags, colored, for wiping machinery (sterilized).
261a	C264	Cotton rags, white, for wiping machinery (sterilized).
262a	C262	Cotton waste, white.
263a	C263	Cotton waste, colored.
264a	C260	Wool waste, colored.
268a	C299	Fire-clay brick.
269	...	Welding rods, non-ferrous, for gas welding.
272	...	Brass castings, naval and commercial.
286	...	Brass castings to be brazed.
287	...	Seamless copper tubing and pipe, standard iron pipe size.
290a	...	Bronze ingots (for remelting).
293	C214	Medium and light rust-preventive compounds.
314	...	Railroad track scales.
316	...	Steel blooms, billets, slabs and bars, for reforging, carbon and alloy.
334a	C298	Fire clay.
335a	C297	Plastic fire-clay refractories.
339	...	General specification for metals.
342a	...	Seamless brass pipe, iron pipe size, standard and extra strong.
347	...	Lapwelded and seamless steel boiler tubes.
349	...	Lapwelded charcoal iron boiler tubes.
370	...	Manganese bronze castings.
371	...	Nickel (for remelting).
374	...	Admiralty metal condenser tubes and tubes for ferrule stock.
378a	...	Malleable iron castings.
388	...	Emery cloth.
391	...	Refined wrought iron bar.
392	...	Brass rods, bars, shapes, plates, sheets and strips, commercial.
393	...	Malleable iron or steel unions.
427	...	Seamless brass tubing.
429	C314	Soda ash.
466	...	Conveyor belting (stitched duck).
467	...	Copper rods, bars, shapes, plates, sheets and strips.
472	...	Industrial thermometers.
475b	C330	Linseed oil, boiled.
485	C336	Metallic encased gaskets.
486	C335	Hard fiber sheet packing.
487	C334	Asbestos wick and rope packings.
489	...	Cast-iron pipe fittings (threaded).
496	C340	Hydraulic leather packing (vegetable tanned).
504	C345	Common clay brick.
505	C347	Common sand-lime brick.
532	...	Phosphor bronze spring wire.
535	...	Malleable iron pipe fittings (threaded) (150 lb.).
536	...	Anti-friction metal ingots and castings.
537	...	Centrifugally cast iron water pipe.
548	...	Bolts, nuts and machine screws.
550	...	Boiler staybolt steel.
552	...	Manganese bronze rods, bars, shapes and plates.
578	...	Copper castings, nickel alloy.

Bricks and Refractories
A.S.T.M. C16-20—Std. Method of Test for Refractory Materials Under Load at High Temperatures.
A.S.T.M. C18-21—Std. Methods of Ultimate Chemical Analysis of Refractory Materials, Including Chrome Ores and Chrome Bricks.
A.S.T.M. C20-20—Std. Method of Test for Porosity and Permanent Volume Changes in Refractory Materials.
A.S.T.M. C24-28—Std. Method of Test for Softening Point of Fire-Clay Brick.
A.S.T.M. C27-28—Std. Def. for Clay Refractories.
A.S.T.M. C38-27T—Tent. Method of Test for Resistance and Fire-Clay Brick to Thermal Spalling Action.
A.S.T.M. C55-28T—Tent. Spec. for Concrete Building Brick.
A.S.T.M. C62-28T—Tent. Spec. for Building Brick (Made from Clay or Shale).
A.S.T.M. C64-28—Std. Spec. for Clay Fire Brick for Stationary Boiler Service.
A.S.T.M. C67-28T—Tent. Methods of Testing Brick.
A.S.T.M. C71-28—Std. Def. of Terms Relating to Refractories.
A.S.T.M. C71-28T—Tent. Def. of Terms Relating to Refractories.
A.S.T.M. C73-28T—Tent. Spec. for Sand-Lime Building Brick.
F.S.B. 268a—Fire-Clay Brick (B. of S. Cir. No. C299).
F.S.B. 334a—Fire Clay (B. of S. Cir. No. C298).
F.S.B. 335a—Plastic Fire-Clay Refractories (B. of S. Cir. No. C297).
F.S.B. 504 —Common Clay Brick (B. of S. Cir. No. C345).
F.S.B. 505 —Common Sand-Lime Brick (B. of S. Cir. No. C347).
Bronze (See Non-Ferrous Metals).

Carburizing (See Steel).
Castings
A.S.T.M. A27-24—Std. Spec. for Steel Castings.
A.S.T.M. A36-24—Rec. Practice for Heat Treatment of Carbon-Steel Castings.
A.S.T.M. A44-04—Std. Spec. for Cast-Iron Pipe and Special Castings.
A.S.T.M. A47-27—Std. Spec. for Malleable Castings.
A.S.T.M. A48-18—Std. Spec. for Gray-Iron Castings.
A.S.T.M. A88-24—Std. Spec. for High-Test Gray-Iron Castings.
A.S.T.M. A95-28T—Tent. Spec. for Carbon-Steel Castings for Valves, Flanges and Fittings for High-Temperature Service.
A.S.T.M. B54-27—Std. Spec. for Manganese-Bronze Sand Castings.
A.S.T.M. B60-28—Std. Spec. for Sand Castings of the Alloy: Copper, 88 per cent; Tin, 8 per cent; Zinc, 4 per cent.
A.S.T.M. B61-28—Std. Spec. for Steam or Valve Bronze Sand Castings.
A.S.T.M. B62-28—Std. Spec. for Composition Brass or Ounce Metal Sand Castings.
A.S.T.M. B65-28—Std. Spec. for Yellow Brass Sand Castings for General Purposes.
A.S.T.M. B74-28T—Tent. Spec. for Sand Castings of the Alloy: Copper, 80 per cent; Tin, 10 per cent; Lead, 10 per cent.
A.S.T.M. E15-26T—Tent. Rec. Practice for Radiographic Testing of Metal Castings.
F.S.B. 140 —High-test gray-iron castings (semi-steel).
F.S.B. 141 —Gray-iron castings.
F.S.B. 170 —Steel castings.
F.S.B. 172a—Bronze castings.
F.S.B. 272 —Brass castings, naval and commercial.
F.S.B. 286 —Brass castings to be brazed.
F.S.B. 370 —Manganese bronze castings.
F.S.B. 378a—Malleable iron castings.
F.S.B. 578 —Copper castings, nickel alloy.
Castings, Metals (See Cast Iron and Non-Ferrous Metals).
Cast Iron
A.S.T.M. A43-24—Std. Spec. for Foundry Pig Iron.
A.S.T.M. A64-27—Std. Methods of Sampling and Chemical Analysis of Pig and Cast Iron.
A.S.T.M. A124-28T—Tent. Spec. for the Arbitration Test Bar and Tension Test Specimen for Cast Iron.
F.S.B. 126a—Foundry Pig Iron.
Cast Iron Castings (See Castings).
Cast Iron Pipe (See Castings and Tubes and Pipe, Cast Iron).
Cast Iron Pipe Flanges and Fittings (See Pipe Flanges and Fittings).
Chemicals
A.S.T.M. C25-27T—Tent. Methods of Chemical Analysis of Limestone, Quicklime and Hydrated Lime.
A.S.T.M. C49-24—Std. Spec. for Quicklime and Hydrated Lime for the Manufacture of Silica Brick.
A.S.T.M. C50-27—Std. Methods of Sampling, Inspection, Packing and Marking of Quicklime and Lime Products.
A.S.T.M. C51-28—Std. Def. of Terms Relating to Lime.
A.S.T.M. C53-27—Std. Spec. for Quicklime for Use in Water Treatment.
A.S.T.M. C54-27—Std. Spec. for Hydrated Lime for Use in Water Treatment.
F.S.B. 429—Soda Ash (B. of S. Cir No. C314).
Coal
A.S.A. X1-1921— Coal, Method of Sampling.
A.S.A. Z12a-1927—Investigation of Pulverized Fuel Systems, Safety Code.
A.S.T.M. *D21-16—Std. Method of Sampling Coal.
A.S.T.M. D121-27—Std. Def. of Terms Relating to Coal and Coke.
A.S.T.M. D121-27T—Tent. Def. of Terms Relating to Coal and Coke.
A.S.T.M. D197-26T—Tent. Method of Test for Fineness of Powdered Coal
A.S.T.M. D271-27—Std. Methods of Laboratory Sampling and Analysis of Coal and Coke.
A.S.T.M. D271-27T—Tent. Methods for the Determination of Sulfur in Coal and Coke by the Bomb-Washing and Sodium Peroxide Fusion Methods.
A.S.T.M. D291-28T—Tent. Method of Test for Cubic Foot Weight of Crushed Bituminous Coal.

REPORTS OF INVESTIGATIONS

Investigations by Government Bureaus

Among the Government publications which present the results of scientific and technical investigations and research made by the various Government Bureaus, there are some which should be of particular interest to engineers engaged in the design or operation of the mechanical equipment of power plants. While not coming strictly under the head of standards, a number of these publications, covering investigations by the Bureau of Standards and the Bureau of Mines, are included in separate lists for the convenience of those interested.

Prices of publications of the Bureau of Standards included in accompanying list and available for distribution, are given in Price List 64, Standards of Weight and Measure. This price list, which can be obtained by addressing the Superintendent of Documents, Government Printing Office, Washington, D. C., also gives an alphabetical list, with prices, of a large number of other publications on engineering subjects.

A General List of Publications of the Bureau of Mines, with prices, as well as an Index of Bureau of Mines Publications are issued by the Bureau. Copies can be had by applying to the Superintendent of Documents, Government Printing Office, Washington, D. C. Those publications of the Bureau that deal with the safety and health of workmen in the mineral industries or relate essentially to the conservation of mineral resources are printed for free distribution to residents of the United States and its possessions.

The publications of the Bureau of Standards and those of the Bureau of Mines indicated in accompanying list as obtainable only through the Superintendent of Documents, must be ordered from the Superintendent of Documents, Government Printing Office, Washington, D. C. Prepayment of price is required and should be made in cash (exact amount) or by postal or express money order, payable to the Superintendent of Documents.

Publications of the Bureau of Mines available for free distribution should be ordered by number and title from the Section of Publications, Bureau of Mines, Washington, D. C. No publications are sold by the Bureau and no money for publications should be sent to it.

Publications indicated in the list as out of print can not be supplied by the Bureau of Mines or the Superintendent of Documents. Copies of these publications were widely distributed to public libraries and can probably be consulted there.

Bureau of Standards Publications Relating to Mechanical Equipment of Power Plants

Circulars

8—Testing of Thermometers.
18—Standard Gage for Sheet and Plate Iron and Steel.
38—Testing of Rubber Goods.
42—Metallographic Testing.
69—Paint and Varnish.
73—Copper.
83—Specifications for Manufacture and Installation of Railroad Track Scales.
99—Carbonization of Lubricating Oils.
100—Nickel.
101—Physical Properties of Materials: 1, Strengths and Related Properties of Metals and Certain Other Engineering Materials.
106—Lime, Definitions and Specifications.
109—Sand-lime Brick, Description and Specification.
113—Structure and Related Properties of Metals.
150—Quicklime and Hydrated Lime for Use in Manufacture of Sand-lime Brick.
153—Quicklime and hydrated Lime for Manufacture of Silica Brick.
154—National Standard Petroleum Oil Tables.
Sup.—Abridged Volume Correction Table for Petroleum Oils.
231—Quicklime and Hydrated Lime for Use in Purification of Water.
282—Fire-clay Brick, Their Manufacture, Properties, Uses and Specifications.
333—Specifications for Manufacture and Installation of Two-section, Knife-edge Railroad Track Scales.

Technologic Papers

53—Investigation of Fusible Tin Boiler Plugs.
76—Determination of Volatile Thinner in Oil Varnish.
84—Failure of Brass: 3, Initial Stress Produced by the Burning in of Manganese Bronze.
85—Manufacture and Properties of Sand-lime Brick.
97—Some Unusual Features in Microstructure of Wrought Iron.
112—Standardization of the Saybolt Universal Viscosimeter.
116—Silica Refractories, Factors Affecting Their Quality and Methods of Testing the Raw Materials and Finished Ware.
124—Constitution and Microstructure of Silica Brick and Changes Involved Through Repeated Burnings at High Temperatures.
159—Porosity and Volume Changes of Clay Fire Bricks at Furnace Temperatures.
163—Stresses Caused by Cold-rolling.
176—Slushing Oils.
179—Electric Arc Welding of Steel: 1, Properties of the Arc-fused Metal.

188—Some Properties of White Metal Bearing Alloys at Elevated Temperatures.
201—Friction and Carrying Capacity of Ball and Roller Bearings.
206—Effect of Heat Treatment on the Mechanical Properties of 1 per cent Carbon Steel.
219—Effect of Temperature, Deformation, and Rate of Loading on the Tensile Properties of Low-carbon Steel Below Thermal Critical Range.
243—Stresses in a Few Welded and Riveted Tanks Tested Under Hydrostatic Pressure.
245—Embrittlement of Malleable Cast Iron Resulting from Heat Treatment.
252—Nick-bend Test for Wrought Iron.
254—Emissive Tests of Paints for Decreasing or Increasing Heat Radiation from Surfaces.
257—Development of Method for Measurement of Internal Stress in Brass Tubing.
267—Effect of Hot-rolling Conditions on Physical Properties of Carbon Steel.
274—Use of United States Government Specification Paints and Paint Materials.
279—Testing of Fire-clay Brick with Special Reference to Their Use in Coal-fired Boiler Settings.
281—Malleability and Metallography of Nickel.
285—Release of Internal Stress in Brass Tubing.
289—Comparative Slow Bend and Impact Notched Bar Tests on Some Metals.
296—Flow in Low-carbon Steel at Various Temperatures.
306—Photometric Method for Measuring Hiding Power of Paints.
308—Cement-lime Mortars.
334—Relationships Between Rockwell and Brinell Numbers (in Comparing Hardness of Ferrous and Non-ferrous Metals).
358—Air-hardening Rivet Steels.

Scientific Papers

356—Microstructure of Iron and Mild Steel at High Temperatures.
410—Thermal Expansion of Copper and Some of its Important Industrial Alloys.
426—Thermal Expansion of Nickel, and Monel Metal, Stellite, Stainless Steel, and Aluminum.
562—Density of Hot-rolled and Heat-treated Carbon Steels.
570—Thermal Expansion of Alloys of Stainless Iron Type.

Miscellaneous Publications

15—Some Technical Methods of Testing Miscellaneous Supplies Including Paints and Paint Materials, Inks, Lubricating Oils, Soaps, etc.

Investigations by College Engineering Experiment Stations

Some thirty-three engineering colleges connected with State institutions maintain engineering experiment stations which carry on investigations of value

---

*Obtainable only through the Superintendent of Documents, Government Printing Office, Washington, D. C.
**Out of print.

to the public. The Engineering Experiment Stations of the University of Illinois, Iowa State College, Ohio State University, Purdue University, University of Washington, University of Kansas, Pennsylvania State College and of several other State universities have made investigations of direct interest to the power industry.

Lists of publications, giving the results of their investigations, are issued by the various Engineering Experiment Stations and may be had on application to their Directors. While available these publications are generally subject to free distribution within certain limitations, or they may be obtained at prices indicated in the published lists.

The following bulletins are among those issued by the several Stations which apply particularly to mechanical power plant equipment. It will be noted that some of these are no longer available for general distribution.

University of Illinois

Bulletin No. 34—Tests of Two Types of Tile-Roof Furnaces under a Water-Tube Boiler. 1909.
Bulletin No. 36—The Thermal Conductivity of Fire-Clay at High Temperatures. 1909.
Bulletin No. *37—Unit Coal and the Composition of Coal Ash. 1909.
Bulletin No. 45—The Strength of Oxyacetylene Welds in Steel. 1910.
Bulletin No. 78—A Study of Boiler Losses. 1915.
Bulletin No. 94—The Embrittling Action of Sodium Hydroxide on Soft Steel. 1917.
Bulletin No. 98—Tests of Oxyacetylene Welded Joints in Steel Plates. 1917.
Bulletin No. *117—Emissivity of Heat from Various Surfaces. 1920.
Bulletin No. 128—The Ignition Temperature of Coal. 1922.
Bulletin No. 139—An Investigation of the Maximum Temperatures and Pressures Attainable in the Combustion of Gaseous and Liquid Fuels. 1924.
Bulletin No. 149—An Investigation of the Efficiency and Durability of Spur Gears. 1925.
Bulletin No. 155—The Cause and Prevention of Embrittlement of Boiler Plate. 1926.
Bulletin No. 168—Heat Transmission Through Boiler Tubes. 1927.
Bulletin No. 177—Embrittlement of Boiler Plate. 1928.
Bulletin No. 180—The Classification of Coal. 1928.
Bulletin No. 181—The Thermal Expansion of Fire-clay Bricks. 1928.
Bulletin No. 183—Tests of the Fatigue Strength of Steam Turbine Blade Shapes. 1928.

Iowa State College

Bulletin No. 54—An Investigation of the Protective Values of Structural Steel Paints.
Bulletin No. 71—The Mechanism for the Graphitization of White Cast Iron and Its Application to the Malleabilization Process.

Ohio State University

Bulletin No. *4—Superheated Steam.
Bulletin No. 31—The Thermal Conductivities of Alloys.
Bulletin No. 34—Effect of Stratification of Furnace Gases on Steam Boiler Losses.

Purdue University

Bulletin No. *1—Flow of Water Through One and One-half Inch Pipe and Valves. 1918.
Bulletin No. 8—Flow of Water Through Spiral Riveted Steel Pipe. 1921.
Bulletin No. 25—Flow of Heat in Pistons. 1925.

University of Washington

Bulletin No. 34—Centrifugal Fans: Performance, Characteristics and Methods of Testing. 1926.
Bulletin No. 45—Loss of Head in Three Types of Water Meters. 1927.
Bulletin No. 46—The Float-and-sink Testing of Fine-Size Coal. 1928.

Pennsylvania State College

Bulletin No. *14—Purchasing Coal by Specification and Methods of Sampling. 1914.
Bulletin No. *21—Empirical Method for Determining the Ultimate from the Proximate Analysis of Coal. 1915.
Bulletin No. *27—The Relative Corrosion of Alloys, 1918.
Bulletin No. 32—Heat Transmission and Efficiency in Steam Boiler Tubes. 1924.

Welding

Until ten or twelve years ago welding was employed principally to repair broken parts of machinery and other metal parts. Today it is accepted by industry as a most important production as well as repair process.

The rapidity with which the welding art developed during the World War was responsible for some unsatisfactory work and consequent delay in the general acceptance of the process. With a realization of the need of standardization for the orderly and conservative development of the several welding methods, the American Welding Society was formed in 1919 for the broad purpose of putting the welding art on a sound, scientific and engineering basis.

The American Welding Society is an organization of individuals and also companies and corporations interested in welding by any process—either as manufacturers of welding equipment and supplies interested in the commercial acceptance of the art, or as users concerned with its efficient application.

The research department of the American Welding Society is known as the American Bureau of Welding. This Bureau acts also as the Welding Research Department of the National Research Council and in addition to representatives from the Society, includes representatives from some twenty other interested scientific and engineering bodies. The Bureau maintains a technical information service and is recognized as an authentic source of welding information.

The American Welding Society, at the request of the A. S. M. E. Boiler Code Committee, is now preparing a general procedure, governing the use of welding in the construction of unfired pressure vessels, which can be used in connection with, or be made a part of, the A. S. M. E. Code for Unfired Pressure Vessels. A joint research committee on pressure vessels has also been organized under the auspices of the American Society of Mechanical Engineers and the American Bureau of Welding. This committee includes representatives from both sponsor organizations, as well as from other interested scientific and engineering societies, from interested welding apparatus manufacturing companies and also from tank manufacturers.

Under the auspices of the American Standards Association there is being prepared a comprehensive code dealing with pressure piping, the American Society of Mechanical Engineers acting as sponsor body. That section of this code which will deal with the use of welding in such work, is being formulated by the American Welding Society. The Society has also appointed a committee to prepare standard nomenclature, definitions and symbols in the welding field.

---

*Not available for general distribution.

The principal publication of the American Welding Society is its monthly *Journal* distributed free to members and for sale to the general public. The Journal contains papers giving accurate information on the application of welding in a wide variety of fields, as well as research committee reports and other matter pertaining to the welding art.

Aside from the *Journal,* the Society publishes from time to time bulletins containing reports of its research department, the American Bureau of Welding. A list of these bulletins, as well as of reports and papers dealing with various phases of welding, is included in the August number of the *Journal* which is issued each year as a Year Book. Information regarding the Society or its publications may be obtained by addressing the American Welding Society, 33 West Thirty-ninth Street, New York, N. Y.

A list of some of the American Welding Society's publications of interest in connection with mechanical power plant equipment is appended. References to the "Journal" refer to the *Journal* of the American Welding Society.

TREATMENT OF FEED WATER

The Treatment of Feed Water Subcommittee has made a survey of the central station field to determine the general practice in regard to the treatment of boiler feed water and the results obtained by the various methods. Forty statements have been received from operating companies, showing that twenty-four use evaporators, nine chemical treatment, three zeolite and four no treatment at all. Included in these statements is one from an operating company that uses evaporators in all its high pressure plants, and another from an operating company that uses zeolite softeners; the latter company operates for the most part relatively small sized low pressure generating stations.

Evaporators

Of the twenty-four plants using evaporators, ten pre-treat the evaporator feed. Of these ten, six use zeolite softeners, while one employs a unit system of evaporators and has a zeolite softener installed ahead of only one of the four units.

One of the plants reports that in the past it used zeolite softeners on the evaporator feed, but has discontinued this practice, and now feeds raw water to the evaporators.

Four plants reported the use of a chemical treatment of the water before going to the evaporators; two, the treatment of harbor or river water with alum and caustic soda as a coagulative, another the use of a "Scaife," lime-soda system, and the fourth a lime, iron sulphate, and barium hydrate treatment.

Nine of the plants using evaporators treat the entire boiler feed water before it enters the boilers, that is the condensate plus the make-up water, stating that it is necessary to add sodium phosphate and soda ash to maintain positive alkalinity. Some of these plants add caustic soda when the boilers are being refilled, and others make weekly tests from every boiler in order to control the sulphate-carbonate ratio and thus prevent embrittlement. One of these plants also reports using Glauber salts.

Two of the plants treat only the evaporator distillate in order to produce the desired alkalinity.

Three of the companies using additional chemical treatment report having difficulty with scaled superheaters, or deposits in the turbine blading when using chemicals in boiler feed water treatment.

The replies from the various companies indicate that the treatment of the make-up water to the evaporators is beneficial in a great many cases where the evaporator feed has properties producing very hard scale, and that the difficulties encountered due to the introduction of treatment of the water are of minor consequence if properly supervised. The same is true where treatment is used to produce positive alkalinity.

The results of the evaporator performance of four of the plants are given by tests which show the solids in the distillate from evaporators. Only one of the reporting companies submits data giving the moisture contained in the evaporated vapor.

Chemical Treatment

Chemical treatment is being used in nine of the plants, in most of which the boiler feed contains only a small amount of scale-forming matter, so that only a small amount of treatment is necessary. One of the plants reports considerable deposits in the superheater and turbine blading; this deposit is removed by washing. Another plant reporting difficulties on account of the carry-over of treatment chemicals states that the problem was solved by the installation of steam purifiers in the boiler drums to remove impurities in the steam, and by employing continuous blow-down, which is an aid in the control of the treatment.

Zeolite Treatment

Two plants of one company using zeolite treatment report generally satisfactory results. One of the plants reports difficulty with a mud deposit on the tanks and zeolite, which is not removed by back washing. Another plant reports difficulty through formation of channels in the zeolite, and that if water velocities are increased to agitate the zeolite the material is carried over.

Corrosion of Non-Ferrous Metals

Several of the companies report the occurrence of corrosion in bleeder heaters and evaporator condensers. Except for the evaporator condensers, the method of treatment seems to bear no relation to corrosion. In all cases corrosion has been remedied by the additional deaeration of the water and venting of the equipment. One company reports that corrosion of the tubes in its evaporator condensers has been corrected by the installation of an open heater on the evaporator feed in order to reduce the amount of gases that would otherwise be discharged to the evaporator condenser.

OPERATING COMPANIES' STATEMENTS

STATEMENT BY THE KANSAS CITY POWER & LIGHT COMPANY, KANSAS CITY, MO.

Northeast Station

"To date, boiler feed makeup for this station has not been treated, since city water has been used, and the estimated saving did not warrant the investment in a treating system. However, as the new 1200 lb. boilers will operate on condensate only, the per cent makeup to the 300 lb. boilers will be increased to a point where it is deemed advisable to treat.

"A Cochrane hot process lime and soda system of 50,000 lb. per hr. capacity is being installed and will be ready for service when the 1200 lb. unit is started."

Publication No. 289-53, Serial Report, Prime Movers Committee.

Grand Avenue Station

"This station is being remodeled from a 185 lb. plant to a 600-185 lb. plant, and in addition to supplying electrical energy, will also supply the commercial heating system steam. As the condensate from the heating system is not returned, the makeup, particularly in winter, will run very high.

"A two unit Cochrane hot process lime and soda system of 470,000 lb. per hr. total capacity is being installed for treatment of the makeup, and provisions are also being made for treatment with tri-sodium phosphate.

"This equipment will go in service about Jan. 1, 1929, when the new 600 lb. unit is started."

STATEMENT BY THE PENNSYLVANIA-OHIO POWER & LIGHT COMPANY

Toronto Plant

"The amount of makeup water varies from 1.5 to 2.0 per cent of the total boiler feed.

"Condenser leakage is kept at a minimum by testing the condensate daily and closing all leaks as soon as practical. The bacteria method of testing for leakage is used. Samples are collected from the condenser hot wells in sterilized bottles. A covered sterilized petri-dish containing 10 c.c. of nutrient agar is inoculated with 1 c.c. of the sample through a sterilized pipette. The corresponding plate is placed in an incubator at 37.5 deg. cent. for 24 hours. The number of bacteria colonies is then compared with the number of colonies for the raw water test to obtain the ratio of leakage.

"The makeup water is supplied by evaporators, whose output is vapor at 2 to 3 lb. gage pressure, and is discharged to the deaerators.

"The evaporators for the first two plant units are the film type, single effect, with 460 sq. ft. of surface and a maximum capacity of 12,000 lb. per hr. Those for the next two plant units are the submerged coil, Weir type, single effect, with 300 sq. ft. of surface and a maximum capacity of 12,000 lb. per hr.

"Ohio River water treated with lime and alum to remove suspended, organic matter and bacteria, is fed to evaporators 1, 3 and 4, but the water for unit No. 2 is also treated by a Permutit water softener.

"The average output of evaporators 1, 3 and 4 is 5500 to 6500 lb. per hr., whereas unit No. 2 delivers about 7500 lb. per hr.

"Evaporators 1, 3 and 4 are 'cracked' with cold water every day and manually cleaned every 6 to 8 weeks, requiring about twenty-seven man hours for each cleaning. Unit No. 2 does not require these cleaning methods.

"Moisture in the evaporator output has not been determined, but the following data shows the mineral constituents of the condensed evaporator steam output in parts per million.

Evaporator Number	Silicon Dioxide	Iron and Aluminum Oxide	Calcium Oxide	Magnesium Oxide	Sodium Oxide	Ignited Sulphates
1	5.6	0.4	4.7	less than 0.1	1.4	20.0
2*	1.6	1.3	1.6	less than 0.1	1.0	8.0
3	3.2	0.7	0.5	less than 0.1	1.8	8.0

*Evaporator feed through a Permutit softener.

An average analysis of Ohio River water after being treated for sanitary purposes is as follows:

Silicon Dioxide	11.6 p.p.m.
Iron and Aluminum Oxide	6.8
Calcium Oxide	32.8
Magnesium Oxide	0.5
Chloride	7.0
Sulphur Trioxide	78.0

Sodium oxide and carbonate not determined.

"Due possibly to the amount of dissociation of water encountered at the saturation temperature (about 440 deg. fahr.), it is necessary to treat the water chemically to prevent corrosion. Samples of water from the blow-off line of the boiler mud drums are taken in an open container daily through a cooling coil at light loads and transferred to an Erlenmeyer flask and corked. This water is titrated for phenolphthalein and methyl-orange alkalinities and the pH value is determined by using La Motte color tubes. When the phenolphthalein alkalinity is below 25 p.p.m. or the pH value is below 8.8, enough soda ash is added to the boiler water to bring it to this point. Under normal conditions one pound of soda ash will increase the alkalinity 6 p.p.m., but sometimes under unusual conditions of makeup water, a greater proportion of soda ash must be added to obtain the desired result.

"Glauber's salts are also added to the boiler water to keep the ratio of sodium sulphate to sodium carbonate above 3.5 in order to prevent caustic embrittlement. The concentration of sodium sulphate remains quite constant, and it is only necessary to make weekly tests. This is done by precipitating the SO_4 ion from the boiler water with barium chloride solution.

"Salts for internal treatment are pumped into the boilers through the water columns.

"For 8 months this year an average of 66.2 lb. of Glauber's salts and 11.6 lb. of soda ash have been added per boiler per month. During this period the boilers have averaged 7.7 k. B.t.u. per sq. ft. per hr., and during the daytime operation 10.1 k. B.t.u. per sq. ft. per hr. The average evaporation per boiler per month was 110,000,000 lb.

"Due to the low concentration of solids in the boiler water (about 200 p.p.m. total solids) it is not necessary to blow down. Due to troubles not associated with water quality or treatment, the boiler water has been changed about every 3 or 4 months, and as these troubles are eliminated this changing will probably be at longer intervals.

"The boiler feed water contains an average of 4.5 p.p.m. total solids.

"No tubes have been lost due to scale or water treatment methods since the method described has been followed. A number of water screen tubes have failed, but as these failures occurred at points on the tubes subjected at times to flame impingement and as the tubes showed no evidence of scale at the time of failure, these losses were not ascribed to boiler feed water or its treatment.

"The first pass and the water screen tubes are turbined every 6 months and the others once a year.

"For about three months one boiler was treated with tri-sodium phosphate. After this period the boiler had to be taken out of service due to failure of superheater tubes. All of the superheater tubes were coated with a thick scale which analysis showed to be mainly silica dioxide, iron oxide and aluminum oxide and no alkali. In spite of this analysis, this trouble was ascribed to solids carried over with the wet steam caused by the use of tri-sodium phosphate since this was the only boiler so treated, and no scale was ever found in the superheater tubes of the other boilers."

STATEMENT BY THE UNION GAS & ELECTRIC COMPANY, CINCINNATI, OHIO

"The Columbia Power Station has been in operation since November, 1925, and all makeup water for this station has been Ohio River water treated with lime and soda ash, with ferrous sulphate as a coagulant, in a cold intermittent water softener. The boilers in this station operate at a drum pressure of 630 lb. gage and a final steam temperature of 725 deg. fahr.

"Six of the boilers are operated at an average rating of 7.7 k. B.t.u. per sq. ft. per hr., and the feed water treatment has been entirely satisfactory for these boilers with regard to scale formation.

"Two boilers are used to screen the reheat coils, and these boilers operate at an average rating of 15 k. B.t.u. per sq. ft. per hr. We have encountered some troubles with scale in these units.

"With this method of feed water treatment it has not been possible to maintain the ratio of sodium sulphate to sodium carbonate recommended to prevent caustic embrittlement.

"Early in the year 1928 we added disodium phosphate continuously to the condenser hot wells in sufficient quantity to maintain a phosphate concentration of 50 p.p.m. in the boiler water. The boiler blow down was also regulated so that the total solids in the boiler water did not exceed 1000 p.p.m.

"This phosphate treatment has been very successful in eliminating scale even in the boilers operating at 15 k. B.t.u. per sq. ft. per hr. average rating. The nature of the boiler water is such that caustic embrittlement is also inhibited.

"A similar system of feed water treatment is used at our West End Station where the boilers are operated at an average rating of 7.3 k. B.t.u. per sq. ft. per hr. at drum pressures of 260 lb. gage and a final steam temperature of 600 deg. fahr. The results of this treatment have been very satisfactory.

"At Columbia Station there has been some difficulty with deposits on the high pressure turbine blading which has reduced the capacity of the units about 10 per cent after a month's operation. An analysis of this deposit shows the following:

	Per cent
Sodium Hydroxide	35.33
Sodium Carbonate	29.95
Sodium Chloride	25.03
Sodium Sulphate	3.30
Magnesium Carbonate	1.28
Calcium Carbonate	1.64
	92.53

"It has been found possible to remove this deposit by passing a small amount of saturated steam through the unit when it is shut down. No deposits have been found in the superheater tubes."

STATEMENT BY THE COMMONWEALTH EDISON CO., CHICAGO, ILL.

"In the 1927-28 Serial Report of this subcommittee (N. E. L. A. Publication No. 278-81) results of tests on the operation of a Wheeler, four effect evaporator were given. The results at that time showed excessive carry-over from the fourth effect.

"To remedy this condition and also to obtain a higher capacity from the evaporator, a second fourth effect was installed, which operates in parallel with the original fourth effect. The vapor from the third effect was thus approximately divided in half, which meant that the vapor velocities leaving the two fourth effects would be correspondingly reduced.

"At first this evaporator was operated with zeolite treated water and later changed to raw filtered water, with the idea that successful operation could be accomplished without the expense of pre-treatment. During the last six months the operation has been entirely with raw water. The resulting scale is removed mostly by routine cracking down, and at this time no deleterious effects have been noted as a result of this practice, which is not in accordance with the original intentions. Cracking down, however, does not entirely prevent the formation of hard scale on the tubes and trays, which means that about every two months it is desirable to open up the effects and auxiliary condenser for more thorough cleaning.

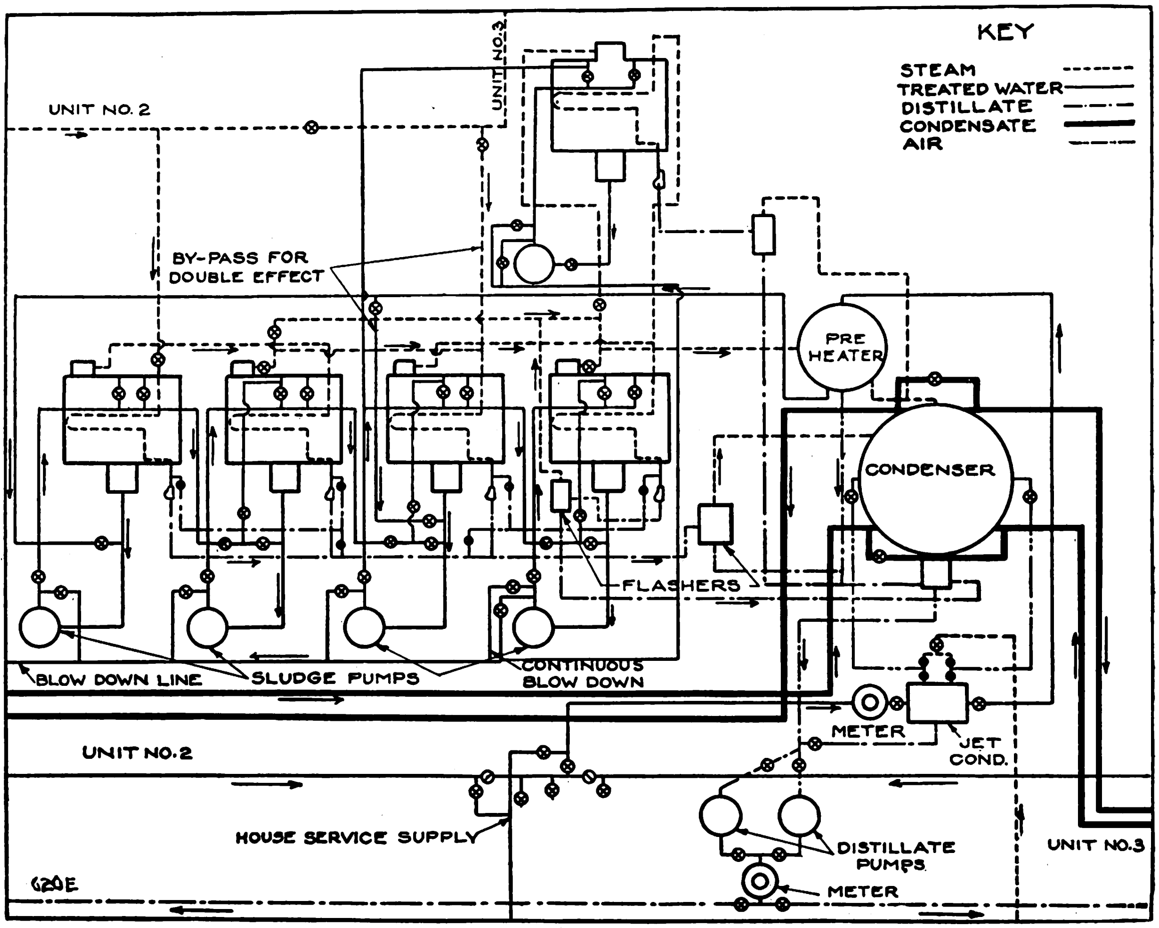

FIG. 1—EVAPORATOR PIPING—CRAWFORD AVENUE PLANT.

TABLE I

WATER ANALYSIS—TEST NO. 14—FOSTER-WHEELER EVAPORATOR—CRAWFORD AVENUE STATION OCTOBER 25, 1928

	P.p.m.	
	Filtered River Water Permutit Treated	Distillate Final Effect
Siliceous matter, SiO_2	0.51	trace
Oxide of iron and alumina ($Fe_2O_3 \div Al_2O_3$)	1.37	0.17
Sodium chloride, NaCl	40.90	1.54
Sodium sulphate, Na_2SO_4	39.85	1.54
Sodium bicarbonate, $NaHCO_3$	118.50	0.51
Calcium carbonate, $CaCO_3$*	0.34	0.34
Magnesium carbonate, $MgCO_3$†	0.34	0.17
Organic and volatile	22.60	1.37
Total solids	224.41	5.64
*Exists in the water as bicarbonate, $Ca(HCO_3)_2$	0.51	0.51
†Exists in the water as bicarbonate, $Mg(HCO_3)_2$	0.51	0.34

"The results of two tests on this equipment are given, one using Zeolite treated water and one using raw filtered water. Considerable improvement appears in the quality of the product over that obtained from the original installation. Although the evaporator effects were cleaned previous to tests, no particular increase in capacity was obtained, due probably to scale formation on the evaporating surfaces between cracking down operations.

"The second evaporator installation at Crawford Avenue Station is a Griscom-Russell single effect integral with the heat cycle of turbine No. 5 as indicated in Fig. 2. The manufacturer rates the equipment as having a normal capacity to evaporate 31,000 lb. of raw water per hr. when supplied with steam at 48 lb. per sq. in. abs. pressure and a maximum capacity of 44,600 lb. of raw water when supplied with steam at 76.5 lb. per sq. in. abs.

"This evaporator is of the bent tube submerged type, two evaporator shells and one evaporator condenser. Steam is supplied from the second I.P. bleed point (High Pressure element exhaust). The drainage is led to drainage of the second I.P. bleeder heater and flashed down in the first I.P. bleeder heater. The evaporated water is passed to the auxiliary condenser and returned to the main condensate line.

*Exists in the water as bicarbonate $Ca(HCO_3)_2$	113.1	....	18.65
†Exists in the water as bicarbonate $Mg(HCO_3)_2$	71.20	6.00	71.20

"For the past six months this evaporator has been operated with raw filtered water without deleterious effect. Some difficulty has been encountered in removing cracked scale, due to inadequate blow down arrangement. Larger and independent blow downs are expected to remedy this situation.

"Two raw water tests were run on this equipment with the results and averages as shown in Tables IV and V.

"The capacity of this system is at present limited in normal operation by the temperature of the returned distillate. As this distillate is returned to the main condensate line before the boiler feed pump, too high a temperature, occasioned by operating at too high shell pressures, would cause flashing at the pump suction.

"This evaporator is cracked down every 48 hr.

Conclusions

"The operation of both types of evaporators with raw untreated water for the past six months indicates that this practice under our conditions is quite practical. It means, however, that some cleaning program other than the routine cracking down is necessary to maintain the desired evaporator capacities. It is the intention to install sufficient evaporator capacity at the Crawford Avenue Station to satisfy the whole station makeup, which at present is not the case. The transition from one method of feed water treatment to another is largely the result of a desire to eliminate as much chemical treatment as possible, provided this can be done without deleterious effects."

STATEMENT BY THE DETROIT EDISON CO., DETROIT, MICH.

Beacon Street Heating Plant

"The zeolite system installed in this plant was fully described in a paper entitled 'Zeolite Water Treatment in a Large Central Heating Plant,' by Messrs. White, Walker, Partridge and Collins, presented at the 1927 convention of the American Waterworks Association. At that time the system had been in use only a few months, and consequently but little operating experience had been accumulated. However, the system has continued to give generally satisfactory performance, and due to its simplicity only a moderate amount of attendance is required.

"The acid treatment has successfully maintained safe conditions as regards caustic embrittlement. Some trouble has been experienced with the lead pumps handling the dilute acid mixture (a 4.5 per cent solution of sulphuric and a 0.5 per cent solution of phosphoric acids) and apparently some replacements of parts will always be necessary.

"The boilers have been operated at high steaming rates with no scale formation. Trouble has been experienced with corrosion which we attribute to the low pH value of the water occasioned by the presence of a considerable amount of $NaHCO_3$ and some CA_2. There is also a varying amount of oxygen present. This corrosion began immediately above the bed of zeolite and was evidenced in the cold and hot boiler feed piping, feed water heater, and, to some extent, in the boilers. It appeared as blisters containing green ferrous carbonate, which upon oxidation was changed to ferric oxide. A shallow pit would be found under each blister.

"This trouble has recently been successfully overcome by several different expedients applied to different parts of the system. In the cold water tanks and pipes protective coatings of several kinds have been tried with apparent success, although it is too early to make any definite statement. Cement lined pipe and pipe coated internally with bitumastic paint is being tried. In the feed water heater experiments with cadmium plating of the trays are giving promise of good results.

"Corrosion in the hot boiler feed lines and in the boilers has, we believe, been eliminated by the simple expedient of recirculating sufficient blow-off water back into the water space of the heater. This water, obviously, is rather highly caustic, hence all the free carbon dioxide in the initial water is converted into sodium carbonate, and the sodium bicarbonate is also converted to sodium carbonate, thus making the water sufficiently alkaline that it is non-corrosive to the metal.

"The small amount of phosphoric acid, about six p.p.m. of water treated, is added in order to precipitate any calcium present as calcium phosphate, which forms a thin coating on the boiler metal and helps, we believe, to inhibit corrosion. Some calcium is always present (about one or two p.p.m.) because of its non-removal by the zeolite.

"Two protective coatings, Nitrose and Apexior, have been used and are apparently successful in producing a rather permanent protective coating in the drums. It is felt, however, that the recirculation of the blow-off water is adequate to prevent further corrosion in the boilers and hot pipe lines. This experience emphasizes the fact that, with water containing considerable sodium bicarbonate and free carbon dioxide, corrosion is likely to occur even though the O_2 content is exceedingly low.

"The zeolite system operates on automatic control, and the engineer in charge is warned by an electric signal when a filter bed has softened a predetermined amount of water.

"The Leeds & Northrup conductivity meter, which records the conductivity (and, therefore, the corresponding concentration) of the blow-off water from each boiler, has given considerable trouble due to the short life of the water cells, but a new design of cell recently obtained may be an improvement. The hydrogen ion recorder, which was intended to show the pH value of the acidified water and of the water entering the boiler is not at the present time regarded as a suitable operating instrument."

MANUFACTURERS' STATEMENTS

STATEMENT BY THE ELECTRO-CHEMICAL ENGINEERING CORP., CHICAGO, ILL.

"The Electro-Chemical Polarization Process for preventing corrosion in steam boilers, feed water heaters, condensers, etc., utilizes an electric current of low voltage, which is passed through the water as an electrolyte from submerged anodes that are insulated from the metallic portion of the boiler or appurtenances. The current used is approximately two to three milliamperes per sq. ft. of protected surfaces, the source being a two or three volt direct current.

"An arsenical compound is added to the water at definite periods, depending upon the nature of the service, and this is plated out on the heating surfaces. The object of this arsenic plating is to effect polarization of the cathodic boiler metal, which is accomplished because of the high discharge potential of hydrogen upon arsenic. Depolarization of this hydrogen film by the oxygen dissolved in the boiler feed water is prevented by constantly plating out an excess of nascent hydrogen by means of the imposed electric current passed from the anodes.

"This combination has proved very successful in stopping corrosion in locomotive boilers in various parts of the country. Definite, effective results have been reported as being realized in locomotives operating on very corrosive waters from Texas to Montana and Maine, indicating that the nature of the water does not alter the effectiveness of the method. Several installations applied to locomotive boilers using corrosive waters that ordinarily destroy the boiler material within the normal shopping period have been permitted to pass through the shops without requiring the usual renewal of materials. Indications are that this cycle will be duplicated at the next shopping of such locomotives. Great savings are manifested with this kind of performance. We believe that the future of this method of corrosion prevention is very promising."

STATEMENT BY THE NATIONAL ALUMINATE CORP., CHICAGO, ILL.

"One of the most recent developments in the treatment of water for boiler feed is the use of K.W.S. sodium aluminate. It has been repeatedly demonstrated in the past few years that the use of this alkaline coagulant has a number of distinct advantages:

1. In chemical water softeners to replace acid coagulants, such as ferrous sulphate or aluminum sulphate.
2. For use as a coagulant for internal treatment of boilers or evaporators.
3. For pre-softening and clarification preceding Zeolite.
4. For use in conjunction with acid coagulants for electrification only.

"One of the chief difficulties in the proper operation of chemical water softeners is the complete removal of the finely divided suspended matter thrown out of solution by the lime and soda ash treatment. Such material frequently must be removed by filters, and in fact at times is only partially removed by this medium. It has become quite general practice, therefore, to use some form of coagulant in conjunction with lime and soda ash to precipitate such matter in the settling tank itself, thus better preserving the filter medium, saving wash water, and minimizing the possibility of such matter passing through the filter. The disadvantage of other coagulants for this purpose is that they react with the lime and give calcium sulphate as part of their reaction. This must be softened with soda ash, and gives as a result excess sodium sulphate which in turn increases the total solids in the boiler feed.

"With sodium aluminate the reaction takes place best with the magnesium in the water, giving magnesium aluminate, a very flocculent precipitate. Thus coagulation is obtained by direct reaction of the coagulant on the natural incrusting salts in the water, rather than requiring additional softening chemicals for reaction. Thus essentially, no excess soluble salts are formed due to the use of sodium aluminate.

"On certain turbid waters under 171 p.p.m. of hardness this has permitted a reduction of as high as 40 per cent in blow down requirement. In addition to its coagulating properties, however, even more important advantages are found in the speed of reaction of sodium aluminate. This permits of faster softening reaction, which increases plant capacity and produces a more stable resultant water, practically eliminating after reaction. This is due chiefly to its powerful and definite reaction on magnesium salts. Generally it is possible to produce a water of lower hardness with less excess treatment, or if need be produce a water which can be handled without difficulty with higher excess treatment.

"For internal treatment in a boiler or evaporator, the chief advantage of the use of sodium aluminate is in its coagulating power. Of course, the softening power is of distinct advantage also, but its chief function is to coagulate the finely divided particles thrown out by chemicals and heat, and thus inhibit scale formation and carry-over.

"For economical reasons it is generally advisable to use auxiliary softening reagents, such as soda ash, to finish the softening reactions. Only sufficient sodium aluminate is used to obtain proper coagulation. With this use of sodium aluminate it is, of course, just as necessary to check boiler water analysis as it is to check that of water from softening plant equipment, and special equipment and methods to check boiler water hardness, alkalinities, concentration, and for sulphate to total alkalinity ratio for prevention of embrittlement, have been designed for this purpose. Such equipment and methods are especially adapted to power plant use so that both the method and equipment are simple enough, so that power plant operators will not have to be chemists to understand the fundamental principles involved. With this method control is sufficiently positive, and results are, therefore, more nearly assured. Little time is required for such tests.

"For pre-treatment of water preceding zeolite, sodium aluminate in conjunction with lime, or with lime and soda ash, will give a clear water of lower total alkalinity, and with lower phosphate alkalinity or causticity reading. This is desirable to prevent incrustation of zeolite mineral.

"In straight water clarification (filtration), it is found that with the use of a very small amount of sodium aluminate in conjunction with an acid coagulant, subsidence is much faster and reaction is more positive, independent of the condition of the water itself. Also on waters of low pH value, coagulation can be obtained with a higher resultant pH and with lower CO_2 content, as compared to the use of an acid coagulant alone."

STATEMENT BY THE PERMUTIT CO., NEW YORK, N. Y.

Zeolite Softeners

"A few of the larger high pressure installations of zeolite softeners that have been contracted for during 1928, are given in Table VIII.

"A saving is obtained in operating costs (for chemicals) by using zeolite treatment, due to the fact that salt to regenerate zeolite in many localities is less expensive than the soda ash required to treat the same water. The city of Sewickley, Pa., is now installing a zeolite plant to treat 690,000 lb. per hr. Several power plants with existing hot or cold lime soda plants have replaced them with zeolite because of the improved quality of the effluent and lower operating costs.

Natural Brine and Sea Water Used for Regeneration

"Progress has been made in utilizing natural brines or sea water to regenerate zeolite. After considerable experimentation, the effects of the calcium and magnesium impurities in such natural brines on the capacity of the zeolite, and on the manner of applying regeneration, have been determined. Several large zeolite plants, two of which soften 34,700 and 52,000 lb. per hr., respectively, are successfully using sea water for this purpose, while one plant of 173,000 lb. per hr. capacity successfully uses natural brine from wells. Central power plants, located where natural brine wells are in existence or where sea water is available, should investigate this possibility because treatment is thereby obtained without any cost for chemicals, and only the fixed charges on the investment are left.

Zeolite Plants Preceding or Replacing Evaporators

"In some cases the difficulties and costs of scale removal, and heat losses by radiation and blow down of evaporators, have been reduced by installing zeolite ahead of the evaporators and using a continuous blow-off arrangement. This has eliminated scale problems and part of the losses of heat by blow-off. It is noteworthy that two transatlantic liners, the *Aquitania* and *Majestic,* have recently announced

their discontinuance of evaporators and the installation of zeolite plants to treat the fresh water make-up which they carry in their tanks from port to port.

"Distilled water, even if oxygen free, may be corrosive, because when it is heated to boiler pressure and temperature, its pH value decreases appreciably. This requires the addition of alkali. Furthermore, condenser leakage frequently introduces scale-forming constituents into the boiler feed water, and for this reason alkali is usually added. For practice in the addition of this alkali, see the Navy Department 1922 Manual of Engineering Instructions, Chapter 6, and for the usual stationary practice, see *Power,* June 9, 1925, page 899. If alkali is added to the feed water, in order to overcome its acidity at high temperatures and to counteract scale-forming constituents from condenser leakage, then it also may become necessary to add sulphates if the so-called sulphate-carbonate ratio is to be maintained. After this treatment the final feed water is not superior to zeolite softened water, which usually contains natural alkalinity to take care of these conditions. Boilers fed with condensate from leaky condensers and distilled make-up water must be blown down to remove the hardness-forming constituents introduced through the condenser leaks. Heat losses will result if the heat of the blow-off water is not recovered, but if apparatus for recovering this heat is installed, the same apparatus can recover all the heat in the blow-off water in the event that the make-up water is derived from a zeolite softener instead of an evaporator.

"It is difficult to blow-off intermittently such amounts as will keep the concentration between certain limits and yet avoid excessive waste of heat. Intermittent blow-off is rapidly being abandoned, and continuous boiler blow-off is becoming recognized as the best practice, just as continuous feeding has replaced intermittent feeding. If continuous boiler blow-off is used, the only effect of evaporators is to reduce the amount of water thus continually blown off, and since the heat of this blow-off stream is recovered by heat exchangers, the greater economy of zeolite plus such continuous blow-off, as compared with evaporators, will become apparent.

Permutit Continuous Blow-Off Apparatus

"A number of power plants have contracted for such blow-off apparatus in 1928, among which may be mentioned those listed on Table IX, attached. We have designed an excess flow check valve, which closes as soon as the rate of flow exceeds the predetermined rate. This is a safety feature to prevent the boilers from emptying in case any of the pipe lines should fail.

"The rate of flow controller, see Fig. 4, is so designed that a constant depth of boiler salines (after cooling in the

heat exchanger) is maintained over an adjustable orifice. A specially designed high pressure float valve maintains a constant level. These float valves are in actual use, withstanding a boiler pressure of 450 lb. per sq. in. Because of the low depth in this box, the controlling orifice in its bottom is necessarily large. This avoids the difficulties which would be experienced with small orifices for the regulation of the rate of flow. The high pressure float valve is self-cleansing to a considerable extent, because if any small particles enter the ports when in a throttled position, a reduction in flow causes the level to drop in the box, which opens the ports of the float valve wider and allows the particles to come through. Furthermore, by controlling the rate of flow after the heat exchanger, the blow-off water does not flash into steam and these controllers can, therefore, be placed in any room without provision for the removal of the vapors that would otherwise rise from them. This permits easy inspection, and since each boiler has its own controller (see Col. 9 of Table IX), the operator can see at a glance which boilers are being blown off correctly.

Acid Feeds

"The danger which is sometimes feared with acid feeds, installed to provide a predetermined sulphate-carbonate ratio in the feed water, is the feeding of an excess of acid. We have developed a new type of acid feed which fulfills the following specifications:

1. If any part fails, it results in stopping the feeding of acid, and optical signals inform the operator.
2. The acid is stored and measured in concentrated form and is then automatically and continuously diluted in the apparatus itself on its way to the water to be treated. Accordingly, it occupies a minimum of space and does away with the process of intermittently diluting acid manually, which must be done slowly and carefully.
3. The feed water is measured by a meter in the supply pipe, and this meter actuates the acid pump through electrical and mechanical connections, in proportion to the actual amount of water fed. If no water passes into the boiler, then the meter does not move and cannot actuate the acid feed. In addition, optical signals then inform the operator of the condition of the apparatus. An installation of one of these feeds, handling 600,000 lb. per hr., is now being made, and is referred to with others, in Table X.

"In 1928 there came to our attention only two cases of boiler failure where zeolite treated water was used, and these were ascribed by others to so-called 'caustic embrittlement.' We had an opportunity to examine samples of the boiler material from both these cases. One was a boiler purchased second-hand during war times; the cracked drum was found to contain many rivet holes that did not match; signs of the use of drift-pins were in evidence, indentations under the rivet heads indicated the use of excessive riveting pressures, etc. Only one boiler failed in this plant out of a battery of four using the same water.

"In the other case a number of water tubes cracked circumferentially in certain rows of the boiler. It could not be explained why caustic soda should have concentrated in these rows.

"Metallurgical reports on samples of steel from the tubes showed that the steel was not above reproach. Furthermore, incipient cracks started on the fire side of the tubes, and only where the rolling in of the tubes had produced excessive deformations.

Continuous Blow-Off Plus Acid Feed

"This combination permits an added factor of safety against acid corrosion of feed lines and economizers. Part of the alkaline boiler blow-off water is continually added to the acid treated water after aeration or in the bottom of the heater. The acid reacting with the alkalinity forms CO_2. This is partially liberated in the aeration chamber installed with our acid feeds. The remaining CO_2 is then removed in the heater. The alkaline blow-off stream then enters the water and raises the pH value of the feed water to any desired limit. See Fig. 5.

Sodium Phosphate Feeds

"We have developed a simple phosphate feed where maintenance of a phosphate-carbonate ratio is desired instead of a sulphate-carbonate ratio. This feed has no moving parts, requires no pumps, and works hydraulically. See Fig. 6.

FIG. 6—PERMUTIT ACID FEEDER.

It operates as follows: the di- or tri-sodium phosphate is dissolved in the solution tank, and is then drained into the feeder pot. The glass float in the column attached to this pot floats in the solution but sinks in water, and, therefore, indicates the position of the top surface of the phosphate solution. When the contents of the pot have been used up, the float is low and indicates the need of recharging. The actual feeding is accomplished from the pot by displacement. Primary orifice 'A' causes a pressure drop in proportion to the flow, and forces some water through Primary Shunt Line 'P' and its return 'P'' thus creating a pressure drop across Secondary Orifice 'S.' This in turn forces water into the top of the pot, displacing the chemical solution which passes through 'P'' into the raw water. The design and location of the primary and secondary orifices and the proportioning of the pot and pipe sizes make it possible to feed the chemical in amounts that are always proportional to the rate of flow of the water to be treated."

OPERATING CODE MANUAL

The apparent need for a manual of this type, outlining rules of operating procedure in both the boiler and turbine rooms of steam-generating plants, has led the Prime Movers Committee to revise and republish in convenient form all of the previous reports of the Subcommittee on Operating Code Manual.

The rules contained in the previous reports were based on the comments and criticisms to questions contained in questionnaires drafted from rules extracted from the Station Operating Handbook of the Philadelphia Electric Company.

As it is impossible to formulate one set of rules to fit all cases, no attempt is made to stress adherence to the sequence of the different operations, it being understood that modifications are necessary, depending upon the best judgment of the particular problems and upon the installed equipment in each individual plant.

However, the use to which an operating code may be placed lies entirely in the hands of the individual engineers. It is very probable that in emergency cases such rules will of necessity be overstepped or entirely ignored, but their very existence and the familiarity of the operator with them for normal operation will cause them to serve as a guide and promote good judgment in cases of emergencies.

The value of a code of this kind is not measured by the exactness with which the rules embodied are carried out, but rests, rather, upon the fact that these rules in their general make-up include all possible necessary phases of any particular operation.

SECTION I—BOILER PLANT

A—GENERAL OPERATION

1—Boilers

In order to avoid duplication wherever possible, this part of the code covering the general operation of boilers has been so formulated as to apply both to stoker fired and to pulverized fuel fired boilers. To assist in fixing the application of a rule to the specific type of installation, the following nomenclature has been adopted: (1) Rules which apply to both stoker and pulverized fuel installations have no marking other than the number of the rule itself, such as "101," Rule 2. (2) Rules which apply solely to stoker fired boilers have the letter "S" following the rule number, such as "101," Rule 6-S. (3) Rules which apply solely to pulverized fuel fired boilers have the letter "P" following the rule number, such as "103-P."

The rules for stoker fired boilers have been drawn up particularly for underfeed stoker installations, but it should be readily apparent wherein these rules should be modified in particular cases to cover other types of stoker firing.

[Note: Blank spaces (......) to be filled in by plant engineers to suit their individual plant operation.]

100. Inspection Before Taking Over the Shift

At the beginning of each shift, before taking over the shift, the Water Tender or Boiler Operator must proceed as follows:

1. Blow down the water column and gage glass on each boiler and test the gages by opening the gage cocks to determine the water level.

This should be done by the Water Tender or Boiler Operator, but anyone else detailed may blow down duplicate columns under supervision of the Water Tender or Boiler Operator.

2. Observe fires, ratings and instruments; then judge if fuel feed is correct for maintaining same, or for correcting furnace conditions or ratings.

Attached to each boiler should be a chart of instructions developed for proper operations under normal conditions. If it is impossible to adhere to these instructions, the Boiler Engineer should be informed.

3. Examine the gage board to see that all instruments are in operation.

4. The Water Tender or Boiler Operator leaving the shift must report to his relief any unusual or special conditions pertaining to the apparatus and fires. Special attention must be given in this report to the condition of the automatic feed water regulators and hand operated feed water valves.

5. On taking over the shift, the Water Tender or Boiler Operator assumes full responsibility for further operation.

101. General Operation

1. After assuming responsibility for the shift, the Boiler Operator or Water Tender must not leave the boiler room floor under any consideration without notifying the Shift Superintendent or Boiler Engineer. In any event, the Water Tender or Boiler Operator is responsible for boilers assigned at all times and must not leave the floor in time of trouble or impending trouble.

2. Maintain about .... to .... gages of water in each boiler when steaming.

3. All boilers should be operated at or near the same rating, except when specific characteristics of individual boilers demand a departure from this rule.

4. Draft and fuel feed should be set, using instructions posted by supervisory force on bulletin board as a guide, altering them, if necessary, to suit existing conditions.

Publication No. 289-58. Serial Report, Prime Movers Committee.

5. Always maintain the draft over the fire as stated on the chart. Exception is made to this only for a short time before dumps in stoker fired stations having no means of putting air on the extension grates and in emergency cases.

6-S. All extension grate dampers should be opened according to the general instructions of the Boiler Engineer.

7. Fires should be inspected by the Water Tender or Boiler Operator from the front, side and rear doors from time to time, and when instruments indicate irregularities to determine their condition.

This should be done by the aid of colored glasses made for this purpose.

8-S. When dumping time approaches all fires must be inspected, and those fires which have unburned coal on the dump plates should, if possible, be burned down in the rear before dumping.

If there is so much coke on the dump plates that it is impossible to properly burn it down, this coke should, if possible, be winged back on the fire with a bar.

Where extension grates are installed, the rear of the fire may be burned down by opening the extension grate dampers. Where these are not installed, the rear boiler damper should be opened wider than usual.

9-S. Dump each fire as rapidly as possible, but allow sufficient time between boilers so that the steam pressure will not be affected.

10-S. With boilers equipped with clinker crushers, care must be taken to see that large clinkers do not form in such a position that they will not go through the rolls. This type of clinker should be hooked around with a bar so that its length is parallel with the clinker crusher.

The ash should be held in such amount as permits of best furnace operation.

11. Blow down the boiler from both the main and surface blow-off (when provided) according to the instructions of the Boiler Engineer.

The main blow down should be made with the boiler banked, if possible, or steaming capacity checked.

12. The blow-off valves of the economizers should be operated according to instructions of the Boiler Engineer.

13. The procedure in blowing down main blow-offs is as follows:

(1) Open plug cocks with lever wrench.
(2) Open main blow-off valves slowly.
(3) Close main blow-off valves slowly.
(4) Close plug cocks with lever wrench.

[NOTE: While blowing down, the Water Tender should watch the level of the water in the gage glass.]

14. The following items should be entered on the Boiler Room Log Sheet (Form ......) by the designated person.

(a) The number of hours each boiler was steaming, banked and out;
(b) The time of dumping;
(c) The number of hours the fans were in operation;
(d) The reading of the stoker counters at midnight;
(e) The amount of blow-down.

102-S. Putting a Boiler on the Line—Stoker Fired

1. Remove all danger or "Out of Service" signs placed on valves and equipment controls, and inspect all boiler setting doors to see that they are tightly closed.

2. See that blow-off valves are all closed. Where a safety stop gate valve is connected to the blow-off line, see that this valve is open.

3. Open all vent valves.

4. Close all drain valves.

5. See that valves controlling water column and pressure gages are in operating condition and open.

6. See that water column blow down valves are closed.

7. Open the water feed valves to the boilers slowly for one or two turns. (On boilers equipped with separate economizers, see that the valves between the boilers and economizers and economizer vents are open.)

8. Fill the boiler to about ....

9. Operate superheater drains according to instructions of Boiler Engineer.

10. Start the stoker and fill the grate about .... way down with coal.. This requires about .... revolutions of the stoker.

11. See that the change-over valve on the water back lines is set for raw water.

12. Open the feed and discharge valves on the water backs.

13. See that "tell tales" are open and discharging water, and that the drains are clear.

14. Open the stack damper to give about .... in. draft in furnace.

15. Dig holes in the coal over the tuyeres and put a shovelful of fire in each hole or use wood and oil-soaked waste.

16. Cover the fire with "green" coal and start stoker slowly.

17. When fire is hot enough to insure proper coking, start both the induced and forced draft fans slowly.

[NOTE: Have the electrician inspect the motor-driven forced and induced draft fans before starting.]

18. Adjust the stack damper to .... in. draft over the fire.

19. Apply .... in. blast on the forced draft.

20. Close all vents on the boiler as soon as total elimination of gas and air from boiler is insured.

21. Note that the pressure gage is operating.

22. Turn on the spray of the clinker crusher pit as soon as hot ash begins to accumulate.

23. Raise .... lb. pressure on the boiler, and unlock automatic non-return valve.

24. At .... lb. pressure, drain feed water regulator if it is of the thermostatic type.

25. Increase the speed of the fans, for both induced and forced draft, to such a degree as may be required.

26. Bring the boiler gage pressure gradually up to .... lb.

27. See that the drain valves between the main and automatic non-return valves are open.

28. Open the main stop valve by-pass valve and blow out all water from the line between the automatic non-return valve and the main stop valve.

29. Close the drain valves.

30. Open the trap line valve above the automatic non-return valve.

31. Open the main stop valve and close the by-pass on the same.

32. Increase the stoker speed and air blast until the boiler begins to steam. Keep the fire as light as possible.

The rate of increasing the blast and stoker speed is determined by how fast the boiler must be put on the line.

33. Set the change-over valve on the water back line for condensate.

34. Blow down water columns to check the water level and test safety valves when boiler is on line.

35. Cut in automatic boiler feed control.

103-P. Putting a Boiler on the Line—Pulverized Fuel

1. Proceed according to "102-S," Rules 1-9 inclusive.

2. Have coal in pulverized coal bunkers. (For unit system have coal in green coal bunkers, and pulverizing mill ready for operation.)

3. See that stack damper is open.

4. Start the induced draft fan slowly.

5. Start the primary air fans and adjust speed to give .... inches pressure.

6. Adjust the secondary air door opening and the induced draft fan speed to give .... in. furnace draft.

7. Light .... burners.

[NOTE: The following procedure in lighting burners is suggested.]

(1) Open the dampers (gates) above the coal feeder.
(2) Light the torch and insert it in the burner.
(3) Close the main switch on the feeder motor.
(4) Open the primary air damper on the feeder.
(5) Start the feeder motor by operating the push-button control.
(6) Throw in the feeder motor clutch.

8. Close all vents on the boiler as soon as total elimination of gas and air from the boiler is insured.

9. Note that the pressure gage is operating.

10. Add burners according to the individual plant schedule.

[NOTE: The rate at which burners are to be added is determined by the time allowed for putting the boiler on the line, giving due consideration to the extent of the furnace repairs which may have been made while the boiler was down.]

11. Proceed according to "102-S," Rules 23-30 inclusive, until the boiler is on the line.

12. Proceed according to "102-S," Rules 32, 33 and 34.

104-S. Putting a Boiler on the Line from a Banked Condition—Stoker Fired

1. Blow down the water column and gage glass; test the gages by opening the gage cocks, and see that there is not over .... in. of water in the gage glass when putting a boiler on the line.

2. Open the superheater drains wide and allow them to remain open until superheater is thoroughly drained and the boiler is on the line.

3. Wing the ashes back on the clinker crusher, or drop the dump plates.

4. Close the dump plates.

5. Put the long stroke on the lower ram, where hand dump plates are used.

6. Shut off the draft on the extension grate.

7. Operate the water feed valves so as to maintain from .... to .... gages of water in the boiler, until the steaming rate is such that the feed water regulators will operate satisfactorily.

8. Open feed water valves wide.

[NOTE: With a short bank, it is not necessary to adhere to the above rules; however, it is necessary to maintain not more than one gage of water.]

105-P. Putting a Boiler on the Line from a Banked Condition—Pulverized Fuel

1. Blow down the water column and gage glass; test the gages by opening the gage cocks, and see that there is not over .... in. of water in the gage glass when putting a boiler on the line.

2. Open the superheater drains wide and allow them to remain open until the superheater is thoroughly drained and the boiler is on the line.

3. Start the induced and primary air fans.

4. Light .... burners, and add more burners according to individual plant schedule, until boiler goes on the line.

5. Operate the water feed valves so as to maintain from .... to .... gages of water in the boiler, until the steaming rate is such that the feed water regulators will operate satisfactorily.

6. Open the feed water valves wide.

106-S. Dumping

1. Cut off the forced draft.
2. Open the back dampers wide.
3. Stop or reduce speed of stoker.
4. Open the ash spray valve.
5. Dump the plates in sections.
6. Reduce the rate of water feed, if necessary.
7. Clean the fires, being careful not to throw good coal down with ashes.

(If there is much coke over the top of the clinker, close the dumps before hooking out the clinker.)

8. Raise the dump plates.
9. Adjust the forced and stack drafts for load.
10. Start the stoker.
11. Shut off the ash spray valve, after ashes are thoroughly wet.

107-S. Clinker Crushers

1. Operate the clinker crusher in accordance with the condition of the fire, by adjusting its operation to keep .... ft. of ashes over the crusher.

2. Inspect the clinker crushers at regular intervals for heating.

3. The crusher doors should be set to the proper opening by the Boiler Engineer when the boiler is off and should not be changed without his knowledge or the knowledge of the Water Tender or Boiler Operator.

Any change made in the opening must be sanctioned by the Boiler Engineer or Shift Superintendent.

4. The Boiler Engineer should make inspection at specified intervals.

108. Soot Blowers on Boilers and Economizers

1. Notify boiler operator that tubes are to be blown.

2. See that the drains on the soot blower supply manifold are open.

3. Crack the main steam valve and blow the water out of the manifold.

4. Close the drain.

5. Open the main steam valve wide.

6. Open the soot blowers in rotation, beginning with the first pass.

7. As the unit is being blown, rotate the blower slowly and steadily between the stops provided on the main wheel or on the hand wheel.

8. After blowing, close the main steam valve to the manifold.

9. Open the drain on the manifold and leave it open.

10. Notify boiler operator that blowing is completed.

109. Soot Blowers on Induced Draft Fans

1. The fan should be running at lowest speed when soot blowers are opened.

2. See rules 1, 2, 3, 4, 5, 8 and 10, of "108."

110-S. Clinkers on Side Walls

1. Bank the fires, if possible.

2. Wing the coal off the clinker with a scraper or bar.

3. Break the clinker from the side wall with a bar and clean the clinker off as far down as the grate.

Push the clinker to the rear of the fire, being careful not to mix green coal with clinkers.

111. High Water

1. Cut off the forced draft.

2. Stop the fuel feed.

3. Close the feed water valve.

4. Try the gage cocks to make sure that the water is high.

5. Open the superheater drains and surface blow-off valves, if easily accessible.

6. Open the blow-off valves and blow down water level to safe working conditions.

7. Partly close the back damper. Leave sufficient draft to clear the gases.

8. Maintain practically a banked condition and blow down until the water level has been lowered to between .... and .... gages.

9. If a feed water regulator is in service, close the feed valve to the regulator and operate the feed valve by hand until the trouble has been located.

10. When normal water level is reached, put the boiler in service similar to procedure in "104" or "105."

112. Low Water

FIRST OF ALL—Try to remedy cause. Then, if conditions become dangerous, proceed as follows:

1. Close the feed water valve to the boiler.

2. Cut off the forced draft.

3. Partly close the back damper, leaving sufficient draft to clear the gases.

4. Stop the fuel feed.

5. Where possible, drop the dump plates.

6. Drown the fire and allow the boiler to cool.

7. As the steam pressure drops below header pressure, shut the main stop valve.

8. Close the trap line valve above the automatic non-return valve.

9. Lock the automatic non-return valve.

10. After the boiler is cool, open all vents between automatic non-return valve and the boiler.

11. Inspect the boiler and subject it to a hydrostatic test.

113. Priming and Foaming

1. Close the feed valve.

2. Bank the boiler.

3. Open the surface blow-off valve and blow down until the water level is lowered about one gage.

4. Start as from a banked condition.

5. If foaming is not stopped by this method, shut down the boiler and wash it out.

114-S. Hot Stoker Rams—Upper Ram

1. Break the arch over the ram with air agitators or by hand, or, should there be an obstruction, dig the coal out of the hopper and remove it.

2. Feed green coal to the ram.

Lower Ram (Caused by Fire Being Too Thin)

1. Increase the stoker speed.

2. Reduce the drafts when possible.

3. Put the long stroke on the ram.

Lower Ram (Caused by Clinkers)

1. Put the long stroke on the ram, alternating with the normal stroke to break up the clinker.

2. Put U-pins on the end of the lower ram driving bar outside of the driving link to draw the ram farther out of the fire.

3. Dislodge the clinker with bars from the side doors.

4. Reduce the air blast, if it is possible to hold steam.

5. If this fails, take the boiler off the line and remove the clinker.

115-S. Holes in the Fire

1. Increase the stocker speed, cutting out the sections in which the fire may become too heavy.

2. Decrease the forced draft to light sections of the fire, if possible.

3. When a hole is near the front wall, open the extension damper in the section in which the hole occurs.

4. See that coal is feeding into the rams at which holes occur and, if it is not, use wooden rods to force the coal to the rams.

5. If a hole is in the rear, put on the long stroke and close the extension damper.

116. Broken Gage Glass

1. Close the upper and lower gage glass cut-off valves, the lower one first.

2. Open the gage glass free blow-off valve.

3. Replace the glass and washers.

4. Open the upper and lower gage glass cut-off valves, the upper one first.

5. Close the gage glass free blow-off valve.

All opening and closing of valves in this operation must be done from the floor level and the face must be shielded from a possible jet of steam or water or from broken glass.

117. Testing Safety Valves

1. All safety valves must be tested at specified intervals.

2. Pressure should be exerted upon the lever until the valve releases. If the valve sticks, or if too great a force is necessary to open it, it should be reported to the Boiler Engineer.

118-S. Breaking of Shear Pin on Stoker

1. Pull out the clutch on the section of the stoker in which the shear pin is broken.

2. Determine whether or not the speed shaft can be turned forward with an 18-in. pipe wrench.

3. If the shaft cannot be turned, find the obstruction and remove it.

4. Examine the stoker for damage.

5. Examine the bushing in the clutch and see that the cutting edge is sharp, that the face of the bushing is flush with the face of the clutch, and that the set screw is turned down to its lowest position in the groove and not binding.

6. Replace the shear pin and start the stoker again.

119. Shutting Down a Boiler for Banking

1. Cut off the forced draft.

2. Stop both the induced and forced draft fans.

3. Cut off the fuel feed. In case of a light stoker fire at the time of banking, let the stoker turn about .... revolutions to give a bed of green coal and repeat this operation approximately every hour during the banking period.

4. Close the damper of the stack draft until the opening is just sufficient to clear the furnace of gases.

5. Close the main feed water valve to the boiler.

120. Taking a Boiler Off the Line

1. Cut off the coal supply.

2. Set the change over valve on the water back line for raw water.

3. Run the coal feed pipes and hopper empty.

4. Cut off the fuel feed.

5. Shut off feed water valves, keeping the water in sight above the nut on the gage glass.

6-S. After the coal in the furnace is burned out, cut off all forced draft.

7-P. Shut off primary air fan.

8-S. Shut off the spray line in clinker crusher pit.

9. Stop both the induced and forced draft fans.

10. As the steam pressure drops, shut the main stop valve.

11. Close the trap line valve above the automatic non-return valve.

12. Lock the automatic non-return valve.

13. Open the vent valves on the superheater and open the drain valves between the main stop and automatic non-return valves.

14. Close the stack damper.

15. Shut off the water-back feed and discharge valves after the water-back soot chamber has been cleaned.

16. Empty the boiler through the blow-off valves when the setting has cooled.

The superheater drain valves on other boilers must be closed while this is being done.

17. When the boiler is empty, see that the safety stop valve in the blow-off line is closed and close all blow-off or guard valves and cocks.

18. Hang danger or "Out of Service" signs on the main stop, main feed, blow-off valves and control board.

2—Coal Handling Equipment

201. Crushers and Breakers—Starting

1. Lubricate.
2. See that the conveyor handling the crusher or breaker discharge is operating.
3. Start the motor drive.
4. Admit coal to the crusher or breaker.

Crushers and Breakers—Stopping

1. Stop the coal feed.
2. Run the crusher or breaker empty.
3. Stop the motor.
4. Close the lubricators.

202. Green Coal Conveyors—Starting

1. See that succeeding conveyors are operating and that bins are ready to receive coal.
2. Open lubricators where necessary.
3. See that current is on magnetic pulley.
4. Start motor drive.
5. Observe proper working of entire conveyor.
6. Admit coal into conveyor from source.

Green Coal Conveyors—Shutting Down

1. Stop coal feed.
2. Empty entire conveyor.
3. Stop motor.
4. Close lubricators.
5. Inspect for improper bearing, etc.

3—Pulverized Fuel Auxiliaries

301. Rotary Direct Fired Driers—Starting

1. Inspect drier for open doors, workmen or tools inside and general condition of equipment. Prepare torch for lighting fire.
2. Lubricate.
3. Start drier drive motor.
4. Start fan and adjust air flow.
5. Start coal feed and adjust same.
6. Light torch, put into furnace and start fuel feed.
7. Remove torch after combustion is well established.
8. Readjust air flow and coal feed to give desired moisture removal.

Rotary Direct Fired Driers—Shutting Down

1. Stop fuel feed to furnace.
2. After furnace cools, stop green coal flow.
3. Stop fan after drier is entirely empty.
4. Stop drier.
5. Stop lubrication.

302. Steam and Waste Gas Driers—Starting

1. Close off all air or flue gas dampers to driers out of service.
2. Open gates above driers and allow to fill with coal.
3. Cut in steam or flue gas slowly to driers about one-half hour before starting mills according to size of driers. Start drier exhauster fan at same time.
4. Put air washer, cyclone separators or other dust removal equipment in service on drier discharge air or flue gas.
5. Check traps for leakage on drains from steam driers.

Steam and Waste Gas Driers—Shutting Down

1. Shut off steam or flue gas to driers about one-half hour before shutting down mills or long enough to run all dried coal out of drier proper.
2. If mill is to be out of operation for more than 24 hours, empty drier before stopping mill.
3. Keep exhauster fan running until mills are shut down.
4. Shut down air washer, cyclone separator, etc., on drier outlet air or flue gas.

303. Pulverizing Mills (Central Bin and Feeder System)—Starting

1. Make general inspection of mill, including lubrication, making sure that sufficient oil is in reservoirs and that journal bearings are full of grease.
2. Open valve at bottom of collector.
3. Start pulverized coal transport system from collectors to bunkers.
4. Start mill exhauster fan.
5. Open slide in coal feed to mill.
6. Start mill, adjust to load.
7. Maintain uniform feed.

Pulverizing Mills (Central Bin and Feeder System)—Shutting Down

1. Stop coal feed by releasing clutch or throwing off feeder belt to allow mill to nearly empty itself of coal.
2. Stop mill.
3. Allow exhauster to continue running for two or three minutes after mill has been shut down, then shut down exhauster.
4. Close valve on base of collector.

304. Screw Conveyors—Starting

1. Make general inspection.
2. Lubricate.
3. Open valve at discharge from conveyor.
4. Start conveyor.

Screw Conveyors—Shutting Down

1. After making sure that no coal is entering conveyor, close valve to supply line.
2. Empty conveyor.
3. Stop motor.
4. Shut valve at discharge from conveyor.

305. Transport Pump—Starting

1. Start air compressor.
2. Make general inspection of bin above pump, transport line discharge, etc.
3. Check setting of switching valves.
4. Blow out transport line with compressed air, by sections if necessary.
5. Admit compressed air to pump.
6. Make general inspection of pump.
7. Lubricate.
8. Start driving motor.
9. Open gates above screw slowly.

Transport Pump—Shutting Down

1. Close gates above screw or completely empty hopper over pump.
2. Allow screw to empty.
3. Blow out lines.
4. Stop motor.
5. Stop lubrication.
6. Allow air to flow out of pipe, adding more compressed air if necessary.

306. Pulverized Fuel Bunkers—Before Conveying Coal to Bunkers

1. Inspect high and low bin signals or indicators for proper operation.
2. See that bunker vents are unrestricted.
3. See that no covers are loose or manholes uncovered.
4. If bunker is empty, inspect feeders to see that caps are on all clean-out holes and no openings around feeders.

307. Pulverized Fuel Bunkers—When Bunker Is to Be Taken Out of Service

1. If bunker is to be out of service for more than four days, all coal should be fed out.
2. Insert blank in coal supply line joint directly over bunker.
3. Clean out all feeders.

308. Feeders—Starting

1. Make general inspection.

2. Start lubrication.
3. Start primary air fans.
4. Adjust primary air to .... in. pressure.
5. Open the dampers (gates) above the feeder.
6. Insert lighted torch in the burner.
7. Close the main feeder motor switch.
8. Open the primary air damper on the feeder.
9. Start the feeder motor with the clutch out.
10. Throw in the feeder-motor clutch.

Feeders—Stopping

1. Close gate over feeder screw.
2. Stop feeder, after running the hopper empty.
3. Stop lubrication.
4. Close primary air damper.
5. Shut down primary air fan.
6. Open the main feeder switch.

309. Mills and Burners (Unit System)—Starting

1. Furnace operator should make a thorough inspection of mill.
2. Check for proper operation of magnetic separator.
3. Start lubrication.
4. Start mill with coal supply closed.
5. Regulate boiler damper or induced draft fan to give an under pressure in combustion chamber.
6. Light and insert ignition torch through port provided.
7. Start coal feed to mill at a rate determined by experience for best ignition.
8. Remove ignition torch as soon as burners are properly lighted.
9. Increase feeder speed as required.

Mills and Burners (Unit System)—Shuting Down

1. Stop coal feed to mill.
2. Allow all coal to run out of mill.
3. Stop mill.
4. Stop lubrication.

Precautions; Care and Maintenance

There are many precautions to be observed to insure the safe operation and proper care of coal pulverizing and preparation equipment. The National Fire Protection Association has prepared a set of regulations for the installation of pulverized fuel systems which will not be repeated in this report. These regulations also contain certain precautions to be observed in operation.

Following are suggested rules to be observed during operation and for the ordinary care and maintenance of the pulverizing equipment.

351. Conveying System

1. In case of transport line becoming plugged, blow air into line through each air connection, starting at the bunker end. Continue this until line is clear.
2. High and low bin signals on bunkers should be tested every 8 hr.
3. Do not feed pulverized coal into a bunker until two hours have elapsed from the time the high bin signal operates.
4. Bunker vents should be examined and cleaned once each week.
5. If lights are provided on screw conveyors to indicate conveyors are operating, these should be carefully watched so that stoppage of screw conveyor will be noted immediately. The whole conveying and preparation system should then be shut down at once.
6. Air ports in coal pumps should be kept clean. Cleaning of these once a day will improve pump operation.
7. Covers should never be removed from screw conveyors while conveyor is in operation.
8. Examine hopper over coal pump once each week, cleaning out if necessary.
9. Blow tanks should be closed tightly at all times when not in operation by closing the dust-tight gate, flapper valve, shut-off valve, valve in emergency line and air-operated cocks. If pressure builds up in blow tanks, leaky valves or cocks should be repaired.
10. If it is necessary to admit air into the blow tank with a slight amount of coal still remaining, air should not be admitted through the air jet piping, but through the large pipe provided at the top of the tank. The air jet should not be used until skirt pipe has been raised and shot has been started.
11. When the blow tank is shut down for a period of longer than 24 hours, the tank should be thoroughly inspected internally through the manhole to ascertain whether or not any fire or smouldering coal is in the tank. All blow tanks should be taken out of service at least once a week and accumulations of coal which cannot be removed by the regular transport system removed by hand.

352. Rotary Direct Fired Driers

1. The coal should be dried by heating the coal as little as possible.
2. If drier ceases to rotate for any length of time, fuel feed should be stopped.
3. Care should be taken to prevent any overloads which ultimately might cause stoppage.

353. Steam and Waste Gas Driers

1. Driers should be emptied twice a week and cleaned thoroughly with air.
2. Outlet air or gas duct should be cleaned with air every second day.
3. Driers should be inspected for steam leaks once each week.
4. Frequent inspections should be made during operating period for fires.
5. If drier is full of coal and mill is not operating, heat should be kept from coal in drier.
6. Drier and ducts should be inspected for fire when mill is not operating and drier is standing full of coal. Inspection of outlet duct should always be made before starting up drier.
7. Steam traps on steam heated driers should be maintained in good operating condition.
8. With waste gas driers, coal should be entirely run out before shutting down mill; coal and gas gates should be tightly closed.
9. Fire or hot coals should never be allowed to

remain in drier or under coal spout, and under no conditions allowed to enter mill.

354. Pulverizing Mills, Exhausters and Collectors

1. Do not allow mill to run empty.
2. Make routine inspection of puff doors and wearing parts for leakage.
3. Clean out mill wind box once each day or more often if necessary.
4. If automatic feeders are provided, these should be set so that mill does not choke and motor is not overloaded.
5. Check weekly for capacity and fineness of product.
6. In case of unusual sound in mill, stop mill and inspect for cause.
7. On mills where explosion dampers are provided, these should be kept open when mills are not in operation. This is to take care of any accumulation of gas in mill or cyclone. Also, vent should be closed to drier duct while mill is down.
8. No hand holes should be opened when equipment is in operation.

355. Bunkers

1. Bunkers serving boilers to be out of service for more than 100 hr. should be emptied and feeders cleaned out.
2. Bunkers serving boilers to be out of service for less than 100 hr. coal gates above feeders should be closed and coal feeders run out before laying off boilers.
3. Bunker vents should be checked once each day and cleaned once each week.
4. Information as to when a boiler is banked should be given to operator responsible for filling bunkers, so that no more coal will be added to that bunker until boiler again begins steaming.
5. Do not open man-hole or inspection openings in pulverized coal bunkers while fuel is being discharged into these bunkers.

356. Lighting Fires (Unit System)

1. Care should be taken to keep clear of burners and other openings in furnace front in case of fire and smoke puffs when coal ignites.
2. Care should be taken to prevent visitors or employees from standing or passing in front of boiler when it is being lighted.
3. After burners have been lighted, all boiler instruments should be checked to see that they are operating properly.

357. General

1. Records should be kept of all troubles and replacements.
2. Proper periods should be established for general inspection of equipment. Inspections should be made regularly and logs maintained of these inspections.
3. All moving parts should be periodically lubricated. These periods should be established and equipment lubricated regularly.
4. Pulverized coal dust should not be permitted to leak from equipment or piping.
5. Leaks developing in any pulverized fuel equipment should be stopped and repaired at once.
6. Building and equipment should be kept clean at all times.
7. No maintenance work should be started on any equipment until the jumpers have been pulled and the motor switch tagged.
8. Records should be kept of all unusual operation and operating conditions.
9. Allow no fire, open flame, torches, burning or welding in the crushing, drying or pulverizing plant.

4—Fans

401. Forced Draft Fans—Starting

1. Inspect the entire unit's oiling system, seeing that supply of lubricant is ample, and, if of gravity or pressure feed, see that oil is feeding properly to all bearings.
2. Turn on cooling water to bearings.
3. If fan is steam driven, open drains and exhaust valve, warm up unit.
4. If fan is motor driven, have motor inspected by electrician, start unit slowly, making proper use of starting equipment.
5. Adjust dampers for forced draft operation.
6. Bring the unit up to speed.
7. Inspect the unit for vibration and, if noticeable, notify the engineer in charge of shift. If vibration is excessive, shut down unit, notifying engineer in charge of shift.
8. Close the drains.
9. Make final inspection of oiling system.
10. If main oil switch should trip for cause other than throwing from starting to running position before motor is up to speed; if fuse should blow; or, if circuit breaker should open, have inspection made by electrician and trouble corrected before starting again.

Forced Draft Fans—Shutting Down

1. Shut down the turbine or motor.
2. Adjust the dampers for operation with the fan unit shut down.
3. Shut off oiling system.
4. If turbine driven, close exhaust valve.
5. Turn off water cooling system.

402. Induced Draft Fans—Starting

1. Inspect the entire unit's oiling system, seeing that supply of lubricant is ample, and if of gravity or pressure feed see that oil is feeding properly to all bearings.
2. Turn on cooling water to bearings.
3. If fan is steam driven, open exhaust valve and drains, warm up unit.
4. If fan is motor driven, start unit slowly, making proper use of starting equipment.
5. Adjust dampers for induced draft operation.
6. Bring the unit up to speed.
7. Inspect the unit for vibration and, if noticeable, notify the engineer in charge of shift; if excessive, shut down unit, notifying the engineer in charge of shift.
8. If main oil switch should trip for cause other

than throwing from starting to running position before motor is up to speed, if fuse should blow, or if circuit breaker should open, have inspection made by electrician and trouble corrected before starting again.

9. Close the cylinder drains.
10. Make final inspection of oiling system.

Induced Draft Fans—Shutting Down

1. Shut down turbine or motor.
2. Adjust dampers for operation with the fan unit shut down.
3. Shut off oiling system if of pressure or gravity feed.
4. If turbine driven, close exhaust valve.
5. Turn off water cooling system.

5—Boiler Feed Pumps

501. Boiler Feed Pumps—Centrifugal Type—Starting

1. See that valve on pressure gage line on discharge side of pump is open.
2. See that the suction and discharge valves are open.
3. If unit is steam driven, open drains and exhaust valves, warm up unit.
4. Turn on water to packing gland seals.
5. See that all valves to pressure regulator are closed.
6. See that cooling water is on bearing.
7. Inspect the entire unit's oiling system, seeing that supply of lubricant is ample, and, if of gravity or pressure feed, see that oil is feeding properly to all bearings.
8. Start the turbine or motor slowly and gradually bring up to working pressure.
9. Close all drains.
10. See that the proper pressure is on the equalizing pipes to balance the thrust.
11. Open steam and water line valves to pressure regulator.
12. Adjust the regulator to give the proper differential between the feed pressure and the steam pressure.
13. When pumps that are not equipped with a load equalizing device are run in parallel, the load may be equalized by slowing down the speed of the pumps which are taking the most load.
14. Open spray line valve if the pump becomes steam bound.

Boiler Feed Pumps—Centrifugal Type—Shutting Down

1. Shut down turbine or motor and see that pump comes to rest.
2. Close spray line valve if open.
3. Shut off oiling system if of pressure or gravity feed.
4. Close turbine exhaust valve and open the drain.
5. Close suction and discharge valves.
6. Shut off cooling water from bearings and seals.
7. Close steam line to pressure regulator.
8. Adjust water line valve to pressure regulator according to regular practice.

502. Boiler Feed Pumps—Plunger Type—Starting

1. Open steam cylinder drains and exhaust valve, warm up unit.
2. See that suction and discharge valves are open.
3. See that the feed line pressure gage valve is open.
4. See that the lubricator is full of oil and feeding properly.
5. Oil valve gear.
6. Bring up the pump speed for the desired pressure.
7. Close the drains.

Boiler Feed Pumps—Plunger Type—Shutting Down

1. Close the throttle valve.
2. Close the exhaust valve.
3. Turn off lubricator.
4. Close suction and discharge valves.

6—Feed Water Heaters

601. Putting a Heater on the Line—Open Type

1. See that water drains are open.
2. See that vents on heater are open and remain open.
3. Open the exhaust valve slowly.
4. Close drain valves.
5. Open water inlet valve slowly and fill to overflow.
6. See that the gage glasses are open and in operation.
7. Partly open the discharge valve to boiler feed pump suction line.
8. See that float valves are operating freely.
9. See that the water seal is open and working properly.
10. When the operating temperature is reached, open wide the water inlet and discharge valves.
11. See that the proper amount of pressure is obtained on the exhaust line header.
12. Open all trap discharge lines that lead to heater.
13. See that the valve on the connection between the heater and the float tank of the weir recording apparatus is open.
14. See that the heater divides the load equally and that the meter mechanism is operating properly.

602. Taking a Heater Off the Line—Open Type

1. Close the exhaust valve.
2. Partly close the water feed valve and allow water to reach minimum level.
3. Divert all trap discharges entering heater to other heaters or free blow.
4. Divert feed pump suction.
5. Close water supply valve.
6. Close the discharge valve to the pump suction line.

603. Putting a Heater on the Line—Closed Type

1. See that all vents are open.
2. Open the water inlet valve slowly and, when air has been eliminated, close vents.

3. Open the discharge valve to boiler feed pump suction line.
4. Open the valve in the equalizing line to the condenser.
5. See that the steam trap is in operating condition and closed.
6. See that all drain lines from the steam piping are open.
7. Open the steam inlet valve slowly.
8. Open all trap discharge lines that lead to the heater.
9. See that the heater relief valves are sealed.
10. If there is a check valve in the steam line to the heater, see that this valve is in operating condition and open.
11. See that the high water alarm is operating.

604. Taking a Heater Off the Line—Closed Type

1. Close the steam inlet valve slowly.
2. Divert all trap discharges entering the heater to other heaters or free blow.
3. Close the valve in the equalizing line to the condenser.
4. Divert the boiler feed pump suction.
5. Close the water supply valve.
6. Close the discharge valves to the pump suction line.

7—Evaporators

701. Putting an Evaporator Into Service

1. See that the water supply lines and exhaust steam lines to the evaporator heater are in operating condition.
2. Start the evaporator feed pumps.
3. See that all blow down valves are closed and that the vent of each shell is open.
4. Fill each shell to the running water level, as indicated by the mark on the shell (....) in. above the center line of the manifold.
5. Open the vents on the traps on both high and low pressure coils.
6. Open wide the vapor valve on the first effect.
7. Open the vapor valve on the second effect.
8. Open slowly the high pressure steam valve to the first effect coils, noting that the reducing valve maintains (....) lb. gage pressure.
9. Maintain (....) steam temperature by adjusting the boiler feed water supply to the de-superheater.
10. See that the trap is functioning on the steam separator.
11. Close the vents on the shells when the steam appears.
12. Slowly build up pressure in the shell of the first effect to (....) lb. by increasing the live steam to the coils of the first effect until (....) lb. at (....) deg. fahr. is maintained at the entrance of the coils.

702. Taking an Evaporator Out of Service

1. Close the high pressure steam valve to the first effect coils.
2. Close the water line to the de-superheater.
3. See that the float valves shut off the water after evaporation stops.
4. Close the vapor valve on the second effect shell.
5. Shut down the evaporator feed pump.
6. If the heater is to be taken out of service, see second section of rules for feed water heaters.

703. Cracking Down Evaporators—First Effect

1. Close the hand valve on the automatic feed water valve control.
2. Close the steam valve to the coil and blow down the first effect evaporator shell completely through the blow-down line.
3. Close the blow-down valve.
4. Open the vent valve.
5. Fill the first effect evaporator with cold filtered raw water to the top of the gage glass.
6. Close the vent valve.
7. Close the vapor valve on the first effect.
8. Open suddenly the steam valve to the first effect coil.
9. Close the steam valve when the cracking ceases, and see that the pressure does not exceed (....) or (....) lb. in the shell.
10. Blow down completely the shell to the waste discharge.
11. Close the blow-down valve.
12. Open the hand valve on the automatic feed water valve control.
13. See that the shell fills with hot water to the normal running level.

704. Cracking Down Evaporators—Second Effect

1. Close the hand valve on the automatic feed water valve control.
2. Close the vapor valve on the second effect.
3. Open the vent on the low pressure shell.
4. Blow down the shell completely through the blow-down valve.
5. Close the blow-down valve.
6. Fill the second effect evaporator with cold filtered raw water to the top of the gage glass.
7. Close the vent valve.
8. Admit steam suddenly to the second effect coils through the steam line connected to the vapor line. Do not exceed (....) lb. pressure.
9. Close the steam valve when the cracking ceases, and see that the pressure does not exceed (....) lb. on the shell.
10. Blow down completely the shell to the waste discharge.
11. Close the blow-down valve.
12. Open the hand valve on the automatic feed water valve control.
13. See that the shell fills with hot water to the normal running level.

705. Putting Evaporators in Service After Cracking Down

1. Open the vapor valves.
2. Proceed to put in operation according to rules for "Putting an Evaporator into Service."

B—ROUTINE CARE AND MAINTENANCE

1—Boilers

1001. General

1. Before entering a boiler, see that all safety rules have been complied with.

2. Men working on boiler should report any leakage, or any indication of leaks, in joints or where tubes enter the header.

1002. External Cleaning

1. Blow the soot from the boiler and superheater tubes and exposed surfaces of drums with compressed air or dry steam.

2. Clean the tubes of all clinker formation and remove the clinker, when and where necessary, from the walls of the furnace, taking care not to injure the brick work.

3. Clean the combustion and soot chambers.

4-s. Clean the branch air duct and under-grate air compartments, and examine dampers.

5. Inspect and repair brick work, arches and baffles.

6-s. Clean air openings in grate surfaces and replace castings where necessary.

7-s. Clean the water back heater compartment.

8. Thoroughly clean and paint all exterior surfaces of boiler when necessary, applying a paint that is suitable for this service.

9. Inspect all valves periodically, and overhaul if necessary.

10. Inspect and repair piping when necessary.

11. Examine bolts in flanges periodically.

1003. Internal Cleaning

1. Boiler tubes must be bored according to the schedule made by the constituted authority.

2. See all rules for "Taking a Boiler off the Line."

3. Remove scale with cone cutter. Boring schedule should be such as to never necessitate use of hammer.

4. See that the proper handhole or manhole caps are removed to permit ready removal of loosened scale.

5. Block, screen, or disconnect the blow-down pipes at the mud drum to prevent scale from going into blow-down piping.

6. Insert the machine in the end of the tube before starting.

7. Start the machine.

8. After the machine has entered tube about 1 ft., water should be fed into the tube behind the cutter.

9. Machine should be fed backward and forward at all times, making a gradual advance through the tube.

10. Repeat the operation until the tube is clean.

11. Use follower to determine proper gage.

12. Oil the boring machine when necessary, using a mineral oil.

13. See that no excess oil drips from the machine.

14. After all the tubes have been bored clean, wash out the tubes with water, or blow out with compressed air.

15. Remove the scale from the drum or header base.

16. Take down the dry pipes, when necessary, and clean all of the openings and holes. Also make sure the internal feed pipes are clean.

17. Clean interior surface of all drums.

18. Clean the superheater when necessary.

Owing to sharp curves and the presence of a core in some types of superheater tubes, it is difficult to get anything that will pass through them. A piece of cable stubbed on the end should be pushed through the tubes not having a core. The tubes should then be blown out with compressed air.

19. After all the internal surfaces have been scaled, wash out with water.

20. Put into working order the blow-down pipes as affected by rule (5).

21. Examine manhole and handhole gaskets, and replace when necessary.

22. Examine the tube handhole covers, bolts, etc., for cracks and replace those defective.

23. When boiler is closed, fill with water at about 90 deg. fahr. preparatory to a hydrostatic test.

24. When making the hydrostatic test "blank off" the automatic non-return valve and clamp down the safety valves.

25. After completing hydrostatic test, drain to normal water level and remove blanks and clamps.

26. Inspect the water column fittings and connections at least annually, and overhaul if necessary.

27. When gage glasses are replaced, see that there is no metal to glass contact or twisting strain, and that the glands are replaced directly in line.

28. Inspect all valves on the boiler and blow-down lines at least annually and overhaul if necessary.

29. Inspect all safety valves at least annually and overhaul if necessary.

30. Inspect pipe and drum covering annually and repair if necessary.

1004. Preparation for Inspection

1. Boilers must be taken off the line once a year for insurance inspection.

2. Before starting to clean a boiler for inspection, see that all safety rules and all rules for "Taking a Boiler off the Line" have been complied with.

3. Following the rules under "External Cleaning" and "Internal Cleaning."

1005. Economizers

1. Economizers should be considered as boilers and given the same inspection and cleaning. See rules for "External Cleaning," "Internal Cleaning" and "Preparation for Inspection."

2. When an economizer is uncapped, all tubes should be carefully inspected for internal pitting.

1006. Stokers

1. Clean the external mechanism daily.

2. Gear boxes should be inspected periodically, and lubricant renewed when necessary.

3. Brush chains clean and oil daily.

4. Chains and all bearing oil holes should be pro-

tected from dirt and accidental contact by workmen with a suitable housing.

5. Inspect and oil the line shaft when necessary.
6. Examine the clutches and bushings periodically.

1007. Stoker and Fan Motors

1. Lubricate and clean the bearings periodically.
2. If ball bearing motors are used, repack bearings periodically.
3. Motors should be thoroughly cleaned periodically as directed by constituted authority.

2—Boiler Auxiliaries

2001. Fans

1. Clean the induced and forced draft fans, dampers, housings and flues periodically.
2. Always complete cleaning before the fan is restored to service, in order to avoid unbalancing.
3. Inspect the bearings and couplings, the fan runners, and the stay rods for wear and corrosion periodically when out of service.
4. Change the bearing lubricant periodically.
5. The parts subject to wear and corrosion should be painted, or treated, to prevent or retard such action if once started.

2002. Feed Water Heaters

1. Overhaul the control valves and float mechanisms on the heaters periodically.
2. Oil valve stems and float mechanisms as conditions require.
3. Inspect the heaters periodically and clean when necessary.
4. On closed heaters, test for tube leakage periodically by:
    (1) Opening the heater drain with the steam shut off.
    (2) Raising water pressure to (....) lb. and observing the drain for leakage.

2003. Evaporators

1. Remove the coils from the shells periodically and inspect for scale formation.
2. If the scale has not been completely removed by the daily cracking down process, remove the coils from the headers and clean tubes and headers according to rules made by the constituted authority.
3. Test coil joints for leakage.
4. Inspect the evaporator auxiliary heaters as under "Feed Water Heaters."
5. Inspect interior of shell for corrosion and clean and paint when necessary.
6. Examine the blow-down valves periodically for leakage.
7. Test the safety valve periodically: first effect at (....) lb. gage pressure, second effect at (....) lb. gage pressure.
8. Overhaul all feed and steam control valves periodically.

2004. Soot Blowers

1. Inspect the external operating mechanism to see that it is not broken or fouled. This inspection is to be made during operation.
2. See that the drain on steam line is clear and kept open when blowers are not in use.
3. See that the vents are open.
4. Check position of steps or cams with respect to nozzles and reset, if necessary, when the boiler is down for external cleaning.
5. Examine boiler tubes, baffles and arches for steam cutting every time the boiler is down.
6. Inspect elements and bearings and repair when necessary, when boiler is down for external cleaning.

3—Instruments

3001. Draft Gages—Oil Type

1. Check daily for zero and add oil when necessary.
2. On becoming sluggish and dirty, tubes should be cleaned with kerosene and blown out with air. Pipe connections should also be blown out.
3. Test lines periodically for leakage.
4. Check gage periodically with standard gage.

Draft Gages—Diaphragm or Floating Bell Type

1. Check for zero daily.
2. Check the scale periodically with standard gage.

3002. Pressure Gages

1. Check in place monthly with standard test gage, or oftener if necessary.
2. Calibrate annually with deadweight tester, or oftener if necessary.

3003. CO_2 Recorders

1. Blow out the sampling lines daily, and see that they are kept free from soot.

[NOTE: Where ceramic filters are used at the sampling point, do not allow air pressure to act on these filters. Ceramic filters should be removed and cleaned every 90 days, or oftener if necessary.]

2. Replace the filtering material when necessary.
3. Check for zero daily.
4. Check for leaks weekly.
5. On chemical type recorders, replace the absorbent when necessary.
6. On electrical type recorders, check the balance of the electrical system on air weekly.
7. Check for accuracy daily, with Orsat, and report results to the properly constituted authority.
8. Clean the machine externally daily.
9. Clean internally as required.

3004. Flowmeters

1. Clean the meter externally daily.
2. Blow out the pressure differential-producing element and the lines to the manometer monthly, or oftener if necessary.
3. Check for leaks monthly.
4. Inspect, check for zero, and run a water column calibration every two months, or oftener if necessary.
5. Check the level of the condensers and the slope of the lines for possible air pockets periodically.

6. Inspect the recording pen, and clean or replace monthly.

7. Clean the manometer body and refill yearly, or oftener if necessary.

8. Clean the meter mechanism yearly, or oftener if necessary.

3005. Venturi Meters

1. Blow out the lines to the manometer monthly, or oftener if necessary.

2. Vent the meter at the manometer weekly.

3. Follow rules "3004-1, 3, 4, 6, 7, 8."

3006. V-Notch Meters

1. Check the zero monthly with weir measurement meter, the tank being out of service.

2. Check the external meter mechanism weekly.

3. Check the clock and integrator monthly.

4. Lubricate when necessary.

5. Inspect the float monthly for leaks and sediment, and clean same.

6. Inspect the weirs for corrosion and change in level monthly.

7. Areas affected by corrosion or wear should be treated by some means to maintain accuracy.

8. Repack float valve stem periodically.

SECTION II—PRIME MOVER PLANT

A—GENERAL OPERATION

1—Turbines

101. Inspection Before Taking Over Shift

1. The engineer coming on must receive a report covering all matters pertaining to the operating conditions of all apparatus from the retiring engineer.

2. The engineer must vertify this report by personal inspection of all apparatus.

3. The engineer must see that he has sufficient force on hand to operate his shift before the men on the previous shift are allowed to leave.

4. The engineer should see that sufficient apparatus is available for expected load.

5. The engineer or instrument man must take all meter readings and change all charts on the (. . . .) shift. The engineer shall verify the design and date on all charts before their removal.

102. Procedure Before Starting

1. Notify boiler room as to steam requirements.

2. Remove all bolts, tools, etc., which may have been left on or near the machine, and if any repairs have been made while machine was down examine position of all valves on entire unit.

3. Make a general inspection to see that the machine and auxiliaries are in proper condition for operation, and that duplicate auxiliaries (where provided) are in readiness for emergency use.

4. When a gravity lubricating system is used, see that sufficient oil is in the system and that oil in proper quantities is being supplied to all bearings.

103. Vertical Turbines—Starting

1. Notify switchboard operator that machine is ready to be warmed up.

2. After receiving affirmative reply, start high pressure accumulator pumps and bring accumulator pressure to (. . . .) lb.

3. See that oil is being supplied to main bearings of turbine and generator, and that overflow sights, alarms, etc., are in working order.

4. See that strainers in governor oil line are clean and that the governor oil pump air chamber is charged with sufficient air for cushioning.

5. Start governor oil pump and see that it is operating under correct pressure, supplying oil in sufficient quantities to all bearings throughout the system.

6. Turn on water to all water seals.

7. Start circulating pump and air pump, giving proper attention to the priming of the circulating pump and the removing of air from the water side of condenser.

[NOTE: If equipped with barometric condenser, rule to cover specific equipment and practice should be made by the constituted authority and inserted here.]

8. Examine all gages and see that steam gages show proper pressure; step gages show proper pressure; governor oil gages show proper pressure and vacuum gages show proper vacuum.

9. If the step gage does not show the proper pressure, make the necessary adjustments to attain this pressure, checking same with test gage.

10. Start the hotwell pump.

[NOTE: Hotwell pump should be started when high water alarm signal operates, with discharge throttled to hold proper level of water above pump while starting.]

11. Turn on steam to turbine seals.

[NOTE: Steam should be applied to seals just before starting up, so that no stresses will be set up by localized heating of stationary shaft.]

12. Open the throttle quickly until the first stage pressure gage registers (. . . .) lb. pressure and maintains this pressure.

13. As soon as the machine turns over, reduce throttle opening to the point where the spindle revolves at from 100 to 200 r.p.m.

[NOTE: Vacuum during warming up process to be such that temperature through low pressure portions of turbine will approximate temperature of operating conditions.]

14. If specific practice is to trip throttle during starting up operations, rule to cover this feature should be made by the constituted authority, and inserted here.

[NOTE: It is recommended that this rule be related to the above rules 12 and 13, so that tripping is effected when the valve has a small opening, as it is most conducive to sticking at this time.]

15. See that all turbine drains are open.

[NOTE: Open drains when same will not seriously interfere with vacuum. In case draining and sealing are effected through the same line, rule to cover specific practice and equipment should be made by the constituted authority and inserted here.]

16. Listen for internal rubbing until turbine goes into service.

17. Time required for warming up machine will be (....) min. per 100 kw. capacity.

18. During the warming up process, as the vacuum rises, make necessary adjustments of steam supplied to the seals.

19. Close turbine drains when machine is sufficiently warmed up.

20. Turn on water to oil cooling coils.

[NOTE: Water valve to oil cooler should be cracked slightly after turbine is started to keep water circulating through cooler to prevent a sudden change of temperature in the cooler.]

21. When unit is warmed up, notify switchboard operator that machine is ready for operating speed.

22. After receiving affirmative reply, open the throttle until the first stage pressure registers (....) lb. and maintain this pressure until the machine comes up to speed, which will be indicated by the closing of the admission valves by the governor and a reduction of the first stage pressure below normal starting pressure.

22-a. As the machine comes up to speed watch for vibration and do not operate on critical speeds longer than necessary.

[NOTE: This rule to be made specific by the constituted authority in accordance with turbine manufacturer's node data.]

23. Open the throttle wide, noting that no increase takes place in the first stage pressure, or in the turbine speed as shown by the speed indicator.

24. Close the throttle valve until it is sufficiently in advance of the governor to carry the synchronizing load.

25. Notify the switchboard operator that the machine is ready for "load."

26. After receiving affirmative reply, synchronize the machine as quickly as possible and apply load up to (....) kw.

27. See that vacuum is at a maximum.

28. Build up load on the machine at the rate of approximately (....) kw. per min.

[NOTE: As the load comes on, the opening of the throttle valve should be gradually increased and kept in advance of the governor.]

29. When machine is carrying approximately (....) kw., open the throttle wide and regulate the amount of steam supplied to the seals.

30. Make general inspection of all gages and oil temperatures from all bearings.

31. Watch the step bearing gages and see that they are maintained at the proper pressure.

Vertical Turbines—Shutting Down

1. After being notified by the switchboard operator that the load is to be taken off the machine, observe the first stage pressure, and when this pressure recedes to (....) lb., admit steam to the top seal.

2. After being notified by the switchboard operator to "stop" the machine, close the throttle slowly.

[NOTE: If specific practice is to close throttle with hand trip while shutting down, rule to cover this operation should be made by the constituted authority, and inserted here.]

3. Shut down the auxiliary pumps, except oil and step pump.

4. Break vacuum when machine is approximately (....) per cent below operating speed.

5. After vacuum has been destroyed, shut off steam and water to all seals.

[NOTE: In case bottom seal prevents oil leaking into condenser, do not shut off steam to same until machine comes to rest.]

6. After the machine has come to rest, shut down oil and step pump, shut off the oil supply to all bearings, and the water to oil cooler.

7. See that all admission valves have been opened by the governor.

8. Make a general inspection of the turbine.

9. Lubricate admission valves with a high grade cylinder oil mixed with a small quantity of graphite.

104. Horizontal Turbines—Starting

1. Notify switchboard operator that machine is ready to be warmed up.

2. After receiving the affirmative reply, start the auxiliary oil pump and see that it is operating under correct pressure.

3. Start the circulating pump and air pump, giving proper attention to the priming of the circulating pump and the removing of air from the water side of condenser.

4. See that oil is circulating to all main bearings —check oil filter operation.

5. See that governor is being supplied with oil.

6. Rule to cover any trying out of speed control mechanisms while machine is stationary should be made by the constituted authority and inserted here.

7. Examine all gages and see that steam gages show proper pressure; vacuum gages show proper vacuum and oil and water gages show proper pressure.

8. Start the hotwell pump.

[NOTE: Hotwell pump should be started when high water alarm signal operates, with discharge throttled to hold proper level of water above pump while warming up the turbine.]

9. Turn on steam to turbine seals.

[NOTE: Steam should be applied to seals just before starting up, so that no stresses will be set up by localized heating of stationary shaft.]

10. See that all turbine drains are open.

[NOTE: Open drains when same will not seriously interfere with vacuum. In case draining and sealing are effected through the same line, rule to cover specific practice and equipment should be made by the constituted authority and inserted here.]

11. Open the throttle quickly until the first stage pressure gage registers (....) lb.

12. As soon as the spindle starts rolling, close

the throttle to point where machine's speed is at desired rate for warming up the unit.

[NOTE: Vacuum during warming up process to be such that temperature through low pressure portion of turbine will approximate temperature of operating conditions.]

13. If specific practice is to trip throttle during starting up operations, rule to cover this feature should be made by the constituted authority and inserted here.

[NOTE: It is recommended that this rule be related to the above rules No. 11 and 12, so that tripping is effected when the valve has a small opening, as it is most conducive to sticking at this time.]

14. Listen for internal rubbing until turbine goes into service.

15. With spindle revolving, turn on water to water seals.

16. Turn on cooling water to oil cooler and main bearings.

[NOTE: Water valve to oil cooler should be cracked slightly after turbine is started to keep water circulating through cooler to prevent a sudden change of temperature in cooler. A close watch on oil temperatures will determine further regulations to oil cooler circulating water, and the time to turn on cooling water to main bearings.]

17. When unit is warmed up, notify switchboard operator that machine is ready for operating speed.

18. After receiving affirmative reply, open the throttle until the first stage pressure registers (....) lb., and maintain this pressure until the machine comes up to speed, which will be indicated by the closing of the admission valves by the governor and a reduction of the first stage pressure below normal starting pressure.

18-a. If the machine is equipped with an oil pump operated off the turbine shaft, see that this pump goes into service as the machine comes up to speed and that the auxiliary oil pump slows down to a very slow, but continuous, speed.

18-b. As the machine comes up to speed, watch for vibration and do not operate on critical speeds longer than necessary.

[NOTE: This rule to be made specific by the constituted authority, in accordance with turbine manufacturers' node data.]

19. Open the throttle wide, noting that no increase takes place in the first stage pressure, or in the turbine speed as shown by the speed indicator.

20. Close the throttle valve until it is sufficiently in advance of the governor to carry the synchronizing load.

21. Notify the switchboard operator that the machine is ready for "load."

22. After receiving affirmative reply synchronize the machine as quickly as possible and apply load up to (....) kw.

23. See that vacuum is at a maximum.

24. Build up load on the machine at the rate of approximately (....) kw. per min.

[NOTE: As the load comes on, the opening of the throttle valve should be gradually increased and kept in advance of the governor.]

25. When machine is carrying approximately (....) kw., open the throttle wide and regulate the amount of steam supplied to the seals.

26. Make general inspection of all gages and oil temperatures from all bearings.

Horizontal Turbines—Shutting Down

1. After being notified by the switchboard operator that load is to be taken off the machine, stand by to regulate the sealing system as the load decreases.

2. Start the auxiliary oil pump by hand, to see that it will start properly.

3. After being notified by the switchboard operator to "stop" the machine, close the throttle slowly.

[NOTE: If the specific practice is to close the throttle with hand trip or oil relay while shutting down, rule to cover this operation should be made by the constituted authority and inserted here.]

4. See that the auxiliary oil pump starts as the machine slows down, and that proper pressure is maintained.

5. Break vacuum when machine is approximately (....) per cent below operating speed.

6. Shut off steam and water to seals, and open drains to see that valves are not leaking.

[NOTE: Do not shut off all the steam to seals until vacuum is destroyed because of the harmful effect resulting from cold air being drawn through the seal glands.]

7. After machine stops, shut off the oil and water supply to the main bearings and oil cooler.

[NOTE: Temperatures will be a guide in shutting off the water to water cooled bearings.]

8. Shut down the auxiliary oil pump.

9. See that the admission valves have been opened by the governor.

10. Open atmospheric relief valve drains.

11. Make a general inspection of the turbine.

12. Check the exhaust casing temperature for steam leakage past the throttle valve.

13. Lubricate admission valves with a high grade cylinder oil and a small quantity of graphite.

14. When the condenser circulating pumps are shut down, note that the condenser low water alarms operate.

105. Periodic Overspeed Tests on Turbines

These tests are to be made under the personal supervision of the shift supervisor.

1. Bring the turbine up to speed with field on the generator.

[NOTE: Time for bringing the machine up to speed should not be changed from ordinary practice for these tests.]

2. See that the machine remains at normal speed under control of the governor.

3. Close the throttle, and when the speed of the machine has dropped below normal make necessary adjustment so that machine will not be under control of the operating governor.

[NOTE: Rule to cover specific equipment and procedure to be made by the constituted authority and inserted here.]

4. Open the throttle and allow the machine to accelerate until the automatic overspeed device operates, and note the speed and frequency at which this takes place.

5. Do not relinquish hand control of the machine until it is certain that the throttle has entirely closed under the action of the automatic overspeed device, as indicated by immediate decrease in speed and first stage pressure.

6. If automatic overspeed device does not operate when the overspeed reaches approximately (....) per cent, trip the throttle by hand, overhaul overspeed mechanism and put in first class working order, as proved by further tests, before unit is put in service.

[NOTE 1: In case specific practice is to reduce overspeed during these tests by means other than tripping throttle, rule to cover this feature should be made by the constituted authority and inserted here.]

[NOTE 2: Provision should be made for adequately cushioning the throttle valve to prevent excessive wear on the valve seat.]

106. Test Made at Reduced Speed

1. If the turbine has been running, slowly close the throttle valve by hand and allow the turbine to come to rest.

2. Remove the handhole plate on the governor pedestal, and place on the emergency trip the weight provided for the purpose.

[NOTE: If the machine has stopped in such a position that the weight cannot be attached, open the throttle sufficiently to turn the turbine shaft, and trip the throttle immediately when the shaft starts to move. Repeat if necessary until machine stops in position where weight may be attached.]

3. Replace the handhole plate.

4. Bring the turbine up to speed slowly and note with tachometer and frequency meter the speed and frequency at which the emergency trip operates.

The control mechanism should be set so that the machine would operate at normal speed without the weight on the emergency trip.

5. After the throttle valve has operated properly under the action of the automatic overspeed device, operate the handwheel to the closed position and reset the throttle trip.

6. If the emergency trip does not operate before the machine has reached normal speed, close the throttle.

7. Allow the machine to come to rest.

8. Remove the handhole plate and remove the weight from the emergency trip. Overhaul the mechanism, putting same into satisfactory operating condition, as proved by further tests.

9. When tests are complete, remove weight and replace handhole plate.

2—Reciprocating Engines

201. Corliss Engines—Starting

1. Notify switchboard operator that machine is ready to be warmed up.

2. After receiving affirmative reply, see that all drains from the cylinder are open.

3. See that the drain and trap above the throttle valve are open.

4. See that the main exhaust valve is open.

5. If a compound engine, see that the receiver is drained.

6. See that the wrist plate is unlatched from the eccentric rod hook.

7. See that oil is running to the bearings of the engine.

8. See that the crank and cross head pit drains are open and free.

9. See that the cranks, cross heads and other movable parts are not obstructed by any foreign material.

10. See that the wrist pins, crank pins, eccentric straps and wrist plate pins are tight.

11. See that the valve gear nuts, etc., are tight.

12. See that the crank is in such a position that the engine will start readily.

13. See that the governor belt, when used, is in good condition and free from oil.

14. Examine all gages.

15. Oil the governor spindle and see that the dash pot has the necessary amount of oil.

16. Start the circulating, air and hotwell pumps, and get partial vacuum in the condenser.

[NOTE: Regulate hotwell pump so that proper water level is maintained above pump suction.]

17. See that the governor is hooked up on the safety pin.

18. Place the bar in the wrist plate of the engine.

19. Open the by-pass valve, or crack the throttle, admitting steam alternately to each end of the cylinder, warming it up and getting all the water out of the valve chest and cylinder.

[NOTE: Shifting of valve gear to permit steam to enter alternate ends of cylinder shall be done with throttle or by-pass valve closed, due to the wear and tear on the crank pins and boxes when this operation is performed under steam pressure.]

20. Open the throttle valve further until the engine revolves slowly, then engage the wrist plate with the eccentric rod hook.

21. See that the lubricator and oiling system are in operation.

22. Notify the switchboard operator that the machine is ready for operating speed.

23. After receiving affirmative reply, open the throttle slowly and close the by-pass valve, noting that the engine comes up to proper speed.

24. See that the safety pin of the governor is in a correct position to operate, should the governor belt break.

25. Close the drains.

26. Signal "Load" to the switchboard operator.

27. As the load comes on, bring the vacuum up to normal.

Corliss Engines—Shutting Down

1. After receiving the signal "Stand By" from the switchboard operator, answer it.

2. After receiving and answering the signal "Stop"

from the switchboard operator, close the throttle slowly until the engine comes almost, but not quite, to a stop.

3. Reverse the safety pin of the governor so that the governor will not drop to the lowest point.

4. Place the bar in the wrist plate.

5. Disconnect the wrist plate from the eccentric rod.

6. Operate the wrist plate by hand with the bar so that the engine will stop with the crank in starting position.

7. Move the wrist plate to central position so that the exhaust valves are closed.

8. If the engine has a double eccentric, trip the steam valves by hand when the wrist plate is in a central position, so that the steam valves may be closed and lapped.

[NOTE: A test should be made periodically by leaving the governor safety pin in the running position when shutting the throttle valve, to see that the safety device is in working order.]

9. Shut down the circulating, air and hotwell pumps.

[NOTE: If jet condenser is used, close off injection water just before closing throttle valve and allow air or wet vacuum pump to run until engine stops, thus obviating, to some extent, the possibility of water being forced by atmospheric pressure through air or wet vacuum pump into low pressure cylinder in the event of displaced or defective valves in the pump.]

10. Shut off the oiling system.

11. Open the drains.

3—Auxiliaries

301. Small Turbines on Auxiliaries—Starting

1. Inspect the reduction gear to see that no water has accumulated in the case, and that there is enough, but not too much, oil.

2. See that the exhaust valve is open.

3. See that the relief valve on the turbine casing is in operating condition.

4. Inspect the oiling system and the oil strainer, if it is accessible.

5. See that all drains are open.

6. If an emergency trip is provided, see that it is set.

7. See that the overload nozzle valves are closed.

8. If condensate has accumulated in the auxiliary steam line, drain it off.

9. Open the throttle slightly and run the unit at a low speed.

10. Sound the turbine.

11. Inspect the oiling system before and after starting to see if it is functioning properly.

12. Open and adjust the proper supply of water to the oil cooler and bearing water jacket, if any.

13. Bring the turbine up to speed gradually.

14. Close all drains when the turbine is up to speed.

15. If turbine glands are of the water sealed or steam sealed type, see that they are properly sealed.

16. Test the governor by pushing it to the closed position to see if this will cause the turbine to slow down.

17. Overload nozzles are to be used only when necessary.

Small Turbines on Auxiliaries—Shutting Down

1. See that load is off the turbine whenever practicable.

2. Close the throttle valve.

3. Do not shut off the oiling system until unit comes to rest.

4. Close exhaust valve every time machine is shut down.

5. Open the drains.

Small Turbines Periodic Overspeed Test

1. See that the load on the turbine has been removed, when practicable.

2. Apply a tachometer to the shaft and note that normal speed is maintained by the governor at no load.

3. Continue to observe the speed by means of the tachometer and force the governor arm against the spring, allowing the turbine to speed up, not exceeding 2 per cent above the speed at which the manufacturer recommends setting the emergency trip.

4. Note the speed at which the overspeed device trips the throttle, and, if this speed is more than 2 per cent above the speed at which the manufacturer recommends setting the emergency trip, locate cause and make any necessary adjustments to governor mechanism and safety devices.

5. Be sure tripping mechanism is correctly adjusted before putting machine into service.

302. Slide Valve Engines on Auxiliaries—Starting

1. Open the exhaust valve.

2. Open necessary valves on auxiliaries connected to the engine.

3. See that the drains and cylinder cocks are open.

4. See that the lubricator is acting properly and inspect the oiling system before and after starting.

5. Open the throttle valve enough to admit steam to warm up cylinder without turning engine.

6. Bring the engine up to speed gradually and inspect the operation of the governor and safety devices.

7. Close the drains.

Slide Valve Engines on Auxiliaries—Shutting Down

1. Close the throttle and stop the engine in the starting position.

2. Shut off the oiling system when the unit comes to rest.

3. Close all valves on auxiliaries connected to engine.

4. Close the valves on the lubricator.

5. Open the drains before closing the exhaust valve, if non-condensing.

6. Exhaust valve should be closed and drains open.

303. Small Motors on Auxiliaries

Synchronous Motors—Starting

1. See that load is off motor, if possible.

2. Inspect the oiling system.
3. If possible, throw field switch to short circuit the field windings; otherwise, see that field switch is open.
4. Close the starting switch and note that the rotor turns over.
5. After the motor comes up to maximum speed on the starting switch, open the starting switch and immediately close the running switch.
6. After the motor comes up to maximum speed on the running switch, see that all the field resistance is cut in, close the field switch and adjust the field for the minimum or the prescribed leading armature current.
7. Inspect the oiling system and note if it functions properly.

Synchronous Motors—Shutting Down

1. See that all load is off motor, if possible.
2. Open the running switch.
3. Cut all field resistance in.
4. Open the field switch.

Induction Motors Started by Compensator—Starting

1. Inspect the oiling system.
2. See that the compensator handle is in the "Off" position.
3. Close the motor main switch.
4. Throw the compensator handle to the starting position and note that the rotor turns over, or watch ammeter if it is impossible to see motor.
5. When the motor comes up to maximum speed on the starting position, throw the compensator handle to the running position quickly.
6. Inspect oiling system and note if it is functioning properly.

Induction Motors Started by Compensator—Shutting Down

1. Trip compensator.
2. Open the motor main switch when compensator handle is in "Off" position and motor has begun to slow down.

Motors Started from Automatic Control Panel—Starting

1. Inspect oiling system.
2. See that the controller is in the "Off" position.
3. Close the motor main switch.
4. Move the controller handle to the required starting position.
5. Note that the starting operations are in proper sequence, and that the motor comes up to the required speed.
6. Inspect the oiling system and note that it is functioning properly.
7. Inspect the slip rings if motor is of the slip ring type.

Motors Started from Automatic Control Panel—Shutting Down

1. Move the controller handle to the "Stop" position.
2. Open the motor main switch, wherever practicable.

[NOTE: If motor main switch is knife type, open switch when rotor has stopped turning.]

304. Circulating Pumps—Starting

1. Inspect the condenser for open doors and see that the vent on the tail pipe is open unless syphon is provided.
2. See that the condenser washout valve in the water box is closed.
3. See that the discharge valve is closed, if one is used.
4. Admit water to the seals of the pump.
5. Prime the pump by the means provided.
6. After the pump is filled with water, start the pump turning slowly.
7. See that the oiling system is operating properly.
8. See that the proper supply of water is being maintained on the coolers.
9. Run the pump at a speed that will maintain desired pressure on the pump.
10. Open the discharge valve until water appears or suction occurs at the vent on the tail pipe, if pump has this equipment.
11. Close the tail pipe vent and open the discharge valve wide, if the pump has this equipment, and bring the pump up to desired speed.
12. Shut off priming equipment when the pump delivers water.

Circulating Pumps—Shutting Down

1. Stop the pump.
2. Close the discharge valve, if necessary.
3. Shut off the water to the seals.
4. Shut off the water from the oil cooler.

305. Hydraulic Air Pump, Independently Driven—Starting

1. Admit water to the seals of the pump.
2. Open the hurling water priming valve until the desired pressure is reached.
3. Start the air pump at slow speed.
4. See that oiling system is working properly.
5. Bring the air pump to normal speed.
6. Change over from priming to normal hurling water.
7. See that normal vacuum is produced by the pump.
8. Open the air suction valve gradually and, if necessary, adjust the suction valve so that it functions properly.

Hydraulic Air Pump, Independently Driven—Shutting Down

1. Close the air suction valve.
2. Stop the pump.
3. Shut off the water to the seals.
4. Shut off the oiling system.
5. Close the hurling water suction valve after the pump has come to rest.

306. Steam Jet Air Pump, Two Stage Inter and After Surface Condenser Type—Starting

1. See that auxiliary cooling water is passing through the pump condenser, if pump is so equipped.

2. Open air suction pipe between main condenser and pump.

[NOTE: On pumps with multiple elements, open suction valves to all elements and bring all in operation on starting.]

3. See that the drain from the pump after-condenser is open.

4. Open steam throttle and pass steam through secondary nozzle.

5. Open equalizer drain between pump inter-condenser and main condenser.

6. Adjust steam throttle to secure proper working pressure.

7. When proper back pressure has been secured in the main condenser and the turbine put into operation, pass condensate from main condenser through the pump condenser instead of raw circulating water.

8. Open primary steam nozzles and bring the back pressure in the main condenser as low as possible.

[NOTE: On pumps with multiple elements use only as many elements as are necessary to remove the air.]

Steam Jet Air Pump, Two Stage Inter and After Surface Condenser Type—Shutting Down

1. Close the suction pipe between main condenser and pump.

2. Close the equalizer drain between pump inter-condenser and main condenser when pump has separate inter-condenser.

3. Close steam throttle.

307. Corliss Engine Driven Air and Circulating Pump—Starting

1. Open all drains from the steam cylinder.

2. Open the exhaust valves and exhaust line drains.

3. Disconnect the wrist plate from the eccentric rod hook.

4. See that the oiling system is working properly before and after starting.

5. See that the cranks, cross heads and other movable parts are not obstructed by any foreign material.

6. See that the cross head pins, crank pins and valve gear pins are tight.

7. See that the crank is in such a position that it will start readily.

8. Open the air cylinder discharge valve.

9. See that cooling water is turned on to the air cylinder jacket.

10. See that water is turned on to the circulating pump seals.

11. Prime the circulating pump by the means provided.

12. Open the discharge valve on the circulating pump.

[NOTE: Because of large clearances and absence of suction valves in certain pumps, it may be necessary to keep the discharge valve closed until the pump is turning over slowly.]

13. Place the bar in the wrist plate of the engine.

14. Open the throttle valve slightly and rock the valve gear with the bar, admitting steam alternately to each end of the cylinder, warming it up and allowing the piston to move backward and forward a number of times to clear the cylinder of water. Note whether any bearings are loose when rocking.

15. Close the throttle, then engage wrist plate with eccentric rod hook and lock it in place.

16. Open the throttle.

17. Turn the engine over slowly.

18. Open the suction valve of the circulating pump slowly and see that water starts to circulate.

19. Bring engine up to normal speed.

20. See that the oil pump is removing oil from the reservoir.

21. Close the drains.

22. Shut off priming equipment.

23. Open the air suction equalizing valve on the pump, if one is provided.

24. Open the air suction valve on the air pump.

25. See that there is no excessive leakage from the circulating pump glands.

26. See that the lubricators on the air valves and steam cylinders are operating.

Corliss Engine Driven Air and Circulating Pump—Shutting Down

1. Partly close the throttle valve.

2. Close the circulating pump suction valve.

3. Close the throttle until the engine is turning slowly.

4. Disengage the eccentric rod from the wrist plate and insert the bar.

5. Stop the engine in a starting position by rocking the wrist plate with the bar.

6. Close the main throttle valve.

7. Place the wrist plate in the central position.

8. Open drains before closing exhaust valve, if non-condensing.

9. Exhaust valve should be closed and drains opened.

10. Shut off the oiling system.

11. Close the air suction valve on the air pump.

12. Shut off water to air cylinder cooling jacket.

13. Close the discharge valve on the circulating pump.

14. Shut off water to the seals.

15. Make a general inspection.

308. Wet Pump, Centrifugal Type—Starting

1. Admit water to the seals.

2. Open the suction valve.

3. Open vacuum equalizing line.

4. Start the pump, turning slowly.

5. See that the oiling system is working properly.

6. Open the discharge valve, if not already open.

7. See that the proper water level is maintained in the hotwells to which the pump which is operating is connected.

[NOTE: If the water level rises and one pump does not meet the demand, a second pump must be put into operation. Look for air leaks around the pump on putting on the second pump.]

Wet Pump, Centrifugal Type—Shutting Down

1. Stop the pump.

2. Close the discharge valve, if pump is provided with check valve.
3. Close the suction valve, if necessary.
4. Close the vacuum equalizing line.
5. Shut off the water to the seals.

309. Surface Condensers—Periodic Test for Tube Leakage

Periodic tests should be made for leakage on surface condensers. There are several methods in general use for this purpose, two of which are outlined below.

While shutting down the turbine, a test should be made for leakage on the condenser, as follows:

1. Maintain as low a back pressure as possible in the steam space of the condenser.
2. With the suction valve of the wet pump closed (also the suction equalizing line when one is installed) note the rate at which water rises in the hotwell, deducting steam and water used for sealing. The rise of water in the hotwell under these conditions indicates a leakage of circulating water into the steam space.
3. Record in the daily log sheet the rate at which the water rises and the back pressure at that time.
4. When an additional chemical test is required, (a) take a one to two gallon sample of circulating water while the hotwell is filling; (b) take a one to two gallon sample of water in the hotwell immediately at the end of the test; (c) forward the samples to the laboratory for analysis.

When salt water or water unfit for boiler feed is used for circulating water, a test should be made each time a unit is put into service, regardless of how short a time it may run. It is also desirable to test each eight hours, or oftener, while on continuous runs. Chemical or electrical tests may be employed. The most commonly used method is that of titrating for chlorine where circulating water is salty. The measure of the outstanding quality of circulating water can be used in any case to determine the leakage.

310. Surface Condensers—Periodic Test for Air Leakage

1. Just before shutting down the turbine, close the suction valve to the air pumps and note time required for vacuum on condenser to drop one inch. This will give a measure of the air leakage.

[NOTE: Back pressure should be watched continuously during operation. Appreciable change at any given load may indicate a leakage.]

311. Jet Condensers—Test for Air Leakage

Fill the condenser with water up to turbine glands, and if there are any leaks, stop them.

312. Pumps, Plunger Type—Starting

1. See that the exhaust valve is open.
2. Open drains on steam cylinder and exhaust line.
3. See that the discharge valve is open.

[NOTE: If bypass is provided, pump should discharge back to the suction through bypass, when starting.]

4. Open the suction valve.

[NOTE: Where a pump is being started in parallel with another already in operation, the danger, due to air binding of the latter, caused by the opening of the suction valve on the incoming pump, particularly where there is a suction head, can be overcome by starting the incoming pump slowly, establishing a vacuum on its suction side somewhat greater than that on the pump in operation before opening the suction valve. Then when the suction valve of the incoming pump is opened the operation of the pump already in operation will not be affected.]

5. See that the lubricator is working properly and oil all moving parts both before and after starting.
6. Open the throttle valve and start slowly.
7. Bring the pump up to speed for the desired pressure.
8. Close the drains.

Pumps, Plunger Type—Shutting Down

1. Close the throttle valve.
2. Close the exhaust valve.
3. Turn off the lubricator.
4. Close suction valve.
5. Close discharge valve.

313. Accumulator Pumps—Starting

1. See that the exhaust valve on the steam end is open and that the exhaust line is drained.
2. See that the drains on the steam cylinder are open.
3. See that the suction and discharge valves are open and that all air is out of the pump.
4. See that the lubricator is working and oil all moving parts before and after starting.
5. Open the throttle sufficiently to warm cylinders.
6. Start the pump moving slowly and bring the accumulator slowly to the normal running position without sticking or binding.
7. Close the drains.
8. Examine glands and nuts.
9. See that pump does not speed up.
10. See that alarm signals are in service.

Accumulator Pumps—Shutting Down

1. Close the throttle slowly, allowing the accumulator to come slowly to the bottom stop.
2. Cut out alarm signals before accumulator reaches stop.
3. Open the drains.
4. Close the steam valves to the lubricators.
5. Close the suction and discharge valves.
6. Clean the strainers.
7. Exhaust valve should be closed.

314. Air Compressors, Synchronous Motor Driven—Starting

1. Close the suction valve.
2. Open bleeders on air cylinders and connections.
3. Open the water valves to the cooling jackets.
4. See that the oiling system is working properly, both before and after starting and do any necessary oiling previous to starting.
5. See that the discharge valve is closed.
6. Open the free exhaust valve on the discharge line.

7. Start the synchronous motor and bring it up to speed.
8. Open the discharge valve.
9. Close the free exhaust valve on the discharge line.
10. Open the suction valve.
11. Close all bleeder valves.
12. See that all control valves are working properly.

Air Compressors, Synchronous Motor Driven—Shutting Down

1. Stop the compressor.
2. Close the discharge valve.
3. Open the free exhaust valve on the discharge line.
4. Close the suction line.
5. Shut off the water supply to the cooling jacket.
6. Shut off the oiling system.

315. Air Compressors, Steam Driven—Starting

1. Open the exhaust valve.
2. See that the steam drain valves are open.
3. Open the bleeders on air cylinders and connections.
4. See that the oiling system is working properly both before and after starting and do any necessary oiling previous to starting.
5. Open the water valves to the cooling jackets.
6. Latch the cut-out valve in the closed position.
7. Open the throttle slightly and run the machine slowly while heating up.
8. Gradually open the throttle wide, bringing the compressor to speed.
9. See that the governor operates and holds the speed constant.
10. Close the bleeder and drain valves.
11. Release the cut-out valves.
12. When working pressure is almost reached, open the air discharge valve.
13. See that the cut-out valves and the control valves are operating properly.

Air Compressors, Steam Driven—Shutting Down

1. Latch the cut-out valve closed.
2. Close the air discharge valve if check valve is not used.
3. Close the throttle valve.
4. Open the drain valves.
5. Shut off the water supply to the cooling jackets.
6. Shut off the oiling system after the machine has stopped.
7. Shut off the lubricators.
8. The exhaust valve should be closed.

B—ROUTINE, CARE AND MAINTENANCE

1—Turbines

1001. General

1. Machines should always be kept as clean as possible and wiped periodically.
2. Inspect wheel and thrust clearances periodically and make necessary adjustments.
3. Make complete internal inspection of turbines periodically and make necessary repairs.

1002. Oiling System

1. Oil should be carefully watched, maintained in good condition and changed when necessary.
2. Clean the screens of the turbines oiling system periodically as required by local conditions.
3. Blow out the cooling coils of the oil cooling system when necessary, as shown by the oil and water temperatures.
4. Clean the oiling systems and gravity filter tanks when necessary.

1003. Governors

1. Examine the worms and gears of the governors periodically and repair same, if necessary.
2. Inspect the needle valve oil supply to the governor knife edges periodically.
3. The roller transmission (Gimbal bearings) of the governor should be given a thorough internal cleaning periodically and oiled as often as local conditions require.
4. A periodic examination of the overspeed device should be made as often as possible.

[NOTE: It should be definitely known each time the machine is started up that the overspeed device is in perfect operating condition, especially if the machine has been out of commission for some time. Because of differences in design and operating conditions, it is recommended that on vertical turbines examination should be made not less than once each week and on horizontal turbines not less than once each month.]

2—Auxiliaries

2001. Small Turbines and Reciprocating Engines on Auxiliaries

1. Insofar as they are applicable, Rules 1001, 1002 and 1003 should be followed.
2. The racks and pinions of valve gears should be scraped and cleaned periodically.

2002. Condensers

1. Examine the interior of condensers periodically.
2. Clean condenser tubes when necessary.

2003. Miscellaneous

1. Examine motor operated valves periodically and make necessary adjustments and repairs.
2. All remote control valves should be operated periodically.
3. All water strainers should be kept clean.
4. Operate the main valves of the forebays periodically, being sure adjacent valves are open as each is manipulated.
5. Clean out the debris from the bottom of the screen basin well and overhaul the apparatus periodically.

BOILER AND TURBINE ROOM INSTRUMENTS

GENERAL

Within the past decade there has been a decided change in the attitude of both designing and operating engineers toward the use of station instruments. The development of such instruments has necessarily been slow; they were expensive in first cost as well as maintenance and somewhat unreliable in their results. This was particularly true of instruments for boiler and turbine operation; and, when the boilers seldom exceeded 7000 sq. ft. of heating surface, and the turbines were small, the cost of the instrument was a large proportion of the total cost of the installation. With increasing size of the boiler units, as well as the generating units, the cost of an instrument installation has become a very small percentage of the total cost of the equipment.

The intelligent use of instruments has fully justified these expenditures and in consequence we find a tendency toward the use of extremely elaborate instrument installations. The Committee, while fully indorsing the extensive use of instruments as aids in proper operation, wishes to repeat a warning published in the report of 1923 which included the following paragraph:

> "The Committee wishes to offer one warning. It is believed better to install too few instruments than to install more than can be taken care of by the operating organization. There is nothing so disastrous as to install devices for improving economy which are not kept in operating condition constantly. The failure of such a device often destroys the confidence of the operating force in all of them and it is sometimes months before this confidence is restored."

In general, the Committee finds that boiler and turbine room instruments, as now offered by various manufacturers, show marked improvement in accuracy, reliability and decreased maintenance, but feel there is still room for further progress in these directions, particularly as to flow meters and instruments for the measurement of the temperature of water, gases and steam where weighted averages are so necessary for obtaining true efficiencies. It should be remembered, however, that these instruments are necessarily of a somewhat delicate construction and consequently need intelligent care and supervision.

In general, the measurement of steam and water quantities depends upon measurements of the drop in pressure across an orifice. A mistake in the size of the orifice introduces a constant error and, when the operating force is not equipped for the calculation of such orifices, some means of checking the meter readings should be used before full reliance is placed on them. The present practice of manufacturers seems to be to calibrate their meters for a constant coefficient of discharge, whereas, if the actual curve for this constant were used, a greater accuracy could be obtained.

The installation of an elaborate set of instruments does not of itself insure economical operation. The instruments are valuable tools which, when intelligently used, will assist in maintaining a higher operating economy than would otherwise be possible. Such an intelligent use of instruments is described in the report of the Committee on Station Betterment for this year.

CO_2 INSTRUMENTS FOR COMBUSTION CONTROL BOILER WATER LEVEL INDICATORS OR RECORDERS

The Committee endeavored to learn something of the present status among member companies as to the use of CO_2 instruments and boiler water level recorders as aids in boiler operation.

Replies were received from thirty-nine members, and these replies have been summarized below.

Co2 Instruments

About one-third do not use CO_2 instruments, and approximately two-thirds do, and while the latter do not approve wholeheartedly of the equipment, the consensus of opinion seems to be that they are an aid to the firemen and useful in combustion control.

The instruments used are of the chemical, mechanical and electrical types, with the chemical in the majority due, no doubt, to the fact that they have been on the market for a longer time than the others. Where other than the Orsat type alone is used, they are practically all of the recording type and many have, in addition, an indicator.

The favored location is on the boiler instrument panel, but in some instances other locations, such as the boiler room engineers' office, have been chosen.

Generally there is one instrument per boiler, though some plants have one instrument for a group of boilers.

It is the practice to check the instruments at regular periods, the intervals being daily, weekly or monthly as experience dictates, while the standard for comparison is in all cases the Orsat.

The accuracy varies within the limits of —0.5 per cent to +3.0 per cent of the Orsat reading and is fairly well maintained provided the instruments are given reasonable care.

Records may be continuous or intermittent with intervals between readings as much as five minutes.

The maintenance cost varies from "very small" in one case and "one man hour per day per instrument," in another, to "$4.00 per instrument per week" for a third with all the gradations between.

Gas samples, as a rule, are taken from one point at the center of the flue, though in several instances two or more points across the breeching are selected, and the gas with few exceptions is drawn through porous filters.

Publication No. 289-59. Serial Report, Prime Movers Committee.

Boiler Water Level Indicators or Recorders

These instruments, which are both recording and indicating, are reported by only five members who list four makes.

The instruments are said to be dependable, to require but little attention, to be easily installed by unskilled labor and to cost about the same as a flow meter.

The instruments are checked by comparison with the boiler gage glass, the comparison being made at intervals of 6 hr., 8 hr., twice a day, and in one case "almost constantly," as it is compared with the gage glass at every reading.

The reports do not, however, indicate that any of the members are giving serious thoughts at present to a general use of such instruments as a necessary or desirable adjunct to the regular water glass on the boiler drum.

STATEMENTS BY MEMBER COMPANIES

Statement by the Union Gas & Electric Co.

Ranarex CO_2 Recorders

"As a result of the success of a trial installation at West End Station, Ranarex CO_2 Recorders were included in the initial order of instruments for Columbia Station. The recorders installed at Columbia are not of the 'strip chart pin punch' type, but have disk charts, driven by 24-hr., spring-wound clocks, and the record is made by an inking pen.

"The strip chart on the trial installation gave considerable trouble. The chart at times would not feed and it was impossible to adjust the time of the chart with any degree of accuracy. The disk chart inking pen recorders have proved satisfactory. The quantity of ink in the pen does affect the reading, but this inaccuracy can be decreased by filling the pen at frequent intervals. The disk chart is superior to the strip chart for filing and reference.

"It is possible to operate the recorders by checking them to zero, but the increase in accuracy makes a daily Orsat check advisable. The filter and water legs are installed below the boiler operating floor, above a landing, making them easily accessible for inspection and eliminating unsightly piping near the recorder. An air line is provided for blowing out the line from the filter to the boiler. This line is blown every 24 hr. In addition, it has been found necessary to blow out the remainder of the piping with an air hose every two weeks.

"The cleaning, inspecting and checking is a routine daily job. For 6 recorders in operation the total time required is 4 man-hours per day. The recorder mechanism has needed but few repairs. It has been necessary to replace the can that contains the filter material by one made of copper, to prevent corrosion.

FIG. 1—Detail Drawing of Gas Cleaner for Ranarex CO_2 Recorder Used by the Union Gas & Electric Co.

"The recorder draws a large volume of gas and on pulverized fuel installations the sampling line becomes stopped with ash. This necessitates very frequent blowing of the line when the boilers are operated at high ratings. Fig. 1 shows a gas cleaner that has been used to good advantage in keeping the sampling lines clear. The gas sample is taken in the last pass of the boiler. The sample is taken into the cleaner through spiral vanes, which give it a circular motion. A pipe runs from the bottom of the cleaner to the economizer outlet where the draft is 1 in. of water more than in the third pass. This pipe serves both to produce high velocity through the vanes and to discharge a large per cent of the ash. The line to the recorder takes its sample from the center of the 'whirl' where there is the smallest amount of ash.

"This cleaner has given better results than porous filters installed on the end of the pipe. They were made at the plant by the welder. The vanes are made of 16-gage iron brazed to ¾-in. bolts and then brazed in position in the 3¾-in. length of 3-in. pipe.

CALIBRATION OF THERMOMETERS

In order to operate the modern power plant efficiently, it is necessary to obtain accurate temperature records of boiler feed water, condenser circulating water, boiler flue gas temperatures, etc. Various types of indicating and recording thermometers, having temperature ranges between 32 deg. fahr. and 2500 deg. fahr., are used to obtain these records.

The mercury thermometer is the commonest of the indicating instruments used for such purposes, temperatures as high as 950 deg. fahr. being measured with this type of thermometer. Recording thermometers, of the mercury, vapor tension or gas type are also extensively used.

When it is desirable to measure temperatures at inaccessible points, or to measure temperatures higher than 950 deg. fahr., thermocouples and resistance thermometers are generally most suitable.

To obtain reliable temperature readings with any type of thermometer, great care must be taken not only to install the instrument properly, but also to make sure of the accuracy of the instrument itself. Since the calibration of practically any thermometer is subject to change, it is advisable that occasional checks be made with a suitable standard. This is particularly necessary with recording instruments which are quite apt to change their calibration.

In order to obtain an accurate check, it is necessary to keep the sensitive element of both the thermometer under test and the standard at exactly the same temperature, since the accuracy of the check depends on the uniformity in temperature of the test bath.

It is thought, therefore, that the descriptions of the laboratory methods used by several member companies for this work will be of interest.

Methods of Calibration of Thermometers and Pyrometers

STATEMENT BY DETROIT EDISON CO.

Engraved Stem Glass Thermometers

Apparatus

"For temperatures up to 550 deg. fahr. an electrically heated oil bath with stirring attachment similar to that described in the A.S.M.E. Power Test Code (Instruments and Apparatus) is used.

"For temperatures between 550 deg. fahr. and 800 deg. fahr., a similar bath of sodium and potassium nitrate is used.

Calibration

"The purpose for which the thermometer is to be used governs the general calibration method.

"For instance, a general service thermometer having a range of 30 deg. fahr. to 800 deg. fahr. is checked at any desired immersion against a standard resistance thermometer at every 50 deg. fahr. on both an increasing and decreasing temperature curve.

"Thermometers for special service or for some particular range where a high degree of accuracy is required are checked at a desired immersion against a standard resistance thermometer at intervals of 10 deg. fahr. somewhat above and below the range when in use. The emergent stem temperature of such thermometers is usually determined during the calibration so that steam temperature correction can be applied to field readings to cover any difference between stem temperatures during calibration and field conditions. The corrections are determined by reference to the A.S.M.E. Power Test Codes, Instruments and Apparatus Section.

Industrial Thermometers

"The same apparatus and method is used as for engraved stem thermometers, the industrial type being screwed into tapped holes arranged inside of the tank for this purpose.

Recording Thermometers

(Metal tube extended bulb-types)

Low Range—0 deg. fahr. to 220 deg. fahr.

"The metal bulbs are removed from the thermometer well or protection tube. Several bulbs are wired together with bare copper wire and immersed in a bucket of water. One standard glass stem thermometer is tied to the group of metal bulbs using a small pad of tinfoil around the bulb of the standard thermometer; another standard thermometer is placed a few inches away from the group of bulbs under test.

"The recorders are mounted on a convenient board as near the bucket as possible with the extension tubes coiled up to a circle approximately 1 ft. in diameter. The whole assembly is allowed to stand overnight so as to assume room temperature of as close to 70 deg. fahr. as possible before making the calibration test.

"Readings are taken against the standard thermometer every 10 deg. fahr., the temperature of the water bath being raised by adding, and stirring well, hot water to the water in the bath.

High Range—above 212 deg. fahr.

"These are checked against standard engraved stem thermometer by immersion of the bulbs in first the oil and then the nitrate bath, readings against the standard being taken every 50 deg. fahr., while heating and cooling.

Thermocouples

Apparatus

"For low range thermocouples the calibration is carried out in the baths used for thermometers and checked against standard thermometers.

"For high range thermocouples use is made of:

1. An electrically heated bath of metal of known melting point. (Used only for preparing standard couples.)
2. An electrically heated bath of pure lead for checking against standard couples.

Calibration

"For low ranges (0 deg. fahr. to 500 deg. fahr.), where great accuracy is required, the couples are checked every 25 deg. fahr. against a standard thermometer; the millivoltage in all cases being measured by a low range precision potentiometer, the cold end being maintained at 32 deg. fahr. with ice in a vacuum bottle. For all other ranges and where extreme precision is not required, readings are taken against a prepared standard every 50 deg. fahr. and the millivoltage developed is measured with a semi-precision potentiometer. The cold end here also is 32 deg. fahr.

"Indicators and recorders are checked against a semi-precision potentiometer at frequent intervals; this potentiometer in turn being checked against a potentiometer of high precision."

STATEMENT BY THE CLEVELAND ELECTRIC ILLUMINATING CO.

"The apparatus employed by this company in calibrating mercury-in-glass laboratory type thermometers is that shown in Fig. 2.

oil or solder in which the thermometers are immersed. Cylinder oil is used for temperatures up to 400 deg. fahr.; common solder is used above this temperature.

"Calibration is always against primary standard thermometers certified by the Bureau of Standards. Both ascending and descending calibrations are run, but in every case the temperature is held constant for five minutes during the period of readings at each point of calibration.

"Industrial type thermometers are not able to be calibrated in this comparator on account of the heat loss from the thermometer case. Instruments of this class are calibrated only under the actual conditions of use against laboratory type thermometers immersed in wells, inserted in the pipe or line as near the point of immersion of the industrial instrument as possible.

"Flue gas temperature instruments of the gas-filled type are calibrated against thermocouples. These are in turn calibrated against laboratory thermometers in a closed box in which is circulated heated air. Care must be exercised in calibrations of this kind to adequately shield the thermocouples and thermometers against radiation from the air heating elements."

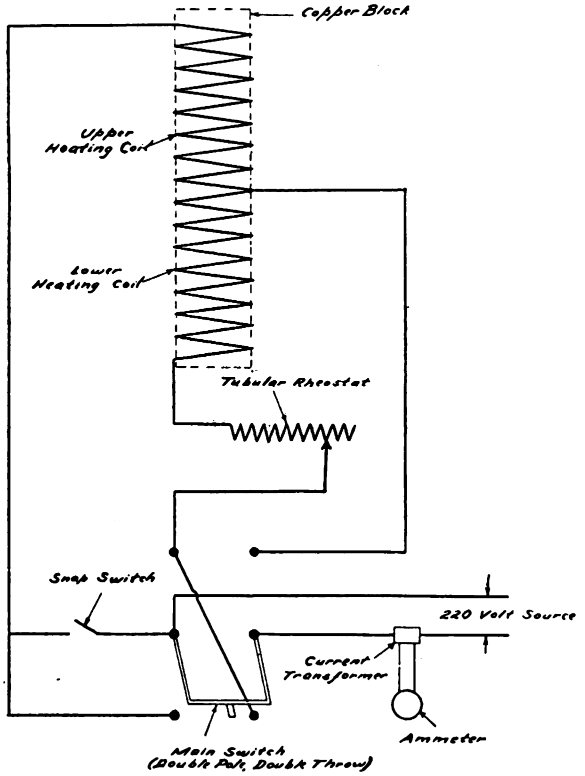

FIG. 4—WIRING DIAGRAM OF COPPER BLOCK THERMOMETER TESTER, PUBLIC SERVICE ELECTRIC & GAS CO.

Equipment and Method for Testing Thermometers

STATEMENT BY THE PUBLIC SERVICE ELECTRIC & GAS CO.

"In order to calibrate the various types of thermometers conveniently and accurately, the Testing Laboratory of the Public Service Electric & Gas Co. has designed and built one copper block thermometer tester and two test tanks suitable for use with either oil or water as a medium. All three testers are electrically heated from a 220-volt a-c. source.

"The copper block tester consists of cylindrical copper blocks 3½ in. in diameter and 1 ft. 9½ in. long. Five ⅞-in. and two ½-in. holes are drilled lengthwise through the block for inserting thermometers. The block is made in two sections, which are fastened together by means of dowel pins and a bolt through the center, as shown in Fig. 3. The block is mounted vertically on an iron frame and is surrounded with 3 in. of flaked asbestos, exposing only the holes at the top of the block.

"The wiring diagram for the copper block tester is shown in Fig. 4. Two heating coils, each consisting of 126 turns of No. 18 nichrome wire, are wound on the block, sheet mica be-

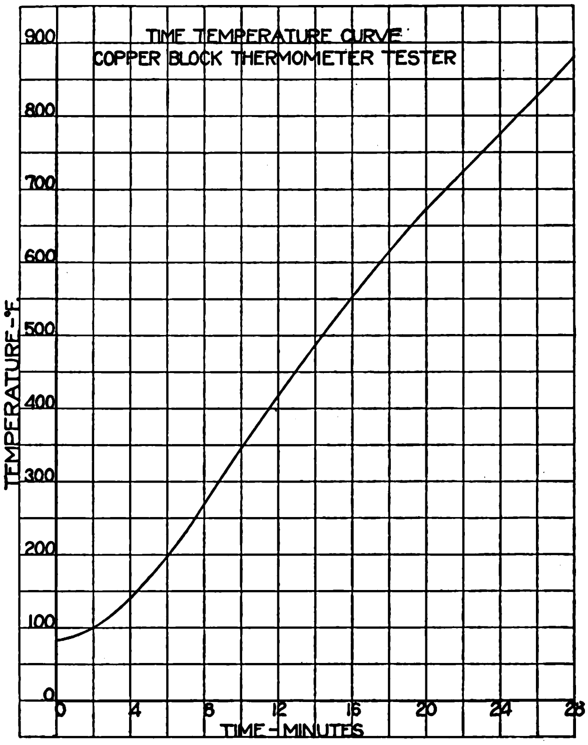

FIG. 5—TIME TEMPERATURE CURVE OF COPPER BLOCK TESTER, PUBLIC SERVICE ELECTRIC & GAS CO

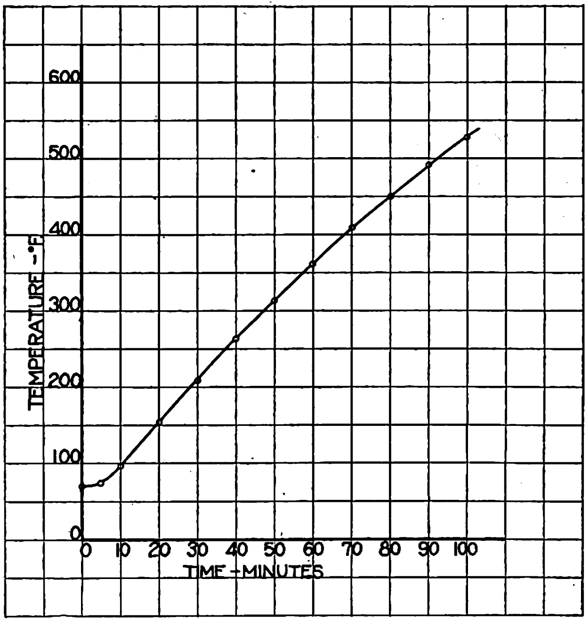

FIG. 6—Time Temperature Curve, Oil Bath Thermometer Tester, Public Service Electric & Gas Co.

ing used to insulate the coils from the block. When the double-pole, double-throw switch in the diagram is down, the two coils are connected in series; when the switch is up and the snap switch open, one coil is in service all alone; and when the main switch is up and the snap switch closed, the two coils are connected in parallel. By the above arrangement of switches and by adjusting the tubular rheostat shown in the sketch, the current may be varied from 1.3 amperes to 13 amperes, when connected to a 220-volt a-c. source. In the actual installation a special 6-point covered snap switch is used, taking the place of the double-pole, double-throw switch shown in the diagram. The time temperature curve, Fig. 5, shows that the temperature rises from 85 deg. fahr. to 650 deg. fahr. in 19 min. After the apparatus is once heated to the required degree, very little current is required to maintain the temperature. This equipment has been used for checking at temperatures as high as 1200 deg. fahr.

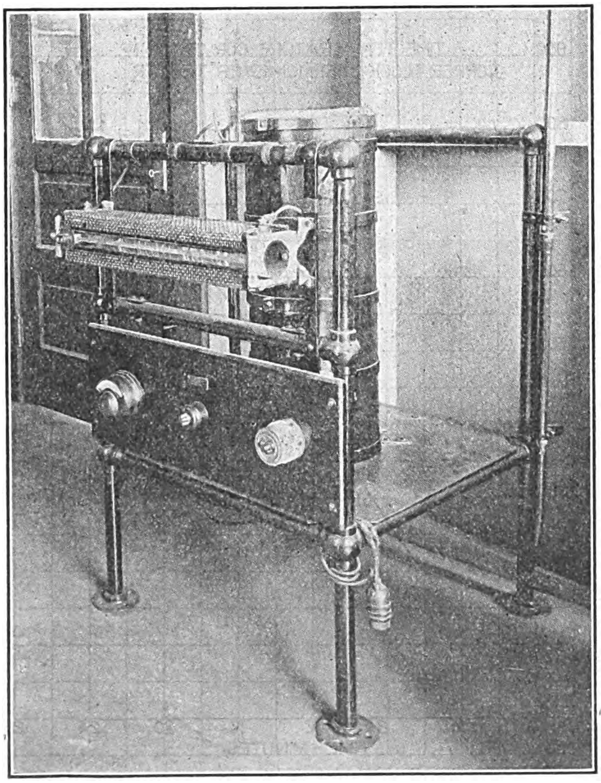

FIG. 7—Thermometer Test Equipment. Copper Block, Public Service Electric & Gas Co.

"Both the oil and the water bath testers have a brazed galvanized tank 7.75 in. in diameter x 1 ft., 6 in. in height, designed for holding oil at 600 deg. fahr. This tank is supported in a larger outer tank, and the space between the two filled with asbestos insulation. Both tanks are bolted securely to a heavy iron cover. The top of the inner tank is left open for inserting thermometers to be checked.

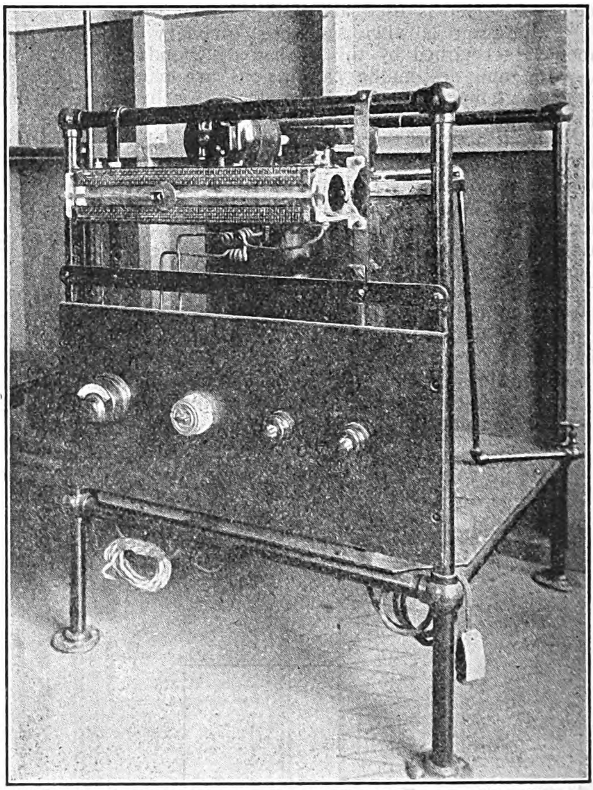

FIG. 8—Thermometer Test Equipment. Oil Bath, Public Service Electric & Gas Co.

"In order to obtain a uniform temperature throughout the bath, two impellers mounted on a vertical central shaft force the liquid down through an inner cylindrical tube and thence up along the heated surface of the tank, thus aiding the natural circulation. Holes in the upper end of the cylindrical tube allow the liquid to enter the tube above the impellers. The vertical shaft is driven through a worm gear by a ¼-hp., a-c. motor mounted on the top of the frame.

"The wiring diagram for the oil and water bath testers is the same as that for the copper block tester, shown in Fig. 4. Both heating coils, each having 69 turns of B. & S. No. 20 'Advance' wire, are wound on the outside of the inner tanks. This wire has a resistance of 287 ohms per 1000 ft. The time temperature curve, Fig. 6, shows the heating characteristics of one of these baths when filed with oil. The current consumed by each of these baths amounts to 13 amperes at 220 volts alternating current.

"Photographs of the copper block tester and of the two baths are shown in Fig. 7 and 8."

STATEMENT BY PHILADELPHIA ELECTRIC CO.

"Thermometers, according to their ranges, are tested in the laboratory by one of three comparators.

"The comparators and their ranges are:

	Range
1—Water bath	32 deg. fahr. to 212 deg. fahr.
2—Oil bath	212 deg. fahr. to 450 deg. fahr.
3—Lavite bath	450 deg. fahr. to 1100 deg. fahr.

Water Bath Comparator

"This comparator consists of a water bath tank made of copper. It is approximately 15 in. in diameter and 18 in. deep and is lagged with 1¾-in. thickness 85 per cent magnesia. The heat is supplied from a gas flame at the bottom of the tank. The water in the bath is agitated by introducing compressed air at a low pressure into the bottom of the tank by means of a ⅛-in. perforated ring which has a diameter of approximately 12 in. The thermometer indication is checked against that of a standard thermometer.

Oil Bath Comparator

"This bath consists of a vertical lagged tank 10 in. in diameter and 54 in. high. It is filled with oil commercially known as '600W,' which has a flash point of 700 deg. fahr. This oil is heated by means of heat generated in 24 electric resistors uniformly placed at the bottom of an 8-in. diameter tube. This tube extends up in the center of the tank almost to the top. Below the heating units is a motor-driven propeller, which assists in driving the heated oil up through the center tube to the top, where it flows over into the outer compartment and circulates down again to the propeller.

"The resistance units are connected in eight groups and the terminal wires from each group are so arranged externally to the heater that they may be connected in series or parallel, as desired. In this manner the current value can be controlled from 1 up to 80 amperes. The thermometers tested in this bath are also checked against standard thermometers.

Lavite Bath Comparator

"The third comparator is known as a 'lavite' bath, which consists of a steel pot approximately 8 in. in diameter by 24 in. deep, filled with lavite. The pot is heated by a gas furnace using a mixture of compressed air and gas. The pot is practically surrounded by gas flames except over the top. In this manner a more uniform temperature in the pot is assured. The thermometers checked in this bath are compared against standard thermometer or thermocouple indications.

"All standard thermometers and thermocouples have been certified by the Bureau of Standards at Washington.

"In all cases of checking, the thermometers are immersed to the proper depth and readings are taken after bath has been held at a constant temperature for a sufficient length of time to permit the thermometer to register a constant value.

"Thermometers are checked at various points as requested.

Lavite Bath Comparator

"In checking the various types of thermometers, the time required to reach a constant temperature depends upon the type being tested. The chemical type without any metal armor requires a minimum time of approximately 2 min., provided it has been previously heated to a temperature near the same value. Some of the commercial types equipped with metal armor require a much longer period of time to reach a constant value, as this time limit depends upon the amount of metal present which can radiate heat. In regard to this latter statement, some types have been checked where the amount of heat radiated by the thermometer armor was greater than could be supplied by a slow heating bath, so that the metal surrounding the thermometer bulb would never attain the temperature of the bath.

"In general, it may be stated that, if the circulation in a bath has sufficient velocity, a thermometer will reach a constant temperature in from 5 to 15 minutes, depending partly upon the amount of exposed metal armor and partly upon the difference in temperature between the room and the said armor."

Comparison of Water Flow Meters

STATEMENT BY THE UNITED ELECTRIC LIGHT & POWER CO.

"In an effort to determine the most satisfactory type of integrating and recording mechanisms for feed water service the United Electric Light & Power Co. installed several instruments connected to a common flow tube in a feed water riser supplying three boilers at Hell Gate Station.

"The instruments which were installed represented practically all of the generally used mechanisms from the standpoint of operating principle. There were three different types of recording and integrating meters.

1. Straight mechanical type using mechanical integration which is characteristic of the meters of this class.
2. Electrical type employing mechanical integration.
3. Combination of 1 and 2.

"The uniformity of flow through the feed water riser used for this test would be considered very good practice from a metering standpoint and conducive to accuracy in recording and integration as there were no pulsations in the flow or rapid and extreme changes of flow which often results in errors of metering.

"To further simplify the comparison, the peculiarities of the flow element itself were eliminated, since this is a problem of hydraulics rather than one of recording and integrating records. The problem in this instance was to determine which meter gave the most consistent record of the differential pressure in terms of water flow produced by the common Venturi tube under ordinary operating conditions. It has not been desirable to conduct a weighed water test on the installation for the reason that it was altogether too obvious that the instruments themselves were lacking in some important particular.

"The several meter manufacturers were each given a copy of the characteristics of the meter tube together with the maximum capacity required so that the instruments could be designed to record and integrate the water flow for the condition specified without any responsibility as to the accuracy of the meter tube. In other words, it was considered desirable to study the performance of the meter mechanism itself independent of the differential producing element. Past experience had indicated that the majority of the inaccuracies of metering were due to the mechanism, and that the differential producing element would at least give correct relative indications day after day, besides with water the Venturi tube or flow nozzle may be tested and

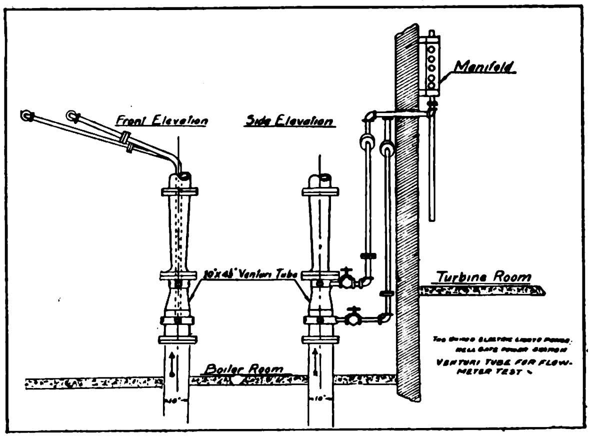

FIG. 9—VENTURI TUBE FOR FLOW-METER TEST, THE UNITED ELECTRIC LIGHT & POWER CO.

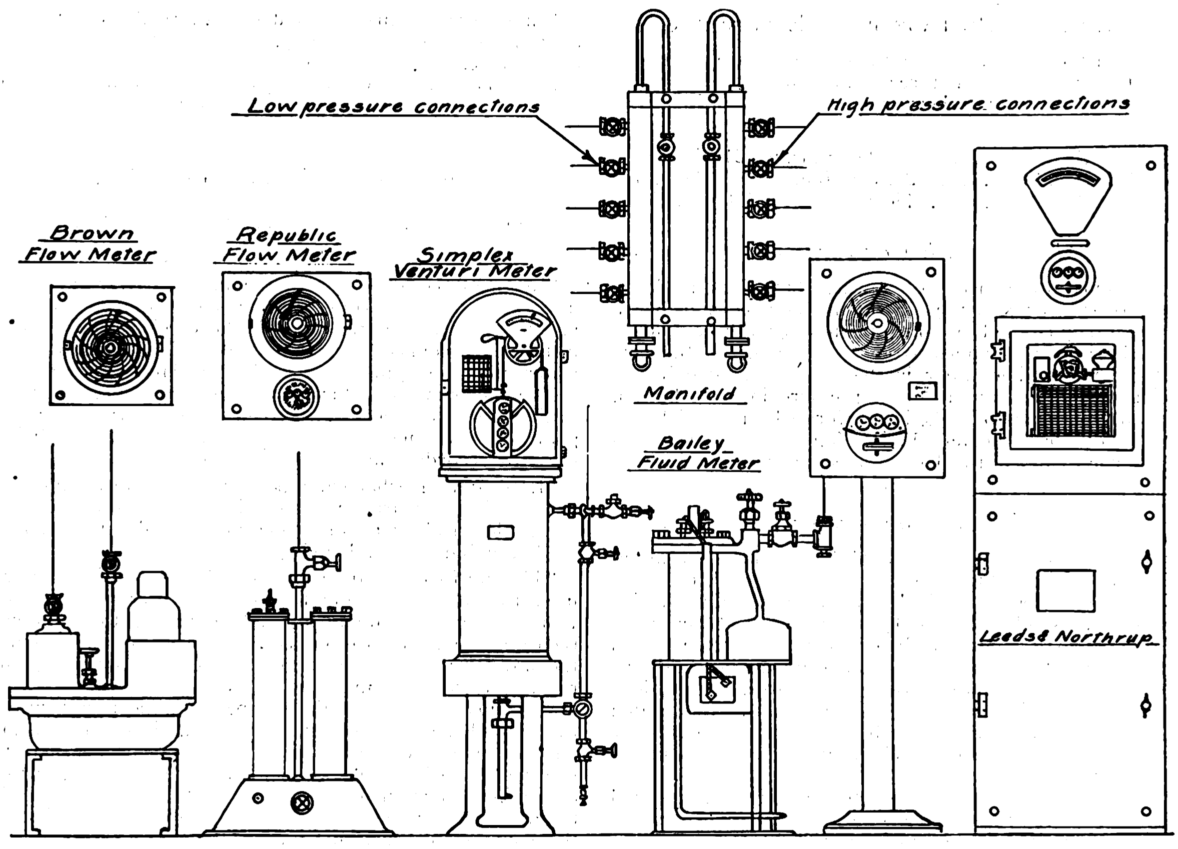

FIG. 10—ARRANGEMENT OF FLOW-METERS ON TEST, THE UNITED ELECTRIC LIGHT & POWER CO.

its characteristic determined with scientific precision. Once standardized, there is little likelihood of the nozzle or Venturi changing under ordinary conditions. The mechanism itself, however, is still subject to all of the ills indicated in this report.

"Instruments were selected for a capacity of 600,000 lb. per hr. which corresponds with a differential pressure of about 9 in. of mercury. It may be observed from the report that much of the time the instruments were operating at low capacity, which partially accounts for some excessive errors.

"The installation of the Venturi tube is shown in Fig. 9 and a group of meters, together with the manifold location, is shown in Fig. 10. The manifold was located higher than the Venturi tube, but this was not objected to by the manufacturers inasmuch as the tube was under high pressure which eliminated the possibility of air leakage into the system.

"The principal characteristics of the meters are as indicated in Table I. This table incidentally brings out in a striking manner the lack of uniformity of meter charts.

"The characteristic of the 10-in. Venturi tube with 4½-in.

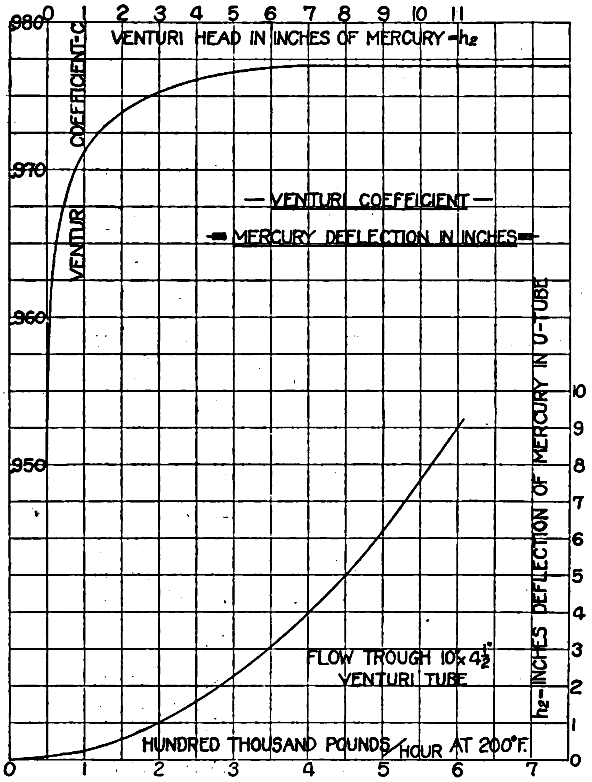

FIG. 11—Curve Showing Venturi Coefficient with Differential Head, the United Electric Light & Power Co.

throat is shown in Fig. 11. This curve also indicates the change in Venturi coefficient with differential head. While the coefficients are interesting in connection with hydraulic flow, this curve is of little significance in this particular installation, inasmuch as the United Electric Light & Power Company assumed the responsibility for the tube accuracy in order to eliminate this as a source of error or disagreement. The actual design data which was furnished the meter manufacturers is given in Table II.

Table II

Characteristics of 10 In. x 4.5 In. Venturi Tube 200 Deg. Fahr. Feedwater

[1] Water at room temperature above Mercury Legs.

"Varying coefficients are sometimes given as a cause of difficulty in meter installations, which is probably true in some instances, but in the light of our observations it appears that the larger part of the difficulties are caused by deficiencies in the recording and integrating mechanisms. Records of comparison between integrator and chart areas in terms of total flow are included to show the daily variations which exist. In spite of some fairly good monthly checks, some of the daily variations are excessive and would be decidedly misleading to the operating men who attempted to judge changes in operating conditions by records of this character. Although perfect agreement between chart and integrator record is not necessarily a measure of meter accuracy, it is one of the desirable characteristics of a good meter.

"In the light of our experience it appears that most meters are selected too large for the purpose intended, and that it would be better to select meters with a range which would be low enough so that for the majority of the hours of their use they would operate well out toward the upper end of their range with occasional peaks going beyond the chart range. This would necessitate a satisfactory seal to prevent loss of mercury at rates of flow beyond the range of meter, but it would seem to insure higher average accuracy.

"It might also be desirable to cut out the registration of the integrator and chart entirely when the pen drops within a few per cents of zero, depending largely upon the inherent amount of friction in the mechanism.

"During the time these instruments were under observation they received somewhat more expert and careful attention both on our part and the manufacturer's than should be expected under ordinary circumstances and a careful record was kept of the service requirements as well as the records and other observations. After the first installation some time elapsed before all of the meters could be made to operate with sufficient regularity so that their indications were worthy of comparison.

"In this report much of the preliminary difficulties are omitted, since this material would be too comprehensive to serve any useful purpose. Records of instruments which were replaced are also omitted where possible, since the information merely indicated at an early period that they were not worthy of the effort required to keep them in service.

"In the record of meter service the meter is identified by name but the comparison of the meter records is designated by letters; such as A, B and C. These meters have been in practically continuous service under operating conditions and the service requirements represent what might be expected in regular operation. The total flows as shown by the integrator by weeks and months from December, 1927, to September, 1928, inclusive is shown in Table III.

"A comparison of the total flow as shown by measuring the chart with that shown by the integrator for meters B and D shows the following differences based on the chart flow:

	Meter B Per cent	Meter D Per cent
April, 1928	—0.44	—5.80
May, 1928	+0.47	—2.30
June, 1928	+2.26	—3.41
July, 1928	—0.28	—1.58
August, 1928	+1.12	+1.77
September, 1928	+1.64	—1.95

"The importance of high accuracy and dependability of metering equipment in large scale power production can hardly be overstated. It seems reasonable to assume, however, that to secure meters with accuracy consistent with their importance, higher prices than we are now accustomed to pay may be necessary."

Recording Differential Pressure Gage, Developed from Type F12 (G. E. Co.) Bailey Flow Meter

Statement by Public Service Electric & Gas Co.

"For some time the need has existed for a differential pressure recorded suitable for obtaining a continuous record

of pressure drop ranging from 0 to 50 lb., such as, for example, might exist across boiler feed water regulating valves.

"At the present time there are several types of differential pressure regulating valves which are supposed to maintain a fixed pressure drop across the feed water control valve. This constant pressure drop tends to eliminate the hunting action set up by varying feed line pressure and changes in boiler drum pressure.

"In order to obtain a continuous record of the pressure drop across one of these feed water valves, thereby showing the action of the differential valve, it was found necessary to obtain a differential pressure recorder having a maximum differential of 50 lb. The Testing Laboratory of the Public Service Electric & Gas Co. conceived the idea of adapting a recording flow meter for this purpose and found that the Bailey mechanically operated meter (G. E. Co., type F12) would serve very well.

"A cross-sectional view of the type F12 flow meter is shown in Fig. 12. The high pressure side of a mercury U-tube supports an iron float which is geared by a rack and pinion to a cross shaft which carries a U-shaped permanent magnet. The magnet poles face toward the copper cap bolted over an opening in the meter body. The external mechanism of the meter has a shaft in axial alignment with the inner shaft and carries a similar magnet. By means of the two magnets the outer shaft is turned synchronously with the inner shaft, thus moving the indicating pointer, recording pen and integrating cam. The outer case of the meter contains the record chart and driving clock, also the indicating pointer, recording pen and integrating device. The integrating device may be removed when using the meter as a differential pressure recorder.

"As the differential pressure across the meter increases, the mercury and float are deflected downward in the inner chamber. The mercury displaced from the float chamber rises in the external chamber. The total differential pressure corresponding to a given depression of the mercury in the float chamber therefore varies in the ratio of the squares of the diameters of the float chamber and the external chamber.

"To adapt this type of meter for use as a differential pressure recorder it was, therefore, only necessary to change the diameter of the external chamber to one suitable for measuring the existing differential pressure.

"Three external chambers of different diameters were made from Shelby seamless steel tubing so that the meter could be used for maximum differentials of 15 lb., 30 lb. and 50 lb. The 15-lb. differential chamber has an internal diameter of 0.750 in., the 30-lb. differential chamber 0.498 in. and the 50-lb. chamber 0.364 in. The internal diameter of the float chamber is 2.0 in. Seamless steel tubing with an external diameter as near as possible to that of standard wrought-iron pipe was selected so that standard pipe fittings could be used. The new external chamber is connected at drain hole 'Y,' Fig. 13, the hole 'Z' being plugged.

"As a safeguard against loss of mercury in case the meter becomes overdeflected, a check valve containing a

solid iron ball float is installed above the external chamber. A collecting chamber is provided for any mercury which may blow by the check valve before the latter closes. Provision is made for returning any mercury collected in this chamber to the meter when conditions again become normal. The construction of the mercury check valve and collecting chamber is shown in Fig. 13.

"The differential pressure recorder charts in Fig. 14 and 15 shows the pressure drop across a Copes feed water valve with and without an excess pressure regulator controlling the pressure drop.

"Fig. 16 shows the installation of a differential pressure recorder across the feed water regulating valve of a boiler."

THE PRESENT STATUS OF METERING IN BLEEDER TURBINE STATIONS

In the metering of Bleeder Turbine Stations there appears still to be no very close standardization. Perhaps this is due to some extent to the lack of faith expressed by several members in the ability of flow meters now on the market to give and continue to give results anywhere comparable to weighing.

The Commonwealth Edison Co. makes an interesting statement in this connection which follows:

STATEMENT BY THE COMMONWEALTH EDISON CO.

"We do not have in any of our plants any complete metering system from which performance is computed.

"In our system we use the turbo-generating unit as our meter for steam consumption as we regard it as a better meter than anything else of which we know. Such a scheme involves knowing all the characteristics of the meter, or, in other words, the calibration must be known. This calibration, or water rate test is done at least once each year or oftener if any suspicion exists that the calibration has changed due to damage, etc.

"By the use of correction factors as supplied by the manufacturer and usually checked on the original guarantee tests (particularly the vacuum factor) we reduce our actual water rates, heat rates, thermodynamic characteristics, etc., over the desired load range to a set of standard conditions, usually the manufacturer's designed conditions but not necessarily so. In the case of the extraction cycle, the characteristics as to heat drops to each extraction point at all loads must be known.

"From our standard calibration, therefore, at the average load for the month the actual conditions are computed by use of the correction factors. The average conditions are those determined from the log sheets. We therefore have all the necessary data to obtain the actual steam supplied to turbine unit, the heat rate, extraction percentages, etc., from which the boiler room efficiency can be determined. Auxiliary steam, if any, is measured by the thermal method and is, of course, charged up to the particular unit using it. We make use of two kinds of boiler room efficiency. One is based on the quantity of heat actually delivered to the turbine and auxiliaries. The other is that based on the actual evaporation of the boilers. This one, of course, is higher, as it includes steam losses of any kind avoidable or unavoidable. The efficiency based on delivered heat is the one that means the most from the viewpoint of overall station performance. The other one is a better gage of the actual performance of the boiler room separately.

"The calculation of the boiler room evaporative efficien-

cies involves knowing make-up, blow-down, drainage and other conditions obtained by meters and check-ups.

"The general method as above outlined does involve careful calculation, as would be expected, and the use of the results relatively give us the trend of our conditions which, after all, is mainly what is wanted. We have no difficulty in finding the 'bad spots' from our final analyses. In our case we have five large stations to check. It takes the time of one man about one week out of each month to calculate these summaries. On the other hand, we have no expensive metering system.

"In such a system as we use it is readily admitted that certain small errors from an absolute viewpoint are probable, but fortunately they are relatively small in per cent and in addition concern mostly conditions that are only of small effect as well. In order to verify our method from a practical standpoint we have taken a unit at Crawford Avenue, running with reheat, three stage extraction and some auxiliary steam. The unit was operated for a period involving all usual operating conditions. From the hourly log readings and the use of the test data characteristics the water rate was calculated to be 9.574 lb. The actual weighed water was 9.650 lb., or an error of less than 0.8 per cent, part of this difference explainable by a slight heater leakage which allowed of recirculation. If in such a heat cycle there existed any appreciable heater leakage it can be readily seen that meters would be useless, whereas the effect on the calculated steam consumption would be negligible from any practical standpoint."

The Committee would point out that the above method appears to assume a straight Willans' line for the turbines and therefore must be in error if the overload valves are open from any appreciable time during the period considered.

In general, however, most members depend upon flow meters of some sort to keep a check upon turbine performance. Two members, out of the eleven replying, use steam flow meters at the turbine throttle, but in most cases the turbine steam consumption is determined by condensate measurements.

Frequently the bleeder heater drips are not measured separately, nor are they included with the condensate meter. In some cases they are merely estimated and in others they are included with the boiler feed meters or dischargd into the condenser.

In the boiler room the general practice seems to be at least to meter the flow to the individual boilers with the addition in some cases of the total boiler feed. This addition makes one group of meters check another and the idea is used by one company to work up a balance sheet for the meters.

Boiler blow-downs are about the only losses of which any attempt is made to obtain a record. Where this is done it is by the V-notch weir meter.

Weigh larries and automatic scales give record of coal to individual boilers.

Fig. 17-18-19-20 and 21 are the connection diagrams of several stations in which the locations of instruments are shown.

It is becoming a more general practice to keep a check upon station operation by comparing periodic results with some form of "bogey," as is illustrated in the Report of the Prime Movers Committee entitled "Power Station Betterment" (Pub. No. 278-101, September, 1928). Half of the replies received report use of the "bogey," while others merely make daily, weekly and monthly tabulations of operating results which are compared with each other to show the trend.

MANUFACTURERS' STATEMENTS

The Prime Movers Committee Does Not Accept Responsibility for Any Manufacturers' Statements

STATEMENT BY BAILEY METER COMPANY, CLEVELAND, OHIO

Remote Recorders and Indicators

"This company is now in a position to supply equipment for recording and indicating pressure, temperature, draft, liquid level and other factors at practically any distance from the source. In fact, any condition which can be measured can be recorded and indicated at the desired distant point through the use of the mechanism now made available by this company. Positive and accurate transmission of measurement is assured.

"The elements used for measuring pressure, temperature, etc., at the source, are standard equipment, having been in service in power plants for years. For the transmission of the measurements, the Selsyn motor is used. This is the device which for some time has been in service on battle cruisers, for the direction of gunfire from the bridge, and in practically every central station for the transmission of signals from the control room to the operators. A unit for indicating draft is shown in Fig. 22.

"The Selsyn system consists fundamentally of a Selsyn motor and a Selsyn generator which are in some respects like three-phase induction motors, but have shuttle-wound rotors with definite poles whose windings are connected through slip rings or flexible leads, depending upon the type of construction, to a single-phase, a-c. source of excitation. Their stators are inter-connected electrically.

"The generator is commonly called the transmitter and is rotated by the device measuring the factor to be transmitted. The motor is installed at the remote point and is connected to the indicator or recorder.

"When the supply circuit is closed an alternating voltage is impressed on the rotors and, as the motor or receiving rotor is free to turn, it takes a position corresponding to the position of the generator or sending rotor; and, if the sending rotor is turned, the receiving rotor follows at the same speed and in the same direction.

"The reason for this synchronous operation is that the single-phase current in the rotors induces voltages in the three legs of the stators. The three voltages are unequal and vary with the positions of the rotors. When the receiver rotor is in exact correspondence with the transmitter rotor, the voltages induced in the receiver stator are equal and balance the voltages induced in the transmitter stator so that current does not flow in the stators (secondary circuits).

"If the receiver is restrained from assuming the same position as the transmitter, the induced voltages are no longer equal and balanced, and current flows in the stator circuits. This current reacts upon the rotors and sets up a torque which tends to bring them into agreement. If the transmitter is held, the torque reacts against the force which restrains the receiver, thereby tending to bring it into correspondence with the transmitter.

"Selsyns are exceptionally accurate because of the shuttle-wound rotors, careful balance of electrical and mechanical parts and low friction ball bearings. The receiver responds immediately to the position of the transmitter. There is no hesitation in starting. The transmitter moves and the receiver follows instantaneously. If power fails, the receiver automatically resets in agreement with the transmitter on resumption of power. Several receivers may be operated from the same transmitter.

Up-to-Date Boiler Control Panels

"Modern power plant practice requires that the operating guides and control equipment for each boiler be centralized on a neat-appearing compact panel conveniently arranged so that the operator can grasp operating conditions instantly and, if changes are required, make them without loss of time. Bailey meter equipment lends itself very well to these requirements as illustrated in Fig. 23.

"The panel shown in this illustration contains at the top a 12-compartment, Multi-Pointer Gage indicating drafts and pressures which are necessary to correct operation, but not essential as a matter of record. The flush front recorders at either side of the panel record Flue Gas Temperature and Air Temperature at the inlet and outlet of the two air preheaters. The recorder at the left of the twin flush front mounting in the center of the panel records and indicates Steam Flow from the boiler, records Air Flow and also Superheated Steam Temperature at the outlet of No. 1 superheater. The meter at the right of the twin flush front mounting records and integrates Feed Water Flow, Steam Temperature at the outlet of No. 2 superheater and Reheat Steam Temperature at the inlet and outlet of the reheaters.

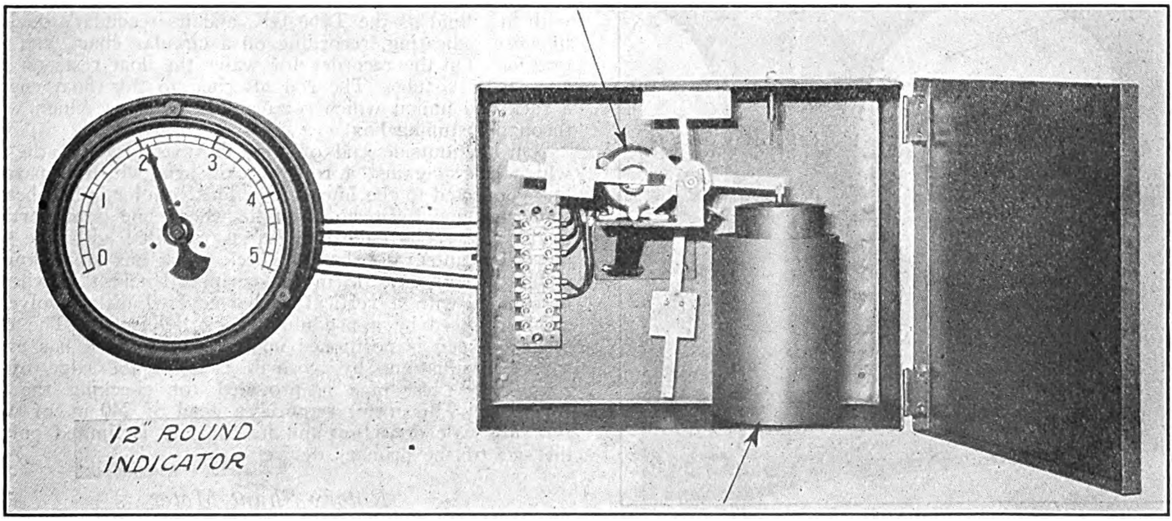

FIG. 22—LONG DISTANCE DRAFT INDICATOR, BAILEY METER CORP.

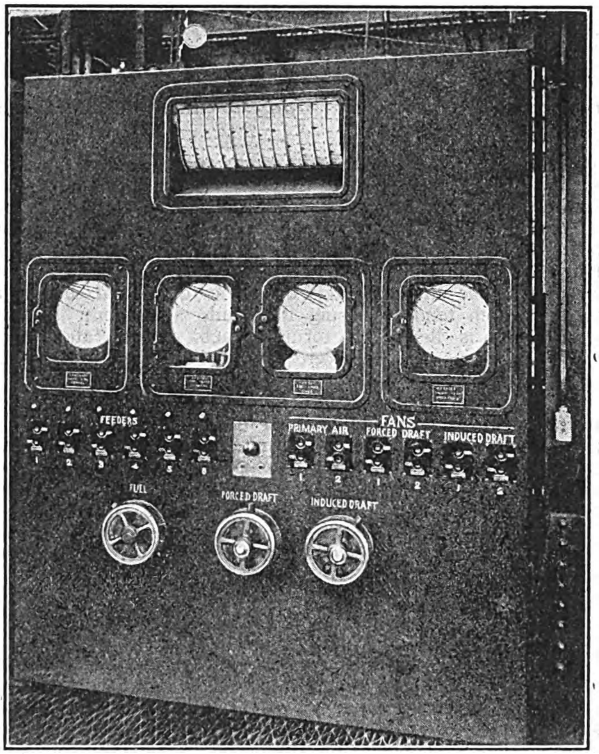

FIG. 23—BOILER PANEL—1300-LB. BOILER, LAKESIDE PLANT, MILWAUKEE ELECTRIC RAILWAY & LIGHT CO., BAILEY METER CO.

"Below the metering equipment are mounted the stop and start buttons for the feeder motors and fan motors, the automatic control system drum switch and the hand wheels for controlling the fuel, forced draft and induced draft manually, in case this procedure is necessary.

"The drum switch at the center of the panel is designed to permit push button control of induced draft, forced draft and fuel separately or together, depending on the point to which it is turned. The final switch position connects the boiler to the automatic control system.

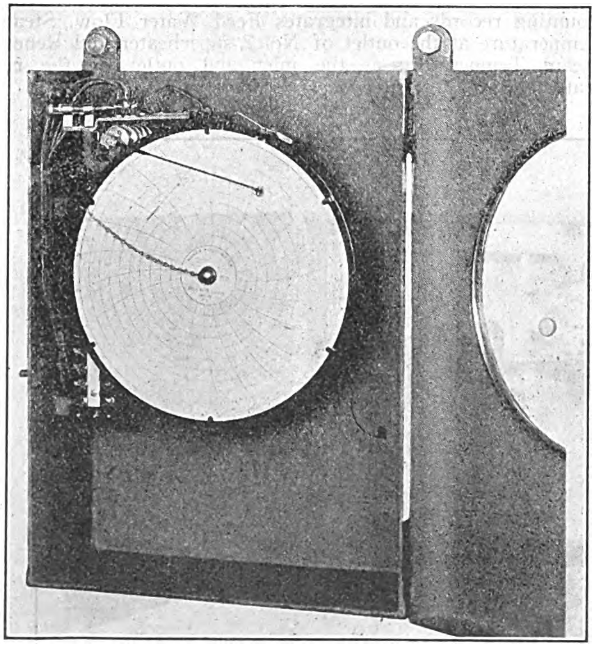

FIG. 24—SPECIAL LIQUID LEVEL RECORDER DESIGNED TO OPERATE SIGNAL LIGHTS AND PUMPS, BAILEY METER CO.

Special Liquid Level Recorders

"Fig. 24 shows an interior view of a specially constructed liquid level recorder used on a 25,000-gal. water tank. The mechanism is designed to give a record of water level on a 12-in., 24-hr., circular chart and also operates mercoid switches to sound alarms at predetermined maximum and minimum water levels. In addition, mercoids are operated to start pumps to fill the tank as the water passes the ¾-full point on a decreasing level and to stop the pumps at slightly less than full tank level.

High-Pressure Meters

"Keeping step with the tendency of modern power plant design toward the higher pressures, this company has designed and built Steam Flow Meters for operation on pressure up to 1500 lb. per sq. in. One of these meters has been in satisfactory operation over a period of about four years and several more have been in operation approximately one year."

STATEMENT BY THE BUILDERS IRON FOUNDRY, PROVIDENCE, R. I.

Diaphragm Meter, Type GK, Register-Indicator-Recorder

"This instrument employs as a primary device an orifice, nozzle or Venturi meter and its secondary device is indicating recording on a circular chart and integrating. The formed double conical diaphragm is held in position by two springs. The left-hand spring has a nut for zero adjustment on the outside of the case. A small roller rests against the diaphragm plate and is mounted on a crank arm which actuates the main shaft of the indicator hand. A small cam locates the pen on an evenly spaced chart. A guard on the pen shaft holds a pawl out of contact with the teeth of a circular rack, and this pawl is moved through a cycle at regular time intervals by a Warren electric clock. The rack actuates a direct-reading counter. The diaphragm casing contains water and this meter is used generally on steam and water. This meter is not affected by extreme overloads, requires a head of 60 in. of water for full scale deflection and its capacity is limited only by the size of the primary device.

Type "Y" Register Indicator Recorder

"This instrument has the same range of primary devices with any fluid as the Type GK, and its secondary device is likewise indicating, recording on a circular chart, and integrating. On the recorder for water the float rests on mercury in a U-tube. The rod attached to this float engages a rack and pinion which rotates a small shaft which works through a stuffing box.

"On the outside end of this shaft is attached the cam which bears against a roller on an arm which is parallel-link connected to the integrator. This counter is ball-bearing supported and twists to an angle whose sine is proportional to the rate. The indicator dial is graduated with sine spacing. The integrator has a wheel which has small knurled rollers whose axes form the periphery, and this wheel is in contact with a vertical rubber-covered disk revolved at constant speed by a pendulum clock movement. The chart recording pen is positioned upon a chart which has evenly spaced graduations by a small cam on the edge of the counter. A test pipe is provided for checking the performance. This meter requires a head of 240 in. of water for full scale deflection and its capacity is limited only by the size of the primary device.

Rotary Shunt Meter

"In this instrument the revolutions per minute of the damped turbine vary as the square root of the head, and consequently the usual orifice formula and density corrections can be used. Also, the water damping greatly reduces the turbine speed. The turbine speed then depends only upon the head and thus this is not simply a proportional meter in which the turbine speed is proportional to the velocity but a true differential type meter.

"The turbine shaft speed is gear reduced and transmitted by permanent magnets without a stuffing box, to the counter. The size of orifice and the gearing make the counter direct reading for any given conditions. This unit is used for gases and steam in 2-in., 3-in. and 4-in. sizes. Larger size mains are metered by installing the 2-in. meter in a by-pass around a standard orifice with pressure connections as usual at one diameter upstream and at the vena contracta. Pressure connections are provided at the shunts' inlet and outlet so that a simple chart rate recorder can be attached if desired. This meter requires a head of 80 in. of water for full scale deflection and can be used with steam, gas or air.

Builders' Standard Orifice Flanges

"A thin-edged orifice is used between flanges containing the pressure connections. This form is exactly reproducible and any imperfections which would effect the differential can be readily detected by visual inspection.

"A thick, amply strong plate is used; the upstream edge is square and sharp while the trailing edge is beveled so that the working edge of the orifice is relatively thin.

"The flange connections make the coefficient as nearly independent as possible of roughness and variations in pipe size. The annulus permits accurate results to be obtained in spite of rivets or other irregularities near the orifice. The independent pressure connection is used near an elbow, for example, or when it is desired to use a non-circular orifice plate to measure very large flows. Since the connections are in the flange they are of ample size to use with powerful registers and are especially good where pulsating flow occurs. Due to accurate machining, the orifice can be exactly centered. When inserting another orifice it is not necessary to disturb the pressure connections at all."

STATEMENT BY COCHRANE CORPORATION, PHILADELPHIA, PA.

"The Cochrane Flow Meter and the Cochrane V-Notch Meter have been on the market for a number of years but several improvements in the integrating mechanism made during the past year have not before been described in any publication.

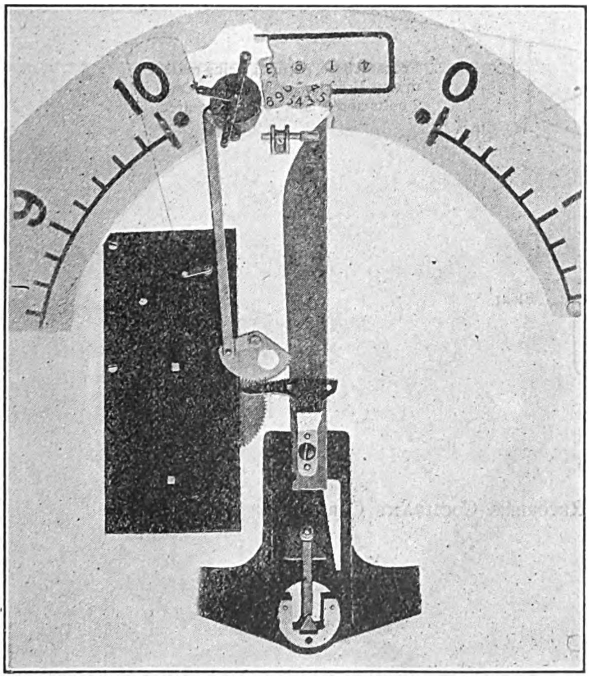

FIG. 25—INTEGRATOR OF COCHRANE FLOW-METER WITH DIAL HAVING EASILY READ FIGURES, COCHRANE CORP.

"One of these is the direct reading integrator shown in Fig. 25. The Flow Meter integrator is of the direct reading type, that is, the figures are read off directly as they appear, eliminating the possibilities of error which are inseparable from the 'gas-meter' type of counting train. With the Cochrane type of counting train only the figures which ought to be read are visible.

"The integrator itself is positive and mechanical in action and does not depend upon secondary forces, such as electrical current, magnetic attraction or sliding friction, nor is the transmission of motion affected by vibration or chattering or by other outside disturbances such as variations in voltage.

"A crank on the clock by means of a flexible link drives an oscillating lever back and forth in such a manner that the lever moves the counting train forward a distance corresponding to the instantaneous position of the U-tube balance. This is accomplished by a pawl on the oscillating lever, which engages with a disk mounted on the units spindle of the counting train. The engagement of the pawl is controlled by an integrator cam, the position of which is determined by the position of the U-tube balance, while the release of the pawl is controlled by the permanent 'knock-off point,' which is properly adjusted when the meter is calibrated in the shop. When the pin on the pawl reaches the release point of the cam, the pawl grips and moves the disk forward. On the return stroke, the pawl rides over the disk without moving it. Due to its peculiar shape, the pawl acts as a wedge in moving the disk forward and slippage does not occur, but continued high accuracy is obtained after long use. This form of integrator imposes no load upon the deflecting member and, therefore, does not affect in any way the accuracy of the latter.

"In the V-notch integrator, shown in Fig. 26, a roller carried by the float stem moves up and down in a straight line. This roller bears against a cam suspended from a pivot approaching the pivot at the higher rates of flow. The cam is so shaped that it is rotated through equal angles for equal increments in rate of flow. The pen arm is attached directly to the cam spindle and the pen inscribes upon a circular chart having equal divisions. The rotation of the cam also operates through a linkage a pointer which moves over a scale having equal divisions. A sector attached to the cam spindle moves the stop of a clock-operated integrator, consisting of a counting train which is periodically advanced in proportion to the momentary rate of flow. The cam is held against the roller on the float stem by a counter weight. All parts of the translating mechanism are slow moving and no harm results from sudden up or down movements of the float. Where the meter is used with hot water which undergoes rapid fluctuations in temperature, the float is placed in an outside float chamber communicating with the weir chamber through a narrow vertical channel, which insures the correct water level in the float chamber irrespective of differences in density between float chamber and meter chamber. The water in the float chamber remains, in general, at a temperature lower than that in the meter chamber, thus reducing the tendency to flash upon sudden reduction of pressure."

STATEMENT BY THE FOXBORO COMPANY, FOXBORO, MASS.

New Instrument

"The design of the new Foxboro Steam Flow Meter, Fig. 27 and 27a, is based on that of the Foxboro Orifice Meter, which has been extensively used for many years for the measurement of gas flow under field conditions where a rugged simple mechanism of high precision is necessary.

"The instrument is calibrated to read and record in terms of flow and is equipped with a simple and dependable integrator that reads direct without multipliers the total pounds of steam that have passed through the pipe. The chart reading is direct in lb. per hr.

"This new meter is fundamentally accurate because it is of a simple mechanical design in which friction is reduced

to a minimum and a large, powerful float is employed, the motion of which is transmitted without angularity (harmonic motion) and because the coefficients were carefully determined by us after extensive research and experimentation covering a period of years.

"The hook-up of the meter with the pipe line is extremely simple. The use of separate sediment and condensate chambers has been eliminated by employing only a single chamber of unique design that serves both purposes.

"The new meter is a single unit. It has no electrical devices, special compensators, balances or stuffing boxes; and requires no maintenance except to blow the drip, change the chart and ink the pen.

Improvements

Pivoted Pen-Arm Movement

"The difficulties encountered in the construction of multiple-pen instruments have always been to make the brackets rigid enough to support the pens properly in front of the chart and to get the pens to follow accurately the predetermined arc of the chart. Our new Pen-Arm Movement, Fig. 28 and 29, absolutely overcomes these difficulties because each pen arm is pivoted at its center of motion in a firmly fixed plate above the chart disk.

"The pens move on the same fixed center of rotation and produce accurate records throughout the scale. Time differences between pens are minimized. Inking, cleaning and replacing pens are simplified. The new movement makes Multiple-Pen Instruments as practical and accurate as the Single-Pen.

New Chart Hub

"The new Foxboro Push-Button Chart Hub has all the special features associated with its predecessor. It accurately centers the chart. There are no threads or complicated mechanisms. A slight push of the tension head snaps it into position where it grips the chart securely in place. Simply twisting the head to left or right turns the chart to the correct time adjustment. It is no longer necessary to remove the chart holder.

"The latest improvement lies in the ease with which it can be detached. With the holder between the first and second fingers, the operator has simply to press the button under his thumb and the chart is released. There is no tugging or jerking of the chart hub, no strain on the clock spindle.

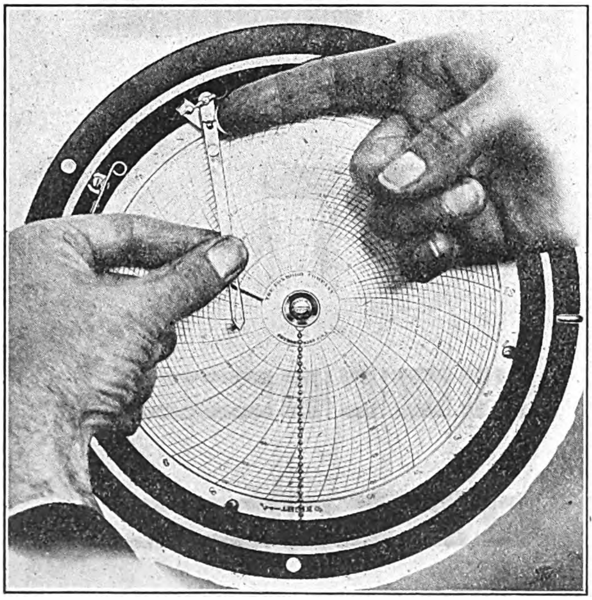

FIG. 30—DETACHING PEN ARM, FOXBORO CO.

Detachable Pen Arm with Open End

"The latest improvement in Foxboro Recording Instruments is the patented, Detachable Pen Arm with Open End (Fig. 30 and 31). It can be quickly replaced if bent or broken. All one has to do is to detach the pen arm with the finger nail and slip on a new one. The insert shows the simple construction of this pen arm and how easily it can be slipped into place.

"The lower end of the pen arm is open to facilitate the removal, cleaning and inking of the pen and to keep the pen arm clean."

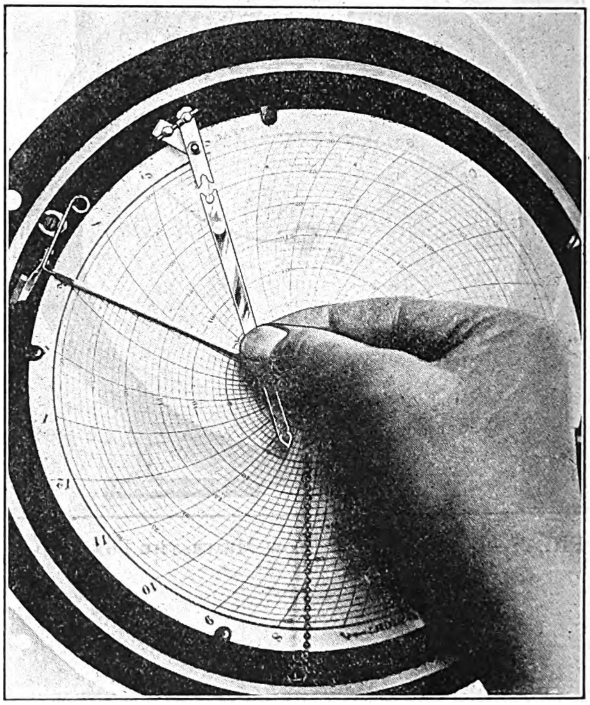

FIG. 31—REPLACING PEN ARMS, FOXBORO CO.

STATEMENT BY THE CAMBRIDGE INSTRUMENT COMPANY, INC., NEW YORK, N. Y.

"We have recently developed a new instrument known as the Cambridge Dissolved Oxygen Recorder for accurately measuring and recording the proportion of oxygen in feed water entering the boiler. A small quantity of water from the feed water system is passed at a constant rate through a tower filled with extractor rings where it is 'scrubbed' by a constant flow of pure hydrogen generated electrolytically. The hydrogen mechanically displaces the dissolved oxygen in the feed water, and the relative rates of flow of hydrogen and water are so arranged that the displaced gas forms a considerable percentage of the total gas issuing from the top of the scrubber. This percentage is measured by means of a katharometer and is shown on the chart of the recorder.

"The katharometer contains two identical spirals of platinum wire, inclosed in separate cells in a metal block, the spirals being connected to form two arms of a Wheatstone bridge circuit. When an electric current flows in the circuit, the spirals become heated and lose heat to the walls of their cells, their temperatures and, in consequence, their resistance depending on the thermal conductivity of the gases surrounding them. One of the cells is exposed to the pure hydrogen passing from the electrolytic supply, while the other cell of the katharometer is exposed to the gas after passing through the scrubber tower. Owing to the presence of the oxygen from the feed water, the thermal conductivity of the gas in the second cell of the katharometer is different from that of the first; and the Wheatstone bridge circuit is thrown out of balance, causing a deflection of the galvanometer, the extent to which is an indication of the amount of oxygen present in the second cell.

"The katharometer is connected by 4-way leads to a standard thread recorder of the type supplied by us for many years in connection with gas analysis instruments. The recorder is entirely clock-driven and consists of a moving coil galvanometer the pointer of which is automatically depressed once a minute on to an inked thread which it presses into contact with a moving chart. A continuous record is thus obtained in the form of closely spaced dots, pen friction being entirely avoided. The record for the past few hours is always visible, while the actual percentage of dissolved oxygen at any moment can be read on an engraved scale fixed over the pointer. The complete mechanism is inclosed within a robust, dust-tight, metal case which can be easily fixed to a wall or other support."

STATEMENT BY THE PERMUTIT COMPANY, NEW YORK, N. Y.

The Ranarex CO_2 Recorder

"The use of Ranarex CO_2 recorders in connection with boilers burning gaseous fuel has revealed some very interesting facts. The Ranarex principle is based on the fact that the specific weight of flue gas increases in proportion to its CO_2 content, CO_2 being about 50 per cent heavier than the other constituents of the flue gas. When insufficient air is supplied to a furnace the combustion is incomplete and with solid or liquid fuels the incompletely burned matter is mainly CO and soot. The soot is filtered out before the gas sample is analyzed; CO has the same specific gravity as nitrogen so that it does not appreciably affect the accuracy of the Ranarex recorder, which will therefore indicate the actual CO_2 percentage. In such cases the Ranarex indicates an oversupply of air by a low CO_2 reading and a deficiency in air supply can be recognized by too high a CO_2 content and, usually, by the appearance of smoke.

"When burning gaseous fuels, however, with a deficiency in air supply the unburned or incompletely burned matter consists of CO, hydrogen and hydrocarbons, the CO percentage usually being quite low. Therefore it is not possible to determine a deficiency in air supply by means of an ordinary Orsat apparatus, nor is it always possible to recognize it by observing the stack, since incomplete combustion of gas may take place without resulting in any appreciable amount of smoke. The determination by chemical methods of the hydrogen and hydrocarbons in the products of combustion requires complicated apparatus, not very suitable for use in a boiler house. However, the presence of these gases is clearly indicated by the Ranarex CO_2 recorder. Hydrogen and hydrocarbons are much lighter than air and reduce the density of the flue gases to such an extent that the Ranarex gives a low reading and may even have a tendency to indicate negative values.

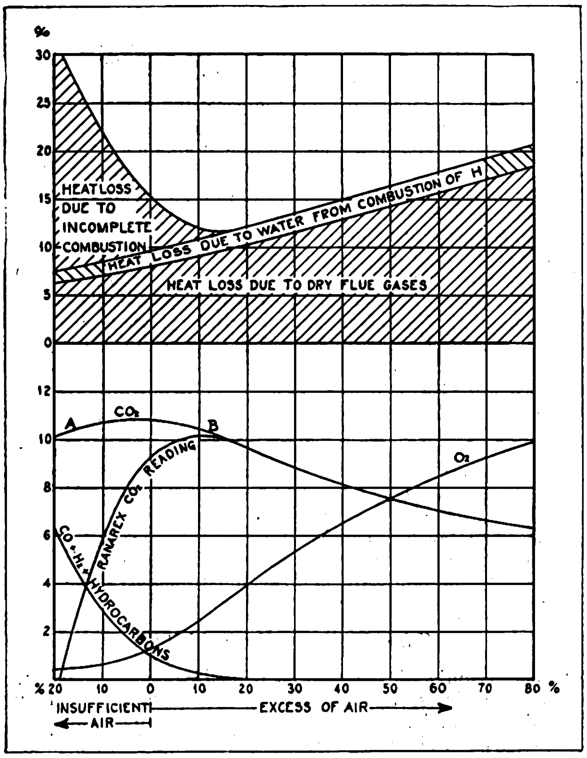

FIG. 32—THE RANAREX COMPANY, CO_2 RECORDER CURVE, THE PERMUTIT CO.

"In Fig. 32 the conditions are illustrated such as take place when natural gas, consisting chiefly of methane, is used as fuel. The lower part of this diagram shows the flue gas analysis and the reading of the Ranarex recorder. In the upper part of the diagram the stack losses have been plotted, the total stack loss consisting of the heat loss due to the heat content of the dry flue gases, the heat loss due to water formed by combustion of the hydrogen and the heat loss due to incomplete combustion.

"It can be seen from this diagram that the minimum total stack loss, corresponding to maximum boiler efficiency, just about coincides with the maximum reading of the Ranarex recorder. Whenever the Ranarex reading is low this is due to excess of air or insufficient air being supplied to the furnace. However, if the fireman cuts down the air supply in order to raise the CO_2 content and then finds that the Ranarex reading drops further, he knows immediately that he is not admitting enough air and he will therefore be able to take the proper steps to adjust the air-fuel ratio so as to result in maximum efficiency. Since there is no time required for chemical reactions and since the Ranarex draws the gas sample through the pipe line at a high rate of flow, the time lag is very short and the firemen have no difficulty in quickly adjusting the air supply to the correct value by using the Ranarex machine as a guide.

"In conclusion, where natural gas is the fuel employed and a hand operated or automatic Orsat apparatus is used to determine CO_2 and CO, the operator is easily misled by high CO_2 (see section A-B of the CO_2 curve) and low CO readings into assuming that the combustion is fairly complete and efficient; whereas in reality the amount of air supplied may be deficient, resulting in immense heat losses due to the presence of unburned hydrogen, methane and other hydrocarbons in the flue gas not detected by the Orsat. By using the Ranarex recorder instead of the Orsat, the operator is provided with an instrument which detects readily and positively the presence of these unburned constituents of the flue gas and he is, therefore, in a position to prevent the high heat losses due to incomplete combustion, as well as those due to an excess in air supply.

The Ranarex Gas Density Recorder

"A Ranarex density recorder (see Fig. 33) has been developed, which operates on the same basic principle as the Ranarex CO_2 Recorder. When gas is metered by means of an orifice meter, it is necessary to know the specific gravity of the gas in order to determine the quantity passed through the meter. In such cases the Ranarex gas density recorder will be found very useful.

"The practice of mixing different types of gases is coming more and more into use. Variations in the specific gravity of the mixed gas are undesirable since they interfere with satisfactory operation of the gas burners. Such variations can immediately by detected and, therefore, prevented in time by the use of a Ranarex density recorder."

STATEMENT BY C. J. TAGLIABUE MFG. COMPANY, BROOKLYN, N. Y.

"There have been no radical changes in our regular line, which is constantly subjected to detail improvements. The most important development is that of a fully-compensated, mercury-actuated recording thermometer, permitting the use of connecting tubes up to 150 ft. in length (previously 25

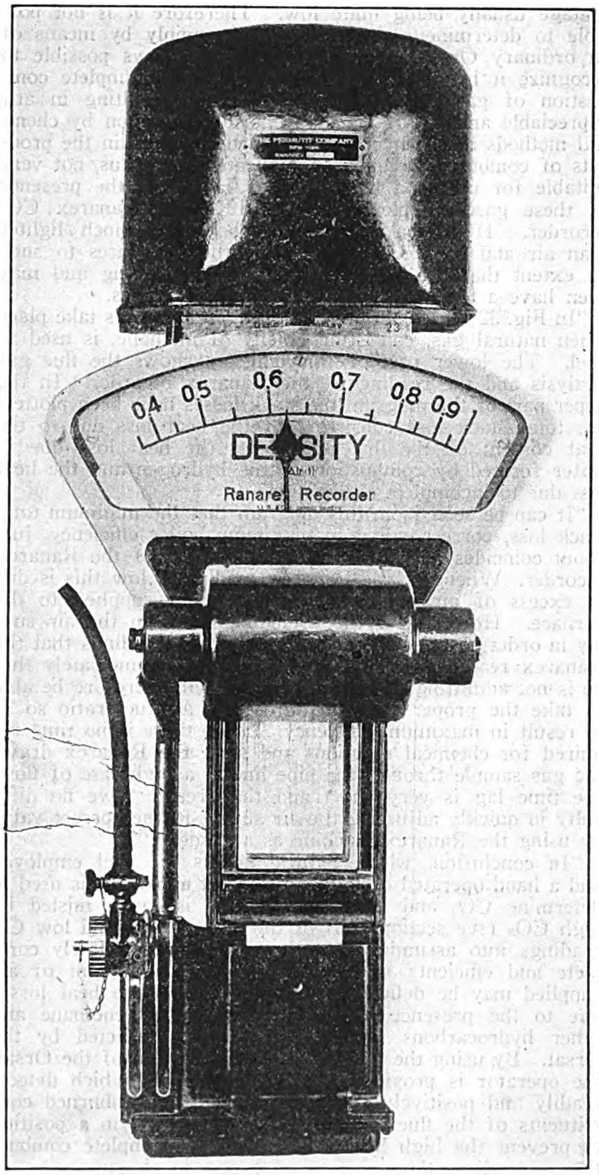

FIG. 33—THE RANAREX DENSITY RECORDER, THE PERMUTIT CO.

ft. had been the limit for this type of instrument of all makes), with no possibility of inaccurate readings even should the connecting tube be laid alongside of a boiler or of a refrigerating room."

STATEMENT BY CONSOLIDATED ASHCROFT HANCOCK COMPANY, INC., AMERICAN SCHAEFFER & BUDENBERG CORPORATION DIVISION BROOKLYN, N. Y.

"Among outstanding developments in the art of manufacturing the expansion type recording thermometer should be mentioned a new steel capillary tubing we have introduced during the year. This steel tubing has a bore of 0.008 in. to 0.011 in., as against 0.023 in. for the tubing used in the past. The result of this improvement is that we are now able to furnish mercury-actuated recording thermometers with lines 100 ft. long and guarantee them accurate within 1 per cent of the scale range. The invention, therefore, has greatly broadened the field for mercury-actuated instruments, which must be preferred to all others because of the uniform characteristics of mercury, the large amount of motive power of the mercury system and the great mechanical strength and durability of the welded steel systems, which are used in mercury-actuated thermometers."

STATEMENT BY THE BROWN INSTRUMENT COMPANY, PHILADELPHIA, PA.

Resistance Thermometers

"Resistance thermometers manufactured by the Brown Instrument Company recently have been redesigned and improved. Equipments requiring the measurement of temperature in more than one place are furnished with a bridge circuit box wherein each thermometer bulb has an individual bridge circuit, thus eliminating any switching or poor contacts in the bridge circuit proper. The switching is done in the galvanometer circuit which is high enough in resistance so that no appreciable errors will be introduced.

"Indicating instruments, recording instruments, or both, can be arranged to indicate or record the temperature of the same bulb, and as many as twelve bulb temperatures can be recorded on the same instrument. Instruments can be furnished for either controlling or signalling purposes.

"In the boiler and turbine room, resistance thermometers may be used for measuring and recording the temperatures of air ducts, bearings, steam temperature, condenser water, etc. They can be calibrated to read 'differential temperatures,' as, for example, the difference in temperature of the water entering and leaving the condenser. They are especially well adapted for measuring temperatures below 300 deg. fahr., which is too low for a pyrometer or where a mercurial, gas or liquid filled thermometer has not the required accuracy, or where it is not practical to run capillary tubing or reading a mercurial thermometer.

Control Instruments and Mechanisms

"To meet the demand for closer control of temperature, pressure, flow, etc., many new developments have been made on the control instruments and the mechanisms used to operate valves, rheostats, etc. Formerly automatic control was merely an 'ON' and 'OFF' proposition. If, for example, the temperature was low, the valve would be opened and the temperature would rise to a high value. The valve would then be closed and the temperature would drop to a low value. In this manner an average temperature was maintained, but considerable 'hunting' took place. With the new mechanisms conditions are anticipated automatically and corrections made before the 'hunting' starts. Also new mechanisms are available which vary the fuel supply in accordance with the fuel demand.

"In addition to the development of control instruments which would operate the above mechanisms, improvements have been made in the method of selecting and making control contacts. The galvanometer pointer merely selects the correct contact, according to the temperature, through a primary mechanism, and the operation of the contacts is taken care of through a secondary mechanism. The advantage of this scheme is to relieve the galvanometer pointer of strain, and at the same time the secondary mechanism has plenty of power to allow the use of wiping contacts. With this arrangement the duration of contact can be altered to meet the control conditions, as it is possible to time the duration by means of a simple adjustment.

"Control recorders can be supplied to control as many as six mechanisms from one instrument, the only limitation being that the point of control must be the same on all records.

The Brown Flow Meter

"The recently developed Brown flow meter uses well-proved principles, but combines them in a unique manner to make a simple, rugged and accurate meter.

"An orifice plate mounted in the flow line produces a differential pressure which varies with the flow, according to well established laws. This differential pressure is conducted to a manometer which is essentially a mercury filled

U-tube. The manometer is a simple pressure tight vessel of forged steel. The position of the mercury column is transmitted to the meter electrically by the inductance bridge principle. There are no electrical parts under pressure, and there are no stuffing boxes to leak or produce friction.

"A float on the surface of the mercury carries an iron armature which moves within a pressure tight non-magnetic tube. A divided inductance coil is mounted around this tube and a similar coil in the instrument. The meter coil is provided with a similar iron armature and electrical connections are made in a similar manner to the standard Wheatstone Bridge. Alternating current is used as a source of supply. As the armature in the manometer is moved up or down by the changes in mercury level, the reactance of the two halves of the manometer coil is altered. This unbalances the electrical circuit and causes the iron core in the instrument coil to move, which actuates a pointer. The result of this system is that any displacement of the iron core in the manometer coil is reproduced exactly in the other coil. This method of transmitting mechanical motion electrically is admirably adapted for transmission over long distances, and consequently the instruments can be mounted a considerable distance away from the manometer. The principal advantages of the inductance bridge principle in addition to the above are:

1. The electrical circuits are entirely independent of the pressure chamber. No stuffing boxes are necessary, as the effect of the iron core is produced on the coil through the non-magnetic tube which adequately seals the pressure chamber.
2. Electrical circuit is solid throughout, as all connections are either soldered or securely fastened under screws. No switches or other contacts are in the bridge circuit.
3. No errors are introduced due to voltage fluctuations, as the operation of the inductance bridge is independent of voltage in the same manner that a balanced Wheatstone Bridge is independent of voltage.

"The usual form of manometer is made of forged steel and is entirely suitable for a working pressure of 750 lb. per sq. in., although for special applications manometers can be supplied for higher working pressures.

"A very important feature of the design is the convenience of changing the range when necessary. It frequently occurs after installing a flow meter that the flow is greater or smaller than was estimated, or load conditions may change, thus demanding different range. To eliminate the necessity of changing the orifice plate, which usually means shutting down the line, a system of interchangeable range tubes has been devised. The range tubes can be readily changed and, by changing the chart to correspond to the new range tube, no readjustments are necessary except the setting of zero.

"A mercury blow-out check is provided to prevent the blowing-out of the mercury due to an excessive differential pressure. In case of a heavy overload on the line, resulting in an excessive differential pressure, the seal automatically closes, and after the overload is removed normal operation of the flow meter is automatically resumed.

"The high range manometer outlined above is offered in six different ranges. The lowest range gives full scale deflection on 1.60 in. of mercury and the highest range on 16.00 in. of mercury.

"In addition to this line of manometers, there is the intermediate line in several ranges from 2.17 in. of water to 13.71 in. of water and the low range line in ranges from 0.217 in. of water to 2.17 in. of water. These lines are for low pressure gas and air measurement and can be used in connection with the standard meters. The inductance bridge principle is used and, as in the high range line, there are no electrical parts under pressure and no stuffing boxes are used.

"The meters are of various forms suited to any requirements. The usual type is the 12-in. circular chart recorder, which may be furnished with or without an integrator which records the total quantity. An exclusive feature of the integrating recorder is the automatic planimeter which gives, on the edge of the chart, a continuous record of the quantity. By means of this, the quantity of flow for any period of time may be seen at a glance. This avoids the use of a planimeter and prevents inaccuracies in reading the counter. The counter, which reads in plain figures instead of by dials of the conventional type, is convenient for giving the total quantity per day.

"A 12-in. indicating meter with a bold dial and large pointer is offered for boiler room use, and a strip chart recorder is offered where that type of meter is preferred.

"The meters may be used in pairs; for example, an indicator may be installed in the boiler room and a recorder elsewhere. The electrical transmission system makes it possible to locate the instruments wherever convenient, without regard to the manometer location.

"All of the meters include the many important features characteristic of Brown pyrometers, thermometers, pressure gages, etc.

General Uses of Flow Meter

"While primarily designed for the measurements of gases, steam and liquids, the apparatus is readily adaptable for use as a liquid level indicator or recorder or both. The inductance bridge system can be used as a transmitting device to transmit light mechanical motions over long distances electrically.

Die Cast Aluminum Cases

"A recent improvement on all of the circular chart type and indicating type of flow meter, thermometers and pressure gages is the new die cast aluminum case, which results in a lighter non-corrosive case which readily takes a beautiful finish. Because the Brown Instrument Company has been ready to make large investments in dies and tools, it is possible to offer instruments of superior design, ruggedness and accuracy at no increase in cost."

STATEMENT BY THE KING-SEELEY CORPORATION, ANN ARBOR, MICH.

"The K-S Telegage is a distant reading gage for accurately registering in inches the depth of liquids in storage tanks. It is applicable to oil, water, gasoline, milk, chemicals and other liquids.

"The K-S Telegage is used on fuel oil storage tanks, in domestic, industrial and marine oil burners; also on locomotive tenders, hydroelectric plants, dry cleaning establishments, oil refineries, sprinkling systems and wherever it is desired to keep a check on the liquids stored in tanks. It is also used on the instrument boards of motor cars for recording the contents of gasoline tanks and is factory equipment on the majority of American and British cars.

"The K-S Telegage depends for its accuracy entirely upon the hydrostatic principle. It, therefore, has no moving mechanical parts that wear or require adjustment. The tank unit is a submerged air bell. The pressure of the liquid on the air in the bell varies in direct proportion to the head of liquid in the tank. This pressure is transmitted through the air line to the direct reading V-tube of the gage head.

"No matter where the storage tank is located, the Telegage can be placed at any reasonable distance up to approximately 500 ft. and at any point most convenient for reading, either above or below the tank. The reading is taken from a vertical liquid column. The dial is calibrated for inches of depth in the tank and has much the same appearance as an ordinary barometer.

"In addition to the usual gage line running from the tank unit to the back leg of the U-tube, two other lines are provided to prevent the possibility of blowing the reading liquid out of the top of the gage, or the syphoning of the tank contents under more than normal pressure. The second, or equalizer, line connects the top of the sight glass of the U-tube with the top of the tank, thus insuring that the pressure on the top of the recording fluid is always equal to that on the top of the supply tank. This is an important feature in insuring accuracy of reading and safety when long fill pipes extend at some height above

the tank, or when any abnormal pressure may come about in the tank. The third, or air supply, line runs from the gage to the tank unit, applying pressure from the pump directly at the tank. The three lines are furnished encased in flexible conduit fully protected and easy to handle, as shown in Fig. 34.

"Dials are supplied calibrated for the proper range of specific gravities of the liquids to be gaged. When liquids of varying weights are to be sorted in a tank, dials can be supplied graduated in absolute units of depth equivalent to inches of distilled water, and accompanied by charts that give the proper reading for any desired gravity."

STATEMENT BY THE HAYES CORPORATION, MICHIGAN CITY, IND.

"The Hayes Company continues with its standard line of instruments, which have been refined and improved. Recently we have added a type of draft gage new in principle and design, the instrument being free of floats, tanks, magnets or liquids.

"The gages are made in two types, Type F for one or two units, and Type V for any number of units up to twelve or more.

"In either F or V type the pointer can be made to move over the entire scale by a fraction of an inch water (a few millimeters), or the total scale range may be 6 or 8 in. water for blast pressure or 30-in. water pressure for powdered coal air lines.

"With a different mechanism higher pressures can be indicated just as accurately and as clearly.

"The operating mechanism shown in Fig. 35 and 36 consists essentially of a slack leather diaphragm and a phosphor bronze cantilever spring attached to a pointer, which is mounted on a pivot bearing. The diaphragm is a pliable, tough, gas-tight animal membrane which the Bureau of Standards found to be ideal for this kind of service. The diaphragm merely transmits the force of the draft or the pressure to the flat bronze spring, which in turn moves the counterweight pointer and produces a reading on the scale in direct proportion to the magnitude of the force.

"The spring is harnessed directly to the pointer in the simplest possible manner, using a strong non-kinkable, nickel-silver bead chain. The large area of the leather diaphragm produces such great magnification in the pressure that a surprisingly powerful force is dealt with. The spring is held rigidly at one end, and its movement is well within the elastic limit, so these gages hold their calibration indefinitely.

"The position of the strong spring determines the position of the pointer, and the spring is moved in proportion to the magnified force which is applied through the slack

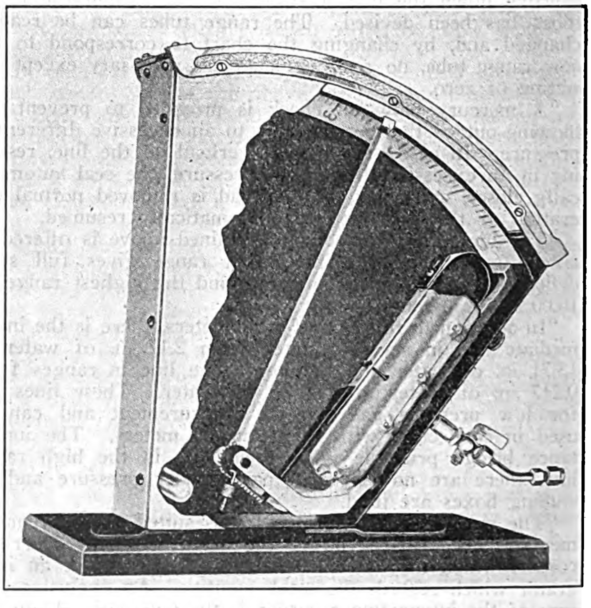

FIG. 35—OPERATING MECHANISM IN THE HAYES POINTER DRAFT GAGES, HAYES CORP.

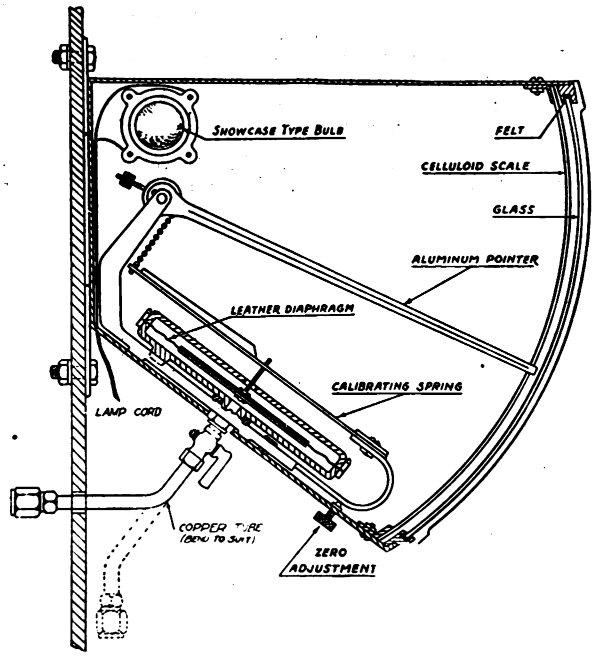

FIG. 36—OPERATING MECHANISM IN THE HAYES POINTER DRAFT GAGES, HAYES CORP.

leather diaphragm. The movement is the smoothest imaginable, and no dashpots or dampeners are necessary, as the pointers do not bob up and down. The pointers move promptly and definitely without the least sluggishness and can be depended upon to be accurate at all times. There is no surging and no changing liquid level. Vibration of walls and buildings and rolling of ships do not spoil the readings, as would be the case with swaying floats and liquids.

"The diaphragm used in the Hayes draft gages is an animal membrane, treated by a patented process.

"The leather is of a similar grade to that used to hold the rare and expensive helium gas in 'lighter-than-air' machines. Its strength and impervious nature, as well as ability to change shape according to the altitude and the amount of gas contained, make it ideal for this strenuous service."

POWER PLANT ENGINEERING. Furnace Operation Shown by Draft Measurement. Pp. 15-18, Jan. 1, 1928.

Fuel bed conditions, excess air leakage, variations in load, fallen baffles, give characteristic readings on draft gages. Various types of draft gages illustrated.

POWER PLANT ENGINEERING. Gas Measurements Indicate Efficiency. Pp. 19-23, Jan. 1, 1982.

Significance of temperatures and analyses of gas show operation of boilers and means available for securing these conditions.

POWER PLANT ENGINEERING. Means of Controlling Boiler Pressures. Pp. 35-39, Jan. 1, 1928.

Indicating and recording steam pressure gages, methods of testing and calibrating them, safety valves, capacity and tests.

POWER PLANT ENGINEERING. Temperature of Steam Is an Important Factor. Pp. 41-45, Jan. 1, 1928.

Temperature is measured with various types of thermometers, gas-filled vapor tension thermometers, thermocouples and resistance pyrometers, moisture in the steam determined for various types of calorimeters, which are illustrated.

POWER PLANT ENGINEERING. Measuring and Recording the Flow of Steam. Pp. 46-50, Jan. 1, 1928.

Description of the principles and mechanism of a number of flow meters, which consist of a primary element acted upon by screws, and a secondary element which transforms the action into an indication or record of the amount of flow.

POWER PLANT ENGINEERING. Measurements on Steam Engines and Turbines. Pp. 52-54, Jan. 1, 1928.

Determination of lb. of steam per kw-hr. for indicated h.p., use of indicator, methods of weighing condensed steam, use of dynamometers, etc.

POWER PLANT ENGINEERING. Condensed Operation. Pp. 57-60, Jan. 1, 1928.

The engineer must keep records, make frequent tests and maintain equipment in first class condition to secure best results.

POWER PLANT ENGINEERING. Air and Steam Measurements Most Difficult. Pp. 59-63, Jan. 1, 1928.

Instruments to be used in the measurements of air and steam conditions in the condenser. They must be carefully located and used to give reliable results.

POWER PLANT ENGINEERING. Speed Measurements Should Be Accurate. Pp. 194-195, Feb. 1, 1928.

Description of many types of speed indicators and recorders which simplify the speed measurement problem.

POWER PLANT ENGINEERING. Many Meters Develop Measure of Flow. Pp. 338-340, March 15, 1928.

Illustrated description of different types of meters. In general meters of same type have been developed to measure air, steam, gas or water, although details of meter construction for different fluids may vary considerably.

DISTILLATION PRODUCTS OF COAL

LOW TEMPERATURE CARBONIZATION

Present Status and Future of the Industry

During the past year the manufacturers primarily interested in the development of low temperature carbonization processes have done a great deal of work toward putting present experimental installations into commercial operation. New processes have been developed and installed. At the same time chemists have worked in associated fields in an endeavor to find the best methods of using the byproducts (in particular the tars) derived from such processes.

From the purely commercial standpoint, for conditions in this country it appears that no process has as yet proved itself in practice, particularly for use in connection with steam power plants. It is, of course, such a development that most interests the engineer entrusted with the design of power plants in his search for the process making the highest economic use of fuel.

Even the best known processes are still in an experimental stage of development, although in some of them it has been possible to correct most of the troubles that have been encountered during trial operation. Encouragement is found in the continuous successful operation of the KSG process at the Stinnes plant near Essen, Germany, since December, 1926, and the Coalite plant at Barnsley, Yorkshire, England. It is stated that the former has operated on a commercial scale since 1924, with a throughput of approximately 80 tons daily, and that the latter has been operated commercially since July, 1927, treating 200 to 250 tons of coal per day.

Power plant engineers in this country center their interest on the McEwen-Runge[1] plant installed at Milwaukee, but little information is available at the present time on the actual operation, except that from time to time difficulties have been encountered and eliminated. This plant, as well as the KSG plant recently installed at New Brunswick, N. J., is owned and operated by the holder of the patents covering the processes. The Milwaukee plant may be considered as an installation suitable for operation on a large scale; in the New Brunswick design provision has been made for commercial experimentation as well as for large scale operation. Because of the conditions underlying these installations, information concerning performance is not as easily obtainable as it would be if the ownership were in the hands of concerns primarily interested in the commercial results of the individual plants; these remarks are not intended as criticism of the owner's attitude, but to explain the circumstances that confront the power plant engineer in his study of these developments.

It should be noted that the reported commercial success of the KSG process in Germany is based on economic conditions quite different from those prevailing in this country, construction and operating costs being materially higher here; in addition, the price obtained for tar in Germany is considerably above that at present obtainable in the United States. It is, therefore, quite clear that even if this system can be economically justified for use in this country, the margin of profit will be considerably smaller than in Germany; consequently the data used in any estimate of results must be as accurate as possible.

Factors to Be Considered

While it is, of course, possible to reduce to a common monetary standard the cost of coal in Germany and the United States, such a comparison is only part of the story, and before the correct economic status of any process can be estimated, factors such as labor, materials, natural resources, markets and cost of money must be given consideration. When capital and labor costs are relatively low, it is in general easier to justify a carbonizing process than when they are high. In the United States there are large coal deposits, natural gas resources and petroleum fields, and these facts must be taken into consideration when comparison is made of justifiable capital expenditure in the United States and in Germany, England and other countries.

The essential problem for the power plant designer is, of course, an economic one rather than purely thermal. The importance of the byproducts obtained from the low temperature processes has often been pointed out. Sufficient monetary return must, however, be realized over a period of years to pay for the additional coal used, to offset the thermal losses, to cover the extra investment and operating cost, and in addition to afford a reasonable margin of profit, in order to make the installation attractive.

No general conclusions may be drawn about the economic success of any specific type of low temperature process, as everything depends on the locality where the installation is to be made and the possibility of marketing the byproducts. The coke, containing 70 to 80 per cent of the total heat of the products, will be the main source of income, but the ready marketability of the gas and tar produced will be an important factor in determining the success of the installation.

In general, it may be said that these processes should be more successful in densely populated sections of the country, where a large demand for smokeless domestic fuel as well as for gas exists. If a part or all of the coke is to be used for steam-electric generation, the power and gas producing companies should be closely affiliated or working under the same management, as close and harmonious cooperation would result in large savings.

---

[1] See paper by Roland P. Soule before the Fuels Division of the A.S.M.E., Feb., 1928.

Publication No. 289-69, Serial Report, Prime Movers Committee.

In particular, so far as the electric power and light industry is concerned, a process that involves the least expense for investment and operation would be the most adaptable. As gas is generally the best and most expensive type of fuel, every effort would be made to sell it for domestic use, where the highest price could be secured. The coke not salable for domestic use would be used for steam production and could be burned with good efficiency, in whatever form produced, in one or more of the ordinary types of furnace. Attempts have been made to burn low temperature coke in pulverized form with a horizontal burner, but reports received indicate that the fire could be maintained only by using considerable bituminous coal with the coke. It is the opinion of engineers familiar with pulverized fuel equipment that low temperature coke should be burned in a vertical type of burner, in which the flame is directed downward.

A process like the KSG produces a high-grade domestic fuel that would be too valuable to be burned under steam boilers; this process is better adapted for use in connection with existing gas works, where the high heat value gas produced would be mixed with the low value gas produced in regular gas retorts. These facts make it plain, as stated by the promoters, that the KSG process is not a system especially adaptable for use with power plants. The process is described in Dr. Runge's paper, presented at the Fuel Division Meeting of the A. S. M. E., December, 1927.

The gas resulting from the usual low temperature carbonization process, having a higher B.t.u. value than the requirement of the commissions, would in general have a ready market. The gas from the KSG and McEwen-Runge processes falls in the high B.t.u. category. There are, however, processes in which the B.t.u. of the gas is lower than the commissions' standards, and in such cases the value of the gas would be about the coal equivalent.

Possibilities of Low-Temperature Tar

The byproduct from low temperature carbonization that has received the greatest attention is the tar, as the financial return from it will in many cases decide the economic success of an undertaking. Many possibilities have been pointed out. The characteristics of this low temperature tar are very different from those of the high temperature product, and the superior value of the new product for purposes other than as fuel oil has sometimes been questioned. When used as liquid fuel without refining, it would have approximately the value of petroleum. It is improbable that there will be a wide use of low temperature tar for road surfacing as it lacks the necessary binding qualities.

A simple refining process applied to low temperature tar yields 70 per cent of creosote and a residue of 28 per cent of pitch, figuring the losses as 2 per cent. The creosote obtained does not fully comply with the rigid specifications for wood preservative in this country, but its value for this purpose has been shown by numerous tests since 1921.

The consumption of creosote for wood preserving in this country has increased during the last decade or so between 10 to 15 per cent every year, and the total consumption in the United States in 1927 was over three-quarters of a million tons. Over 40 per cent (41.4 per cent during 1927) of the total has been imported from England and Germany, with prices as high as 18½ cents per gallon. It is reported that a zinc meta arsenite process for treating poles, developed by the research department of The Western Union Telegraph Company, is cheaper and more effective than creosoting. This may possibly affect the value of creosote.

It has been estimated that, with 15 cents per gallon for creosote and $4.50 per ton for pitch, the net return on the tar after deducting all refining charges would be over 8 cents per gallon. The producer of low temperature tar, particularly if it should be a gas or electric power company, would hardly intend to complicate the operating process by distilling tar. However, the development of new uses, and in particular the one mentioned above, would create a better market for the product and improve its price.

Interest in Manufacture of Resins

Since the Bakelite patents have expired, wide interest has been shown in the manufacture of resins. Although the price for this product has been considerably lowered (from a former price of $1.00 to 25 cents per lb. at the present time), it has been variously estimated that it might still be profitable to produce resins from low temperature tar. New uses have been found for this product, and chemists working in this field think that this industry is only in its infancy. But it is admitted that prices for low temperature resins would have to be kept below that of Bakelite in order to attract attention in the market.

The manufacture of resins yields by weight 11 per cent for this product with 57 per cent return in creosote and 28 per cent in pitch. After deducting all manufacturing and refining charges, it is estimated that a net return of over 10 cents per gallon of tar would result. This figure is based on prices for creosote and pitch as shown above, and 18 cents per lb. for resin. No special value is attached to the pitch resulting from the refining process, except that it could be used for fuel.

Foreign Developments

Interesting conditions are developing in Germany, where great efforts are being made to improve the economic situation of the nation as a whole by reducing imports and increasing exports. The financial powers controlling the supply of domestic fuel do not look very favorably upon the threatened augmented supply of domestic coke that would result from the expansion of the low temperature carbonization industry. It is felt that this new developmen should find other fields for its products or produce them in such form that they may compete with fuels now imported, such as fuel oil and gasoline; or that its products (e.g., synthetic ammonia) should be exported or be used in fertilizer manufacture or in the chemical industry.

Stimulated by these considerations, great progress has been made during recent years in methods of extracting hydrogen from the gases produced from high and low temperature carbonization processes. The hydrogen is used for the manufacture of synthetic ammonia, as well as for the manufacture of liquid motor fuel by the Bergius process. The hydrogen in the coke oven gas represents about one-half of its volume and one-third of its heat value. The residual gas, therefore, has a higher heat value per unit of volume than the original coke oven gas. Considering the tremendous amount of gas liberated during coal distillation, a wide field is open for these new methods where economic conditions are favorable. Processes have been developed in Germany by Linde, in France by Claude, and in Italy by Casale.

In the Ruhr Valley in Germany a new plant is being erected for a daily capacity of about 100 tons of coal, which will try out the Bergius process on a large scale using every kind of fuel available. This new plant is considered in Germany, not as a commercial proposition, but rather as an experiment.

Considerable research work has been done in England, Canada and in this country, which will be of great value to engineers who study the application of low temperature distillation to a specific installation. Assay tests have been made using the various fuels available for distillation. Detailed information may be found in the various reports published by the British Fuel Research Station, in an article by Davis and Galloway in *Industrial and Engineering Chemistry,* June, 1928, reporting on tests made by the U. S. Bureau of Mines, and in the report on tests made by the Canadian Department of Mines in *Gas Age-Record,* March 17, 1928. Although it is realized that the yield from the various coals, when carbonized in large retorts, will be different from that shown in the tests, these tests are valuable as an indication of comparative amounts of the by-products available from the various fuels.

Low Temperature Carbonization

It is worth while to learn of the attitude of some engineers prominent in the field of power generation, with respect to the relation of their industry to low temperature carbonization. One of these men, who has studied this problem both here and abroad, has concluded that the processing of coal is something to watch and keep in touch with; for the moment, however, he does not see any process that electricity supply companies should spend money on. The American Gas Association Report of 1928 covering this subject quotes the opinion of a well-known authority on fuels in this country; after discussing the results of a process that has been successful in Germany, this engineer writes as follows:

> "However, it is very doubtful in my mind whether success in one or two localities peculiarly favorable for such operation should be taken to imply any large opportunity in the United States for low temperature processing of coal in the immediate future. But even though it may seem quite pessimistic, I think we should frankly face the fact that the appropriate economic niche in our fuel and energy system has not yet been found for low temperature carbonization. When discovered for one locality, it is not necessarily known for another. And the enlargement of the niche to afford enlarged possibilities for low temperature processing will be a slow and financially painful procedure at best."

George Orrok, during the discussion of his paper on the economics of coal carbonization in the United States, presented at the Fuels Division Meeting of the A. S. M. E. in May, 1927, was accused of pessimism. However, his attitude and conclusions seem entirely justified and logical in the light of the data upon which they were predicated—at least until more definite information becomes available on the commercial aspects of the problem.

CONTRIBUTED STATEMENTS

DR. FR. MUELLER, KOHLEN SCHEIDUNGS GESELLSCHAFT, GERMANY

Dr. Mueller, who has been interested and active in the development of the KSG process in Germany, thinks that the outlook for low temperature distillation of coal is very promising in Germany and in the whole of Europe, and that undoubtedly there will be a field of operation for the various processes developed. He states that the low temperature coke produced must be a marketable product, as the largest part of the returns flows from it. Dr. Mueller sees a great future in the extraction of hydrogen from distillation gases, to be used for the manufacture of synthetic ammonia and the liquefaction of coal.

DR. C. H. LANDER, DIRECTOR OF THE FUEL RESEARCH BOARD, DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH OF THE ENGLISH GOVERNMENT

The following paragraph is a summary of statements made by Dr. Lander when interviewed by one of the leading power plant engineers in this country:

It is believed that no carbonization process available today can be economically used by electricity supply companies, unless it be some particular company like the Milwaukee Electric Railway & Light Company, where the gas and the electricity companies work in harmony and where other activities will absorb the bulk of the by-products. To make any of the processes worth while, the carbonization plant should be jointly owned and operated with the gas company, which through training and experience is in a better position to operate a process plant.

THE BABCOCK & WILCOX COMPANY

Distillation of Power Plant Coal

In the problem of reducing generating costs, every item of expense has separately been the subject of continuous effort, and among all these the fuel expense per kilowatt-hour has been reduced the most. However, the fact that fuel expense is still a large item of total cost has directed attention to the possibility of further reducing it by coal processing, such as distillation or carbonization.

Many interesting schemes for coal treatment have been proposed, and the ingenuity of some of them has tended to divert interest from the main issue, that is their value. Some of these schemes have proved to be unworkable or nonoperative, and others that were workable have failed to reach the stage of commercial success. These failures have not stopped the flow of new proposals, though they have had the effect of diverting the attention to valuation rather than technology. For the future it is to be expected that each new scheme for the distillation of power plant coal will be subjected first to the valuation test, assuming it to be workable; then, if the answer is favorable, an effort to make the scheme work would be justified.

A coal treating process may be economically judged by itself as a manufacturing operation, by comparing sales value of products with cost of producing them. On the other hand, it may be judged as an accessory to a steam power plant, by comparing the cost of steam with and without the coal process working in relation with the boilers.

It seems best that the first study be made from the second viewpoint, for many reasons, among them being the fact that there is in the steam power plant, a known market for any coal treating process that can be proved to be capable of reducing the cost of steam without impairing normal plant operation.

The first actual step must be the adoption of a suitable unit of cost, and this is "cents per million B.t.u.," rather than cost per ton of coal, per kilowatt-hour or per pound of steam. The B.t.u. is a prime factor in the rest, and the whole operation of the plant is energy conversion from one form to another, each with energy losses and money expenses. In what follows a million B.t.u. will be called a Unit.

The next step is the adoption of the principle that every energy transformation imposes three increments of cost over the original cost—"A." These are:

The inefficiency increment due to losses of energy—xA.

The investment increment representing all fixed charges —I.

The operating increment representing all disbursements due to operation—O.

The inefficiency increment of cost is the increase in cost per million B.t.u. due to losses quite independent of all other expenses. If E is the thermal efficiency or ratio of output to input energy for an energy transformation, then

$$\text{Inefficiency Increment} = \left(\frac{1-E}{E}\right) \times \text{original cost per Unit.}$$

If the cost per Unit after a transformation is B cents per Unit, and A the cost before, then

$$B = A + xA + I + O$$
$$= A + \left(\frac{1-E}{E}\right) A + I + O$$
$$= \frac{A}{E} + I + O$$

These principles were first expounded in a paper presented by Prof. Charles E. Lucke before the A. S. M. E. Metropolitan Section in April, 1924, and shortly afterward to the Schenectady and Boston Sections. It is entitled "Value of Efficiency in Transforming and Distributing Energy," and contains many numerical values, starting with the cost of fuel in cents per Unit.

Applying these principles to a steam power plant for which the costs are known, without coal processing, it is possible to determine how much the processing itself may cost without increasing the power generating costs, if two sets of data are available. The first is the yield of gas, tar and coke, with quality of each, and the second is the market price or credit value in cents per Unit for energy in each of the three forms and of the quality available. It is possible to make reasonably safe estimates for the products' values, but the figures for yields and qualities of products must be determined experimentally as characteristic of the process, of the coal and of the operating conditions—especially temperature—when the process is one of carbonization. With either actual results or reasonable assumptions for the numerical values of these two sets of data, the allowable total costs of the processing per Unit, to keep power costs the same, can be determined, or it is possible to fix an equalizing purchase price for the coal processing equipment if its efficiency and operating expenses are determined. This equalizing purchase price is what the power plant could afford to pay for a coal processing installation, with no change in its power cost, and it is, therefore, a maximum possible sales price. Any actual coal processing equipment would be valuable to the power plant in proportion as it costs less than this figure.

Working in the opposite direction, the determination of the price at which products of the coal could be sold, with no change in the cost of power, becomes possible as soon as the coal processing costs are known, and any prices obtainable above these figures represent profit applicable to reduction of power costs or to dividends.

To illustrate the procedure, an example will be worked out for application of a coal process to a power plant; the figures used are to be regarded as purely illustrative and not as representing any particular power plant or coal process. It will be assumed that the yields and qualities of the coal products are known, but that the cost of the equipment and its operation are unknown. It will also be assumed that present power costs are known, and that the problem is to determine the maximum sales price for the coal processing equipment based on an assumed efficiency and operating expense, or its highest permissible total operating expense after installation, for keeping power costs equal to what they were before.

The data for the assumed steam power plant will be taken from the above mentioned A. S. M. E. paper, as given for a plant of 25,000-kw. capacity, these data being reasonably correct for sizes up to about 75,000 kw. Other assumptions are—a coal of 12,722 B.t.u. per lb., at about $4.00 per ton of 2000 lb., costing 16 cents per million B.t.u. and having about the following analysis: Fixed carbon, 50.95; Volatile, 35.00; Moisture, 3.15; Ash, 10.90; Total, 100 per cent.

POWER COST FOR STEAM TURBINE POWER PLANT

Capacity	25,000-75,000 kw.	
Annual average load	40% of capacity	
Fixed charge rate on investment	12% per year	
Coal, 12,722 B.t.u./lb	16c. per Unit	
Efficiencies, yearly average:		
Coal to superheated steam	71%	
Superheated steam to b.h.p.-hr	20.03%	
Brake h.p.-hr. to kw-hr	92%	
Overall, coal to kw-hr	13.1%	
B.t.u. in coal per kw-hr., yearly average.		26,100
Investment:		
Real estate, etc	$2.00 per kw.	
Building, stack, etc	12.00	
Boiler room equipment	25.60	
Piping, etc.	11.30	
Turbo-generators	39.50	
Electrical switching, etc.	4.20	
Miscellaneous	4.40	
Total	$99.00	$99 per kw.
Power Costs:		
Fixed charges	0.34c. per kw-hr.	
Operating labor and material	0.40	
Fuel	0.42	
Total	1.16c. per kw-hr.	1.16c. per kw-hr.

For present purposes it is necessary to analyze the figures in greater detail for that part of the plant operation concerned with steam making from coal. This requires an apportionment of real estate, building and miscellaneous investment charges as well as labor and material for operation. The result, which follows, includes piping to give costs up to the turbine, which may be going too far.

STEAM COSTS, CENTS PER KW-HR. FOR POWER PLANT
(25,000 — 75,000 kw.)

Investment:	Per kw.	
Real estate for boiler room......	$ 1.00	
Building for boiler room........	6.00	
Equipment for boiler room......	25.60	
Piping to turbine...............	11.30	
Miscellaneous	2.29	
Total	$46.19	$46.19 per kw.
Fixed charges		0.158c./kw-hr.
Operating labor and material....		0.18
Fuel		0.42
Total steam costs.............		0.758c./kw-hr.

It is next necessary to convert these costs in cents per kilowatt-hour, their most common unit, to that adopted for present purposes, cents per million B.t.u., or cents per unit.

STEAM COSTS, CENTS PER UNIT (1,000,000 B.T.U) IN STEAM

Efficiency, coal to superheated steam, yearly average...71%
Cost of coal......................... A = 16.00c. per unit
Inefficiency increment $\left(\frac{1-E}{E}\right) \times A =$ 6.53
Investment increment .... I = 8.50
Operating increment .... O = 9.70
Total, cost per million B.t.u. in steam .... B = 40.73c. per unit

It is interesting to note that with energy in coal costing 16 cents per Unit, it has risen to 40.73 cents per Unit in the form of heat of superheated steam; so it may be stated that for steam making from fuel—

$$\text{Commercial efficiency} = \frac{16.00}{40.73} = 39.4\%$$

With such a set of figures for an existing power plant, it becomes possible to approach the problem of finding the effect of adding to it some coal process equipment, such, for example, as will produce gas and tar for sale and leave coke to be burned to make the steam. To do this requires data on yields and efficiencies somewhat like the following, the numerical values being merely illustrative but not unreasonable:

COAL PROCESSING DATA

Yields per ton coal (2000 lb.)	
Gas	3,400 cu. ft.
Tar	20 gal.
Coke	1,600 lb.
Quality-calorific power	
Gas	900 B.t.u./cu. ft.
Tar	100,000 B.t.u./gal.
Coke	12,700 B.t.u./lb.

HEAT BALANCE

Input—In calorific power of coal 12,722x2,000.	= 25,444,000 B.t.u./ton coal
(Heat 983,000).....	
In process heat (steam 1,300,000).....	2,283,000
Total........................	27,727,000 B.t.u./ton coal
Output—In calorific power of gas 900x3,400..	= 3,060,000 B.t.u.
Tar 100,000x20..................	= 2,000,000
Coke 12,700x1,600...............	= 20,320,000
Total........................	25,380,000 B.t.u.

$$\text{Thermal efficiency of coal process} = \frac{25{,}380}{27{,}727} = 92\%$$

If steam costs are to remain the same, and coke be valued at the same price as coal, i.e., 16 cents per Unit, the coal process costs can be set up.

Per million B.t.u. in coke required for steam making, there will be produced

98,000 B.t.u. in tar
150,000 B.t.u. in gas

These have credit or sales values estimated as follows. For the gas, the last report of the American Gas Association's Carbonization Committee for 1927 gives figures that may be regarded as a maximum for gas, based on its use as a blue water gas enricher in place of gas oil. This procedure fixes the value of high calorific gas such as 900 B.t.u. per cu. ft. by the cost of gas oil, and one report says that such gas would be worth 40 cents per 1000 cu. ft. for carburetting purposes. This is 40 cents per 900,000 B.t.u. or 44 cents per Unit. Other reports state that its value to a water gas works as an enricher would be between 40 cents and 60 cents per Unit, or 4 cents to 6 cents per 100,000 B.t.u., or per gal. of gas oil—its use equivalent. Gas of lower calorific power is worth less, and a scale of values could be worked out from a mean of 50 cents per Unit for 900 B.t.u. gas down to some lower figure corresponding to present costs of manufacture of blue water gas of approximately 300 B.t.u. For present purposes of illustration the value of the gas is taken at 50 cents per Unit as a water gas enriching agent.

For the tar, the minimum value will be that of a boiler fuel and so identical with the coal, which in the present example is 16 cents per Unit. At present it has a higher market value, and the maximum may be taken at some ratio to that of gas oil or fuel oil. For present purposes of illustration this will be set at one-half the value of gas oil, which would bring it to 2 or 3 cents per gallon of 100,000 B.t.u., or 20 to 30 cents per Unit, and the mean of 25 cents per Unit is used in what follows.

Expenses for the coal process begin with the coal at 16 cents per Unit, and to this must be added the cost of the heat used by the process. Such heat as is used to raise and hold the temperature required by the process and which may be derived from burning fresh coal, is to be charged at the coal rate of 16 cents per Unit, or at a lower value if boiler waste heat is used, or a higher value if, for example, steam or electricity is used. One-half of the cost of coal heat is charged in the present example. Heat of live steam, whether used as an atmosphere or a means of establishing a process temperature, is chargeable at the live steam cost of 41 cents per Unit, but if waste or partially expanded steam is used, a lower price will be proper.

The heat supply costs will then be as follows:

Heat Source	Units/Ton Coal	¢ Per Unit	Total ¢
Cal. power of coal....	27.7	16	440
Process heat	1.0	8	8
Steam	1.3	41	53
Total.............	30.0		501

$$\text{Net cost per Unit input heat} = \frac{501}{30} = 16.7¢ \text{ per Unit}$$

Considering coke as a boiler fuel to be the prime product of the coal processing, then the efficiency of the process is

$$\frac{20{,}320{,}000}{27{,}727{,}000} = 73 \text{ per cent.}$$

With this figure, the first of the three increments of cost for the coal process becomes:

$$\text{Inefficiency increment} = \frac{1-E}{E} \times A = \frac{27}{73} \times 16.7 = 6.3¢$$

The other two increments, investment and operating, are unknown, but their total can be evaluated for equal steam costs as follows:

COAL PROCESSING COSTS PER UNIT (1,000,000 B.T.U.) IN COKE

Expenses:
Efficiency, coal to coke...... 73%
Cost of input heat (coal).... (heat).... (steam).... A = 16.7¢ per Unit
Inefficiency increment, $\left(\frac{1-E}{E}\right) \times A$ = 6.3
Investment increment........ I = I
Operating increment......... O = O
Total, B = ... 23.0 + I + O cents.

Credits:
From gas 0.150 Units per Unit in coke × 50¢ = 7.5¢
From tar 0.098 Units per Unit in coke × 25¢ = 2.5¢

Total, B′ = 10.0¢

Net cost per million B.t.u. in coke, $B - B' = 13.0 + I + O$¢

This coke as a boiler fuel is valued at 16 cents per Unit, the purchase price of coal, and taking this as the cost, it follows that:

$$16.0 = 13.0 + I + O$$

and $I + O = 16.0 - 13.0 = 3$¢/million B.t.u. in coke

If, therefore, the coal process can be operated at less than 3 cents per million B.t.u. in coke delivered as a boiler fuel, all fixed charges and disbursements included, the process will be profitable; otherwise it will not when it is operated as an auxiliary to a steam power plant—subject to the accuracy of all the numerical values used.

Referring back to the boiler plant before installation of the coal process, it is to be noted that the sum of these two increments of investment and operation is:

STEAM BOILER PLANT

		Per Unit In Steam		Per Unit In Fuel
Investment increment	=	8.5¢	=	6.0¢
Operating increment	=	9.7¢	=	6.9¢
Total	=	18.2¢	=	12.9¢

It would, therefore, follow that a coal process will pay when the sum of its investment and operating increments of cost is equal to or less than $\frac{3.0}{12.9} = 22$ per cent of that for the boiler plant in cents per Unit or *dollars per year*, when the numerical values are as assumed. If the ratio of operating expense, exclusive of fuel and heat, to fixed charges were the same for the coal process as for the boiler room without it so that its installation did not change the ratio, then the investment in coal processing equipment can be estimated. In this case the investment allowable would be 22 per cent of that of the whole boiler plant, $46.19 per kw., which is $10 per kw. This means that a coal processing equipment would pay, if it cost less than $10 per kw. installed with all charges, and any less cost would be a measure of profit—all on the assumption of accuracy of the figures used.

For an actual case, other figures would apply, and for them there would be another answer; exactly the same method would, however, be applicable. This method is submitted for consideration as a tentative standard to be used in future work on coal processing evaluation for steam power plants, and for approval and adoption if, after study, it is found acceptable with such modifications as may be found desirable.

FOREIGN DEVELOPMENTS

England

The British Government is very anxious to create the facilities for an independent supply of motor fuels for the British Isles, and therefore does everything possible to stimulate the erection of low temperature carbonization plants. The government has levied an import duty of 4d per gal on fuel oil and petrol. This duty applies also to motor spirit manufactured in England from imported oil. This should stimulate the manufacture of these products from domestic coals and coal distillates. A great number of companies have been formed in order to exploit processes, but few of these processes have as yet been developed.

Of importance is the cooperative project of the British Government with the Gas, Light & Coke Company at London. The "Fuel Research Station" process will be used, and the plant will have a capacity of 100 tons per day. The British Government has guaranteed $500,000 for the erection of the plant, and the Gas, Light & Coke Company has guaranteed to operate the plant for three years as continuously as possible. The plant is not expected to start operation until late in the summer of 1928.

The Coal Oil Extraction, Ltd., of London is completing negotiations for the erection of a 500-ton plant.

A "Fusion Process" plant of 20 tons capacity has been in operation for several months at the Welbeck Collieries, Nottinghamshire.

Experiments have been made on a small scale with the "Hird Process."

In the Laing and Nielsen Process, operated by the "L & N" Coal Distillation, Ltd., of London, internal heating is applied in slightly inclined, fire-brick lined, rotating cylinders.

The Parker Process is used by L. T. Carbonization, Ltd., London; a 50-ton capacity plant was tested by the Fuel Research Board in 1924. A plant of improved type has been operating since July, 1927. at Barugh. This installation consists of 5 batteries each having 32 retorts, each retort containing 12 vertical cast iron tubes; 1500 tons of coal carbonized per week yield over 1000 tons of Coalite at 14,492 B.t.u. per lb., 28,200 gal. of oil, 3750 gal. of benzol and 7,000,000 cu. ft. of gas carrying 700 B.t.u. per cu. ft. The process consumes 2,500,000 B.t.u. per ton of coal carbonized.

The "McLaurin Process," operated by the Dalmarnock Gas Works, Glasgow, uses internally heated vertical retorts, carbonizing 50 to 70 tons per day.

The Midland Coal Products Process is in operation at an experimental plant at Netherfield, Nottingham. A plant of 500 tons capacity per day is in process of erection at the Askern Collieries, and another of 300 to 400 tons capacity, is to be erected at the Shipley Colliery.

Germany

The Plassmann Process has been developed by the Chemisch-Technische Gesellschaft at Duisburg, and a plant of 400 tons daily capacity is being installed at the Prosper mines at Essen. External heating is used in this process.

France

A plant of 200 tons daily capacity of the KSG type is being installed in the "Mines de Marles," near Paris.

Two units of the Salermo Process, with a capacity of 25 tons per day, have been working for over a year at the Sarre mines.

Spain

During July, 1927, a contract was signed by the "Cooperativa de Fluido Electrica," of the City of Barcelona, Spain, for the erection of a 500-ton plant of the KSG type.

WORLD POWER CONFERENCE, LONDON, 1928

Low Temperature Carbonization Plant at Newcastle-on-Tyne

R. P. Sloan reports on the results and future prospects of this 100-ton experimental installation. His conclusion is that under present conditions it is not likely that any large direct economies will result from low temperature carbonization, but that conditions may change; consequently, the careful study and extensive experiments that are being made in this direction may be of the greatest use in the future. At this coal distillation plant, which is at the Dunston power station of the Newcastle-on-Tyne Electric Supply Co., no important commercial economies have so far been obtained. Detail figures in the report show the returns obtained from the sale of by-products, the semi-coke and gas being burned under the boilers and therefore credited with their straight fuel value. The thermal balance shows 76 per cent of the original heat in the coke and gas, 12 per cent in the oils and 12 per cent consumed in process.

Frequent experiments and alterations have been necessary in order to adapt the system to the power plant and to make it operative.

The plant consists of four retorts and four boilers. One boiler is arranged for pulverized fuel firing to carry the peak loads. Two coke fired boilers are built together, having a combined evaporative capacity of 18,000 lb. of steam per hour, and are working in conjunction with two retorts of 20 tons capacity each. One coke fired boiler with 30,000 lb. evaporative capacity works with two retorts with a combined capacity of 60 tons per day. The complete distillation plant, therefore, is able to handle 100 tons of coal per day.

The paper gives a complete description of plant and performance. The raw coal is preheated before entering the retort by the waste flue gases, and the hot coke is discharged directly to the stoker hoppers in order to save the sensible heat.

The total cost of operation and maintenance, based on actual operation for the last three years, is given as 4s. 8d. ($1.13) per ton of coal distilled.

INTERNATIONAL CONFERENCE ON BITUMINOUS COAL, PITTSBURGH, 1928

Low Temperature Carbonization Processes

Low Temperature Carbonization of Coal by the Carbocite Process (W. H. Allen).

After giving a summary of the preliminary work since 1925 with a small experimental retort, the author describes the semi-commercial test unit in operation at Philo, Ohio, since July, 1927.

The process essentially consists of the continuous treatment of coal in horizontal or slightly inclined rotary furnaces. Crushed coal is dried and preheated to 450 deg. fahr. in the first rotary drum called the "Thermodizer." In the secondary or "Carbonizer" drum the temperature is raised to 900 or 950 deg. fahr. as the distillation and coking take place. It is found that with West Virginia coal, when the process is extended sufficiently to reduce the volatile matter to about 12 or 14 per cent, the resultant coke is tough and still dense. The pieces vary from ¼ in. diameter to 4 in., and even larger. The resultant gas, after removal of liquids, has a heat value of about 800 B.t.u. per cu. ft.

The drums consist of an inner and an outer shell, leaving a 2-in. space for the heating gases. Since August, 1927, there has been distilled nearly 4000 tons of coals, mainly from West Virginia and Ohio, with a maximum of 43 tons per day. The test plant has been shut down in order to increase the length of the Carbonizer drum from 30 to 60 ft.

The chief difficulties encountered have been of a mechanical nature, as moving parts have to be operated continuously at temperatures approaching a dull red. The worst obstacles are said to have been overcome, so that it is now possible to operate on a more or less continuous basis.

This is claimed to be an experimental installation only, but if it is found possible sufficiently to increase the throughput per unit of investment cost, it is intended to proceed with the installation of large operating plants.

The coke produced is a good grade of domestic fuel which is favorably received in the market. Under the present methods of operation about 20 per cent of the char goes through ½-in. mesh. Studies are under way to reduce the percentage of fines.

The KSG Low Temperature Carbonization Plant at New Brunswick, N. J. (Dr. R. P. Soule).

The KSG plant, which the International Coal Carbonization Co., a subsidiary of the International Combustion Engineering Corp., is building at New Brunswick, N. J., was described at length. Dr. Soule states that this plant is patterned after the successful KSG plant in Essen, Germany, where, since 1926, 50,000 tons of coal have been carbonized.

The New Brunswick plant will have a capacity of approximately 650 tons per day from eight retorts. A contract has been made with the Public Service Electric & Gas Company of New Jersey for the high calorific gas obtained from the process. This gas will be blended with blue water gas, the final mixture to have a heat value of approximately 550 B.t.u. The tar from the process is to be sold to the L. J. Lewis Company and the coke will largely be sold for domestic fuel.

It is announced by Dr. Soule that the Lukens Steel Co. of Coatesville, Pa., has contracted for a KSG plant of approximately 560 tons daily capacity. In this plant, which will be the first in this country in connection with a steel works, the gas will be used for the heat treatment of steel, instead of the raw producer gas now used.

These two KSG plants which, when completed, will be by far the largest in the world, indicate the extremely important advances made in the low temperature distillation field. They will be owned and operated by the International Coal Carbonization Co.

Dr. Soule states that approximately $20,000,000 has been spent in fruitless attempts to establish commercially successful plants, and he points out the need of very careful analysis of conditions before entering into large scale operations.

It should be noted that no claims are being made for the KSG system for the preparation of fuel to be used under boilers in power stations.

Low Temperature Carbonization of Coal by the Hayes Process.

A plant of the Hayes design has been installed by the Ben Franklin Coal Co. at their coal mines at Moundsville, W. Va. The first unit of 70 tons capacity was installed in 1927 by the Coal Carbonization Co. of Pittsburgh to produce a domestic fuel from slack coal, which amounts to 40 per cent of the coal mined. The slack is of very low price (approximately 75 cents per ton), and therefore a wide margin is available between the original fuel and the processed product. Another plant of 50 tons per day capacity was added in 1928.

The process is described in last year's report in a statement submitted by J. D. Davis of the Bureau of Mines.

The average yield of products from a ton (2000 lb.) of this coal is as follows, the process requiring 2,000,000 to 2,400,000 B.t.u. per ton:

Char (13,110 B.t.u.)	1430 lb.
Tar oil	29 gal.
Light oil	2.1 gal.
Gas (800 B.t.u.)	3750 cu. ft.

The char contains little moisture and is of a light friable character; it is readily crushed in preparation for briquetting or for pulverized fuel firing.

A still has been installed for the fractionating of the crude tar into light, medium and heavy oil, which is marketed as such. The remaining pitch is used as a binder for briquetting the char.

The cost of one 50-ton retort is approximately $50,000, with $150,000 for the auxiliary equipment. The retorts are made of a special steel that stands temperatures up to 2400 deg. fahr., although the furnace temperature is actually 1500 to 1600 deg. fahr. For a 300-ton plant, for instance, it has been estimated that the labor cost would be 50 cents per ton of raw coal.

Trumble Low Temperature Carbonization Process.

Distillation is effected in a series of retorts, using superheated steam as the heating medium. The raw material passes from storage bins into thermostatically controlled preheating chambers, where the raw material is preheated and de-hydrated by using the exhaust gases from the boilers and superheater. This preliminary de-hydration is stopped before gases are liberated.

From the preheaters the material is fed, by batch or intermittent delivery, into the distilling apparatus. This consists of a bank of retorts set in batteries of two. and each bank may consist of as many batteries as the practical application of the process through pilot plant operation has determined as being the most efficient combination for handling the material involved.

The superheated steam passes from the superheater through the first battery of retorts, and from there through the oil separator into the second interstage superheater. The temperature of the steam, vapors and fixed gases is again raised to the maximum temperature requirement. This mixture is now passed through the next battery of retorts, again giving up its heat to the raw material. The steam is reheated between each pair of retorts, the temperature being a little lower in each battery.

This cycle of heating is changed periodically and is so arranged that each successive battery of retorts receives its final cleaning from fresh superheated steam under pressure.

A pilot plant of semi-commercial capacity, 3.5 tons, has been built at Green River, Wyo., and is used for making practical demonstrations for the handling of the various oil shales found in the United States Another pilot plant has been constructed in Yokohama, Japan, for treating the coals, lignites and oil shales of Japan, Manchuria and Korea. These pilot plants have 12 retorts. The whole process of distillation takes 120 minutes; a retort is charged every ten minutes and the change in steam connections takes place in the same time interval, with a steam temperature range from 435 to 1050 deg. fahr.

It is estimated that on a 1000-ton basis the installation would cost $400 per ton daily capacity, or $600 including the refining equipment. For a 50-ton retort the cost is $600 per ton, or $750 including everything.

The "L and N" Process

The "L and N" Process and retort have been covered in detail in previous reports. This company has carried on extensive research work during the last few years in connection with their low temperature carbonization plant. The results of these investigations are given for the first time in Dr. Nielsen's paper. Data are given resulting from trials with a small test retort.

The "Plassmann" Low Temperature Carbonization Process—CTG Process.

The process has been developed specifically to use low grade, slightly coking coal, and to give as end product a lumpy coke. Distillation is continuous in a vertical retort, the coal being subjected to a pressure which may be varied to give the coke the desired compactness. Coke as produced by the Plassmann process can easily be shipped, and is claimed to be an ideal fuel, replacing anthracite, with the additional advantage that it ignites easily. Its ash content is high due to the nature of the raw product. Due to the subdivision of the flow of the heating gas, practically the same coking temperature prevails in all parts of the 18 coking chambers; the coke produced is therefore very uniform in structure and hardness. It can be crushed to any marketable size desired with only small losses in fines and dust (2 to

3 per cent). The coke contains 8 to 10 per cent of volatile matter.

Based on the favorable results obtained with a 1-ton experimental oven, a 50-ton retort was erected at the Prosper II mine, belonging to the Rheinische Stahlwerke in the Rhenish-Westphalian district, Germany, which has been in successful operation since the end of 1927. This oven has 19 heating chambers with a diameter of 13 ft., and 18 coking chambers. The height of each of the latter is 4 in., reducing the coking period to approximately 5 hours. The overall dimensions of the oven are 15 ft. diameter and 20 ft. high. The 18 coking chambers have a volume of 425 cu. ft. Aspirated fines up to 1 mm. (0.04 in.) size are carbonized.

A large plant of the Plassmann design is being erected near London. Three retorts of 65 tons capacity each are already in course of construction, and the plant is to be enlarged gradually. The coking properties of the English coals had been determined in a 2.5-ton experimental oven erected for this purpose in England.

The cost of a 50-ton retort is estimated at $80,000.

The Turner Carbonizing Retort.

This process differs from the previous ones described mainly in that it uses highly superheated exhaust steam to heat the raw coal.

The plant consists of a superheater for delivering the necessary steam to the bottom of a vertical retort. The latter is equipped with valves, to allow continuous charging and discharging. The gas outlet is fitted with a valve which opens at a particular pressure and remains open until the pressure has dropped to a fixed lower pressure. A tubular condenser is used to condense the vapors passing through the valve from the retort.

In the experimental retort at Poynton 32 different materials, including peats, lignites, oil shales, cannel coals and bituminous coals have been treated; only the last named has offered any difficulties. Some of the worst coals had to be treated for 12 hours in the retort, while the best of non-melting coals required only 2 hours with steam temperatures up to 600 deg. cent. (1110 deg. fahr.).

The solid residue or char, which is 70 per cent of the original weight, is thrown into cold water. The portion that floats, consisting of over 50 per cent of the original weight, is sold. The residue is used in the gas producers or under the steam boilers.

Yields of oil that have been obtained are: Peats, up to 20 gal. per ton of coal; lignites, up to 60; oil shales, up to 80, and with bituminous coals, up to 45.

For treating one ton of bituminous coal, one ton of steam at 650 deg. cent. (1200 deg. fahr.) is required.

Low temperature distillation of Briquets by Superheated Steam, Weiss System.

A plant of this type has been in operation since 1926 at the mines of the Compagnie des Mines de Vicoigne, Noeux et Drocourt, France. The first consideration in erecting and operating this plant was to produce a substitute for anthracite.

Coal dust is agglomerated into ovoid balls with pitch or asphalt as a binder. These balls are put into a series of stationary chambers of a capacity of 20 tons each, and heated progressively with steam superheated to approximately 1200 deg. fahr. The steam is then condensed in order to permit the recovery of the primary oils and tars, the gas and the major portion of the binder. Exhaust steam from the main turbine-generators is used, re-superheated in specially designed superheaters before entering the distillation chambers. The method of heating somewhat varies, depending on the raw coal.

The product of this process is sold for domestic use under the trade name of Anthracine.

The installation at Noeux consists of eight sheet-iron cylindrical chambers arranged around a central distributor. The chambers have a diameter of 11.5 ft. and a height of 18 ft., divided into compartments by specially shaped rings. The rings are arranged in such a way that the pressure on the briquets does not exceed permissible limits anywhere in the retort, thereby preventing deformation of the balls during the softening period.

The present capacity of the plant is 200 tons per day with a normal production of 150 tons. New steam generators are being erected at present to increase the total capacity to 400 tons.

It is stated that the cost of a plant of the Weiss type is somewhat less than that of a high-temperature coke-oven plant of the same capacity, and that the total cost of distillation will be between $3 and $3.50 per ton of marketable briquets. This figure applies to a plant of 300 to 400 tons capacity per day, using coal containing less than 18 per cent volatile matter and including all the costs for labor, maintenance, repairs, motive power and amortization; it likewise takes into account the recovery of the by-products.

The Transformation of Fine Bituminous Coal into Substitutes for Anthracite, Trent Process (A. Leaute).

The fine coal is formed into briquets before distillation, the binder used for agglomeration being chosen with consideration of the role it is to play during the distillation. The author goes into considerable detail as to the desired characteristics in the finished product in order to compete with natural anthracite.

The process is being used at present on an industrial scale at Lapugnoy; the present capacity is 50 tons of artificial anthracite a day. The installation consists of a Trent cleaning plant, a mixing and agglomeration plant and a distillation plant.

The distillation furnace consists of several chambers heated on the interior by steam superheated to 600 deg. cent. The crude artificial fuel is in buckets which are moved by hydraulic means from chamber to chamber, to subject them to the proper heating. The rate of heating can be regulated with great precision. The thermal efficiency is raised by closed circuit operation.

The International Bitumenoil Corporation Process.

The retort used in this process is of the inclined rotating tubular type. Novel features claimed are accurate zoning of the heat in separate furnace compartments along the tubular retort, methods of withdrawing vapors, introducing gases, feeding and discharging material, condensing volatile products and air sealing.

It is claimed that the methods and apparatus are conveniently flexible and adapted to widely varied treatments and results in processing a great variety of materials. The charge in the two preheating zones is heated to from 500 to 700 deg. fahr., and to from 900 to 1000 deg. fahr. in the fourth or carbonizing zone, with intermediate temperatures in the third or intermediate zone.

Of the 6000 to 8000 cu. ft. of high B.t.u. gas ordinarily recovered in the process, less than 2000 are used for distillation purposes. High oil recovery is claimed, with a maximum of 62.5 gal. per ton of Tennessee cannel coal.

A contract has been closed in England for a plant of 2000 tons ultimate daily capacity, the initial installation being for 600 tons. American interests are starting a smaller installation in Tennessee.

Two economic set-ups are submitted, one showing the application of the "International Bitumenoil Process" to cannel coal and one its application to bituminous coal. Both show a large net return resulting from small capital charges and very low cost of the raw product. A 400-ton plant is estimated to cost $300,000.

A New System of Coal Carbonization (Julien Pieters).

The Pieters carbonization process is a progressive and continuous one, starting at about 212 deg. fahr. and finishing at 1470 to 1740 deg. fahr., according to the quality of coke required. The coal passes through the zones of low temperature, intermediate and high temperature carbonization in succession.

Laboratory tests showed that such a process could only be conducted in a vertical continuous retort. A trial oven of 10 tons capacity was built in 1919, and an improved type of the same capacity in 1925 in Belgium.

The raw coal before entering the retort is ground into a fine powder, briquetted, and during the coking process is kept under pressure. In general, slow and progressive distillation improves the quality of the coke, as rapid distillation tends to break it up. Dry coal is agglutinated by adding oxidized pitch.

The oven is said to differ from other coke or gas ovens in the following respects:

1. Continuous recuperation with very low temperature of the leaving flue gases.
2. System of progressive operation.
3. Special flue construction, which allows quick firing and rapid decrease of temperature from bottom to top.
4. Special discharging system.
5. Special treatment of all combustibles, producing, after recovery of all byproducts, a new fuel having all the characteristics of metallurgical coke or anthracite, even from fuel of a non-coking nature. The coke is produced in a definite form and size and no breeze is obtained.

The following table shows a comparison between the Pieters process, a high temperature and a low temperature process. (In reference to the latter it should be noted that the author assumes that all the gas generated is used up in the process, although most low temperature processes yield surplus gas that may be sold.)

COMPARATIVE RESULTS OF THE CARBONIZATION OF A BITUMINOUS COAL WITH 35 PER CENT VOLATILE, BASED ON 2240 LB.

Low Temperature Distillation of High Moisture Coals (F. Seidenschnur).

Professor Seidenschnur reports on the results that he has obtained in the low temperature distillation of high moisture combustibles, especially of earthy fine-grained German lignite and lignitic lump browncoal. These results led to the perfection of the Freiberg Process. Particular attention must be paid to the drying process of high moisture coals.

Low Temperature Distillation, The British Coal Industry and Oil Supplies (R. H. Crozier).

The importance of low temperature distillation to Great Britain is shown. The author discusses the modern trend toward reorganization of the coal industry along rational lines. It is predicted that raw coal will decrease in importance while the importance of low temperature distillation products will increase. Statistics quoted show the production and consumption of coal in Great Britain, and the amount of products potentially recoverable through low temperature distillation of coal and also gives the oil resources of the British Empire. It is suggested that the treatment of a million tons of coal and the oil shales yearly, involving development of an industry of unprecedented magnitude, must be undertaken promptly for Great Britain to be in position to face an inevitable oil shortage.

Low Temperature Carbonization (C. H. Lander).

The paper shows that considerable progress has been made both by the Fuel Research Station and by industry in the solution of the low temperature carbonization problem as it affects Great Britain. A warning is sounded against both groundless optimism and unnecessary pessimism concerning the prospects of low temperature carbonization. Information on the subject is rapidly being made available by the Fuel Research Board and by many firms and individuals engaged on the problem, and it is pointed out that special local conditions exist in various parts of the world in which one or another of the plants developed can be expected to be commercially profitable. The author suggests that only experience can tell to what degree the process may develop as a really large industry and an important factor in the economy of the world's fuel.

Some Fundamentals of the Carbonization of Coking Coals: The Formation of Cenospheres (F. S. Sinnatt).

The paper is a study of the fundamental structure of coke and deals particularly with the carbonization of coal in the form of small particles. When particles of coal of a critical magnitude are subjected to heat treatment, hollow spheres, called cenospheres, are produced. The spheres are characterized by a lattice structure with the spaces covered with thin bubble-like films (called windows), black by reflected light and colorless to dark brown by transmitted light, and minute specks of material best seen in the transparent portion. The formation of cenospheres has been used to prove that different parts of the same coal seam may possess widely different swelling properties. Some particles do not swell, and others form cenospheres having 40 times the volume of the original particles of coal from which they were produced. Cenospheres have been found in quantities in the dust from various types of industrial plants (locomotives, cement works, etc.), and their low specific gravity accounts for the fact that dust from industrial furnaces may be found at considerable distances.

The Influence of Inorganic Materials in Lignite Carbonization (A. W. Gauger).

The pioneer work of Dr. R. Lessing on the influence of mineral matter in the carbonization of organic materials has been extended in a study of North Dakota lignites. Not only is the amount of char and tar affected by the presence of inorganic material, such as iron, aluminum chlorides and aluminum sulphates, but also the very nature of the char as well. Lignites ordinarily slack in the fire, and on carbonizing produce a loose, non-adherent semi-coke or char. If such carbonization is carried out in the presence of aluminum chloride or sulphate, a hard adherent pseudo-coke is formed instead of the usual loose char. In some cases this pseudo-coke possesses a silvery metallic luster resembling that of coke and gives a metallic ring when struck.

By-Products

A number of papers were delivered at the Pittsburgh conference relating to byproducts obtained from the carbonization process, among them the following: "The Tar Industry in France," Jean Bing; "Some Phases of the Organic Sulphur Problem in the Manufacture and Utilization of Gas," Wilbert J. Huff; "Gas Purification in Relation to Coal Sulphur," F. W. Sperr, Jr.; "Continuous Distillation of Coal Tars and Crude Oils by Superheated Steam by the Ab-Der-Halden Process," J. V. Henri Winkler; "The Cracking of Low Temperature Coal Tars," Dr. A. E. Dunstan; "Cracking of Tar Acids from Coal," Jacque C. Morrell and Gustav Egloff; "Extraction and Recovery of Phenols from Ammonia Liquors," Robert M. Crawford; "New Catalytic Processes for the Utilization of Coal Tar Crudes," Dr. Alphons O. Jaeger; "Formation of Benzol and Other Hydrocarbons by the Action of Heat on Methane," Franz Fischer, and "A Study of Comparative Costs of Gas Production in the Retort House," E. W. Smith.

A paper was given by Dr. Pott, relating to the recent extensive development in Germany of a pipe line system for carrying coke oven gas over a considerable territory for interconnecting producing and consuming centers. This development is of general interest, and the paper is abstracted below.

Transmission of Coke Oven Gas in Pipe Lines in Germany, Dr. Ing. e.h. Alfred Pott.

The Ruhrgas Corporation of Essen, founded in 1926, has as one of its main purposes, the distribution of gas from the Rhenish-Westphalian industrial district to neighboring and distant cities and communities. Ten billion cubic meters of coke oven gas are produced yearly in the Ruhr district. Until recently this has been largely consumed in heating coke ovens and firing steam boilers. Owing to recent progress in fuel engineering, cheaper fuels, such as low grades of coal and coke can now be used for the heating of boilers and coke ovens, etc., reserving the valuable coke oven gas for more profitable purposes.

The pressures at which the coke oven gas must be conveyed in the pipe lines depend on the quantity of gas and the distance. Large quantities of gas should be pumped at a pressure of 3 to 6 atmospheres for small distances; for longer distances it should be compressed up to 12 to 20 atmospheres in intermediate compressor stations. The diameters of pipe lines are proportioned to the gas volume and distance, ranging from 400 to 700 mm.

The author reports in detail the present status of line construction, the crossing of streets, rivers and railroads, methods of pipe welding, the application of couplings and connections. Modern technical methods and developments of the last year and a half that have proved especially valuable are mentioned. The protection of the lines against corrosion and electric currents, as well as the methods of supervision, measurements and recording along the lines, is mentioned.

By the end of 1929 a pipe line network aggregating 950 km. will be available, which will supply with gas an area of 11,000 sq. km. having a population of 10,000,000 people. The gas consumption in this area will, by the end of next year, amount to two billion cubic meters. Improvements at the coke plants in the Ruhr district make it possible (because of the large quantities of gas—totaling 400 to 500 million cubic meters per year) to clean, compress and measure gases at the individual mines. This reacts favorably upon the economical results of the overland gas distributing system.

The compression of the gas is effected by steam-driven piston compressors. It is cleaned of sulphur by the dry cleaning process using iron ore or similar material. For overland transportation the naphthalene is completely removed from the gas by a new process, in which pressure and temperature conditions during the compression of the gas are fully utilized.

The gas coming from the large coke oven plants has a uniformity in heat value and density that has never before been attained; by employing a new method, the gas can be turned out at a specific heating value and density if this should be desired. For this purpose a part of the coke oven gas is mixed with water, steam, air or carbonic acid, and this mixture is then added to the original gas in the necessary quantities.

With all these improvements the overland supply of coke oven gas can be accomplished successfully, economically and with the greatest safety, and the maximum energy economy of the coke oven gas can be realized.

Hydrogenation

A number of papers on hydrogenation and related subjects, including a complete classification of fuel, were delivered at the conference, among them the following: "New Aspects of Coal Economy," Dr. J. G. Aarts; "Hydrogenation at High Pressure and High Temperature With or Without Catalyzing Agents," Dr. Andre Kling; "Some Aspects of Hydrogenation," J. Ivon Graham; "The Hydrogenation of Coal Tars," Prof. G. Hugel; "A New Method for Direct Determination of the Best Temperatures of Hydrogenation for Bituminous Coals," J. P. Arend; "Catalysis Applied to the Conversion of Hydrocarbons," Dr. Carl Krauch, and "Transformation of Cellulose and Lignite into Coal," Dr. Friedrich Bergius.

Influence of binding material upon distillation of long flame coal; porosity of residue can be avoided by using anthracene oil as binding material which has minimum content of tar; residue is then hard and compact, similar to anthracite and can be used as such.

HIGHER STEAM PRESSURES AND TEMPERATURES

SUMMARY

The past few years have demonstrated the practicability of operation and the thermal economy of the 1200-lb. cycle.

This report contains statements on stations that have operated at the above pressure for some time, and on a number of new installations.

It is interesting to note that only a few years ago the Higher Steam Pressures and Temperatures Subcommittee's report included data on 300-lb. and 400-lb. installations; whereas, this issue contains nothing below 600 lb., and the majority of data are on installations of 1200 lb. or over.

This increased use of higher pressure is due, to a large extent, to the untiring effort of the A. S. M. E. Committee on Steam Research.

Steam temperatures have not kept pace with steam pressures. Temperatures of 650 to 700 deg. fahr. have been common with 300 and 400 lb. units; whereas, 750 to 775 deg. fahr. seems about the present practical limit for 1200-lb. installations in this country. The possible reason for this is found in a statement on The Behavior of Metals at Elevated Temperatures, submitted by Prof. A. E. White.

The rapid acceptance of the 1200-lb. cycle as economical and practical has opened the way to still higher pressures, and a study of their thermal possibilities is not only of interest but quite timely.

What the future holds in the design of higher pressure and temperature equipment is well brought out in a statement on Higher Pressures and Temperatures which C. F. Hirshfeld has contributed.

The probable relation of caustic embrittlement to higher pressures and temperatures and the desirable carbonate-sulphate ratios are covered by a statement on The Relation of Embrittlement to Higher Steam Pressures and Temperatures, by Prof. F. G. Straub.

A section of this report contains data on the relative construction costs of 400 and 1200-lb. equipment.

Manufacturers' statements also are included. The rapid increase in the use of welded vessels for high pressure service is made evident by some of these statements.

RECENT INSTALLATIONS

While two of the larger central stations in this country have operated at 1200-lb. pressure for several years, the year 1928 has shown the first stage in the more general adoption of high-pressure equipment, as evidenced by the following new or proposed installations. These stations are the 1250-lb. Holland Station, the 1200-lb. Deepwater Station and the 1200-lb. South Amboy Station (representing the first large stations originally designed for high pressure), the 1400-lb. addition to Northeast Station, Edgar Station, Lakeside Station and the 1800-lb. installation for the Philip Carey Co.

In addition to the above, several new 600-lb. and 700-lb. installations have gone into service or are under construction, namely, State Line Power Station, the addition to Powerton Station, the Grand Avenue Station (Kansas City), and the 650-lb. installation of the Waldorf Paper Products Co.

OPERATING COMPANIES' STATEMENTS

STATEMENT BY W. S. BARSTOW & COMPANY, READING, PA.

Holland Station, Holland, N. J.

The new 1250-lb. pressure Holland Station of the Pennsylvania-New Jersey Power System is being constructed at Holland, N. J., on the Delaware River by W. S. Barstow & Co. It will be the main Eastern generating station of the system.

The throttle steam conditions will be 1250-lb. gage, 750 deg. fahr. total temperature. Before adopting 1250 lb. as the operating pressure, studies of 400, 600 and 1250-lb. plants were made, and based on coal between $4 and $5 per ton and 50 per cent load factor. The 1250-lb. plant was selected as the most economical, considering combined operating and investment costs.

The first unit of the station will consist of a 55,000-kw., General Electric Company cross compound turbine generator unit consisting of an 11,800-kw., 85 per cent power factor, 13,800-volt, high-pressure element, operating at 3600 r.p.m., and a 43,200-kw., 85 per cent power factor, 13,800-volt, low-pressure element, operating at 1800 r.p.m., with direct-connected exciter of sufficient capacity to excite both generators.

At the time the Holland Station was considered, all 1200-lb. pressure installations in operation or considered at that time were arranged as an increment to an existing plant, allowing the high-pressure unit to be operated upon base load conditions. In the Holland Station is was necessary to design the plant for variable load operation, and it was realized that to build a 1250-lb. station for higher efficiency and variable load operation, the high-pressure element of the turbine must be of the multi-valve type to provide a greater range of expansion at fractional loads, and that means for maintaining a constant reheat temperature would have to be obtained. After discussing this matter with the turbine manufacturers, it was arranged to design the high-pressure unit having five steam admission valves.

Two steam-generating units will be provided, each having a capacity of 250,000 lb. of steam per hour at 1400 lb., 750 deg. fahr. and reheat at approximately 400 lb. and 750 deg. fahr. These units will consist of:

7928 sq. ft. B & W boilers.
5520 sq. ft. superheaters.
11,450 sq. ft. B & W gas reheaters.
1508 sq. ft. B & W steam reheaters.
11,880 sq. ft. Foster Wheeler economizers.
32,450 sq. ft. Foster Wheeler air preheaters.
2194 sq. ft. water walls and screens, boiler No. 1, bottom screen—plain tubes; front, rear and side—fin tubes.
1866 sq. ft. water walls and screens, boiler No. 2, front, rear and bottom—plain tubes; side—fin tubes.

Reheaters are integral with the boiler unit and the reheat temperature held constant throughout the entire range of operation by means of a first stage steam reheater.

Steam from the boiler flows to the convection superheater and thence to the high-pressure section of the turbine which exhausts to the steam reheater operated in series with a flue gas reheater, and is returned to the low-pressure section of the turbine. Saturated steam from the boiler is used in the steam reheater for supplying the heat, and constant re-

heat temperature is obtained by thermostatic regulation of the steam to the steam reheater, the proportions of the two reheaters being so arranged that at full loads the steam reheater is nearly cut out, the flue gas reheater furnishing all the heat required.

The bin system of pulverized fuel will be used. Mill drying will be applied, the vents from the mills being used for secondary air supply to the burners; this eliminates the objectionable dust features of this design. The furnace is designed for a heat liberation of 20,000 B.t.u. per cu. ft. at 250,000 lb. of steam per hr. Opposed firing will be used, with three burners on each of two opposite sides of the furnace. The side walls are of the fin tube type, but the two walls carrying burners are protected by bare tubes set in the brickwork above the burners. The furnace is equipped with a special water screen above a dry ash pit of new design. The ash pit arrangement is so laid out that it can be changed to a slag tap bottom if desired at a later date without major or costly changes. The plant is designed so that all fuel can be pulverized during the off-peak period.

The heat cycle and arrangement of the auxiliary equipment was decided upon after carefully balancing the economies and first cost of various equipment. This arrangement is indicated in the heat cycle diagram, Fig. 1.

The condensate, after leaving the condenser, is first pumped to a surge tank with a float valve control, which may divert it to an evaporated water storage tank. From this point the condensate or feed water is delivered to the boiler through three separate pumps acting in series. The first pump delivers it to the deaerating heater after it has passed successively through the first stage heater supplied with steam from the 15th stage of the low-pressure turbine, a small vent condenser and the evaporator condenser. The second pump forces the water through a third and fourth stage heater, taking steam respectively from the 6th stage of the low-pressure turbine and the exhaust of the high-pressure turbine, while the third pump, working against a maximum head of 1600 lb., takes the water which has now reached a temperature of 430 deg. fahr. at full load and discharges it to the boiler through the economizer. This fourth stage heater is so arranged that it can be used as a desuperheater should it be desired to operate the low-pressure turbine only.

With four stages of steam extraction employed, the condenser is considerably reduced in size, there being only a little over 0.7 sq. ft. of condensing surface per kw. capacity of the low-pressure section of the turbine. It will be of the single-pass type with horizontally divided water boxes, and will be arranged for reversing the circulating water flow. The tubes will be expanded into both the inlet and the outlet tube sheets and expansion and contraction cared for by expansion joints adjacent to the tube sheets.

Inasmuch as the Holland Station is connected by means of four high-tension and two low-tension circuits, all of the auxiliaries will be motor driven with the exception of one feed pump. The control of the station will be centralized at one point which will materially reduce the operating personnel required. The wall which usually separates the turbine room from the boiler room will be omitted in order to allow the control operators a greater range of vision.

Fig. 2 shows a plan and Fig. 3 a cross section of the first section of the Holland Station.

Construction work on the station is progressing rapidly. The intake and discharge tunnels and all foundations and part of the building have been completed.

It is expected that the station will go into operation about October, 1929.

STATEMENT BY THE UNITED GAS IMPROVEMENT CO., PHILADELPHIA, PA.

Deepwater Plant

As noted in the 1927-28 Report of the Subcommittee on Higher Steam Pressure and Temperatures (N. E. L. A. Publication No. 278-53) there is being built jointly for the United Gas Improvement Company and the American Gas & Electric Company at Deepwater, N. J., on the Delaware River, a plant to operate at approximately 1200-lb. pressure. This plant is now under construction and is expected to be ready for operation in November, 1929.

The principal items of equipment to be installed in this plant are:

Two 53,000-kw. General Electric cross compound turbo-generator units, each set consisting of one 12,500-kw., 80 per cent power factor, 3600 r.p.m., high-pressure element, and one 41,700-kw., 85 per cent power factor low-pressure element, each generator having its own direct connected exciter. The low-pressure element of each unit is served by a 42,500 sq. ft. Foster Wheeler single-pass surface condenser.

One 12,500-kw. General Electric high-pressure unit, similar to the high-pressure element described above, for furnishing steam to the adjacent plant of the Dupont Company.

Four Standard steam-generating units, each capable of producing 331,000 lb. of steam per hour at a total temperature of 725 deg. fahr. and a nominal gage pressure of 1200 lb., and consisting of:

One 9000 sq. ft. Babcock & Wilcox boiler; one 18,326 sq. ft. Babcock & Wilcox economizer; one 46,600 sq. ft. Foster Wheeler air preheater.

Two reheat units each capable of generating at maximum capacity 290,000 lb. of steam per hour and consisting of:

One 9000 sq. ft. Babcock & Wilcox boiler; one 25,155 sq. ft. Babcock & Wilcox reheater; one 4765 sq. ft. Babcock & Wilcox economizer; one 52,800 sq. ft. Foster Wheeler air preheater.

The boilers are fired with pulverized fuel, three by the unit system and three by the bin system. Slagging type furnace bottoms will be used.

The three unit system fired boilers will each have 1781 sq. ft., projected area, of bare tube water walls, and 721 sq. ft. of Bailey blocks, while the three bin system fired boilers will each have 1797 sq. ft., projected area, of bare tube water walls, and 342 sq. ft. of Bailey blocks.

The turbines are bled at four points for feed water heating, and the best point turbine room heat rate is estimated to be 9350 B.t.u. per kw-hr., as indicated on the heat balance diagram, Fig. 4.

FIG. 6—SECTION VIEW, B & W 1400-LB. REHEAT BOILER, DEEPWATER STATION.

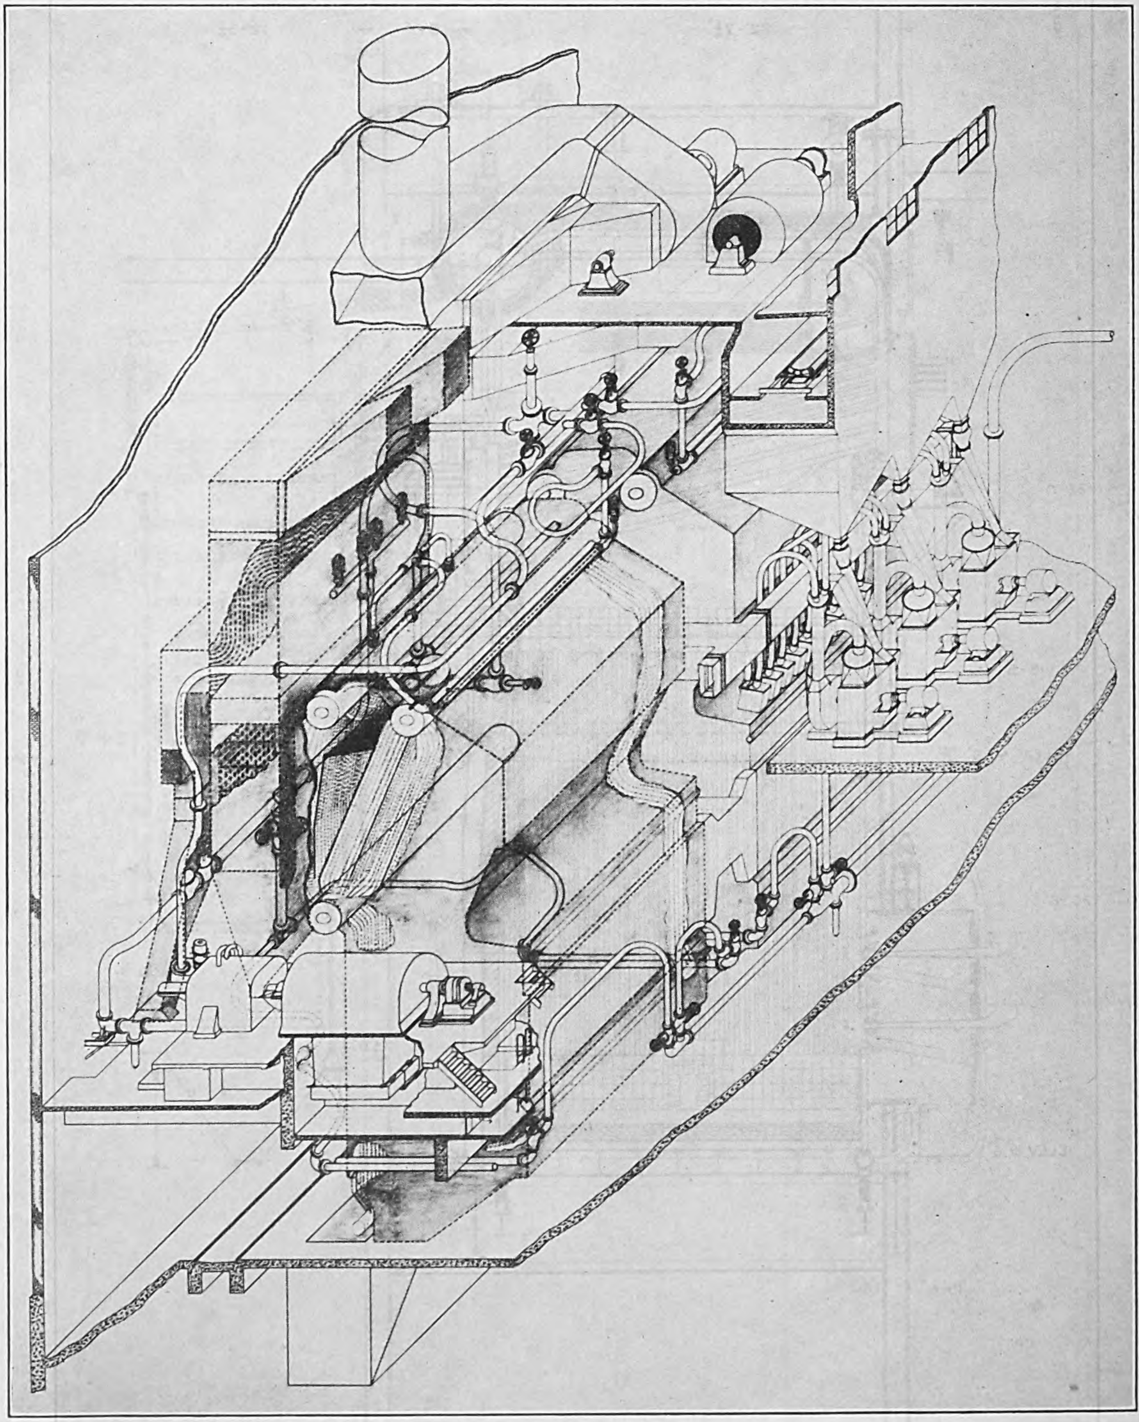

FIG. 7—ISOMETRIC VIEW, 1400-LB. INSTALLATION AT NORTHEAST STATION.

STATEMENT BY THE KANSAS CITY POWER & LIGHT COMPANY

Northeast Station

The 1400-lb. boilers and turbine recently installed at Northeast Station were put into service the first of this year.

Briefly, the installation consists of two 1400-lb., 16,950 sq. ft., three-drum Sterling type boilers, equipped with economizers, air heaters and water-cooled furnaces, each fired directly by three No. 90 unit Imp mills, of 45,000 lb. total capacity, supplying steam to a 10,000-kw., 1200-lb. Westinghouse turbine, comprising two rows of impulse and fourteen rows of reaction blading, which exhausts through reheaters in the above boiler side walls to the 300-lb. station header. Details of this equipment will be found under the manufacturer's statements in this report, and also in a paper presented Feb. 15, 1929, by Edwin Jowett at the Fourth Midwestern Engineering and Power Exposition.

Fig. 31 shows a cross section through the boiler unit, and Fig. 7 an isometric view of the boiler and turbine installation, indicating the close proximity of the boilers and turbine, which simplified piping and reduced pressure drops.

A condensate flow diagram, Fig. 8, shows the high-pressure boilers receive feed water from a surge tank supplied with condensate only, the system make-up going into the surge tank supplying the 300-lb. boilers. This should help to minimize boiler feed water trouble in the high-pressure boilers.

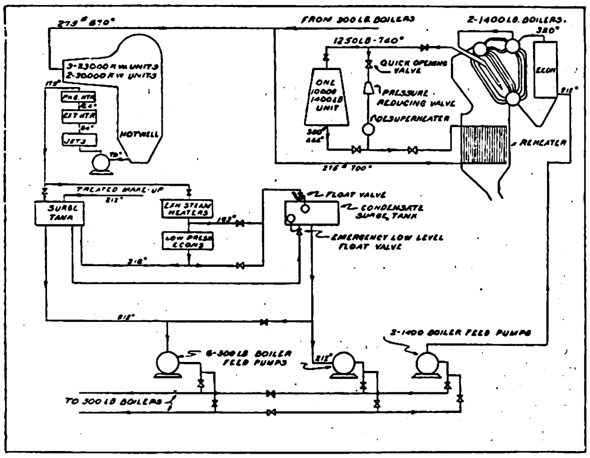

FIG. 8—CONDENSATE FLOW DIAGRAM, NORTHEAST STATION.

Fig. 9 shows one of the two boiler control boards on which are mounted the controls for the pulverized coal mills, the coal feed motors, fans and damper controls; also the boiler header, reheater, quick opening by-pass and pressure reducing valve controls.

Normally the quick opening valve will open automatically if the high-pressure turbine throttle or generator unbalance protective relays trip. This permits steam from the high-pressure boilers to by-pass the turbine and flow through the pressure reducing valve desuperheater and reheaters to the 300-lb. header, thereby supplying steam to the 300-lb. turbines, enabling them to pick up the load dropped by the high-pressure unit.

The control boards also contain electrical temperature recorders, indicating the gas, feed water and steam temperatures, together with a steam-air flow meter, draft gages, pressure gages and ammeters, indicating the load on the mills, fans and coal feed motors.

The boiler units are hand controlled at present, but are so arranged that automatic control can be installed at a later date if deemed advisable.

The completion of this installation has been retarded due to numerous delays in the manufacturing and delivering of equipment, and at the time of making this report they have only had several preliminary runs. The chief difficulty encountered during these runs has been the blowing out of a number of soft fiber gaskets. These have been replaced with metal gaskets which have given no further trouble.

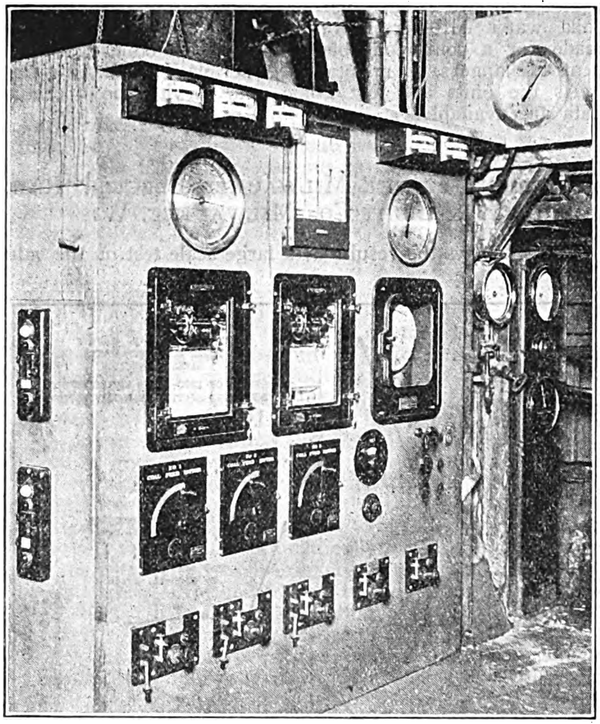

FIG. 9—BOILER CONTROL BOARD, NORTHEAST STATION.

Some tube roll leakage has been experienced in the bottom drums. This was attributed chiefly to the difference in temperature created by the feed water entering the lower drum and being fed up through the last four tube banks. The method of feed will be changed to enter the top rear drum.

The installation of the feed water regulators has not been completed as yet, but hand control is not difficult, and while the units are more complicated than a standard boiler unit, no serious difficulties have been encountered in their operation to date.

Only preliminary performance data have been taken at this time, which is not complete or reliable enough for publication.

Grand Avenue Station

At the time of writing this report, one of the three new 700-lb. boilers at Grand Avenue Station has just completed its first preliminary run, delivering steam through the pressure reducing valve and desuperheater to the 185-lb. station header.

Briefly this installation consists of three 700-lb., 15,160-sq. ft. Sterling type, three-drum boilers, equipped with economizers, air heaters, water-cooled furnaces, Green forced draft chain grate stoker, 24 ft. wide x 22 ft. long, delivering normally 150,000 lb. of 740 deg. steam to a 10,000-kw., 80-per cent power factor General Electric Co. turbine.

Details of this equipment will be found under the manufacturer's statements.

This turbine exhausts at 185 lb. and about 125 deg. fahr. superheat to the low-pressure boiler header which supplies steam to two 10,000-kw. horizontal and two 15,000-kw. vertical turbines. During the heating season part of this 185-lb. steam will be used in carrying the commercial steam heating load, none of this condensate being returned to the system.

Because of the large amount of make-up during the heating season, two 28,000-g.p.h. Cochrane hot process lime and soda water softeners have been installed, and provisions made for a continuous blowdown of the boilers, through heat exchangers, to maintain the permissible concentration.

As the units are just going into service, no operating data are available.

STATEMENT BY THE MILWAUKEE ELECTRIC RAILWAY & LIGHT CO., MILWAUKEE, WIS.

Fig. 10 shows the results of a large scale test on the value of high-pressure equipment installed in a 300-lb. pressure station. Overall station heat consumption is reported for successive months under following conditions:

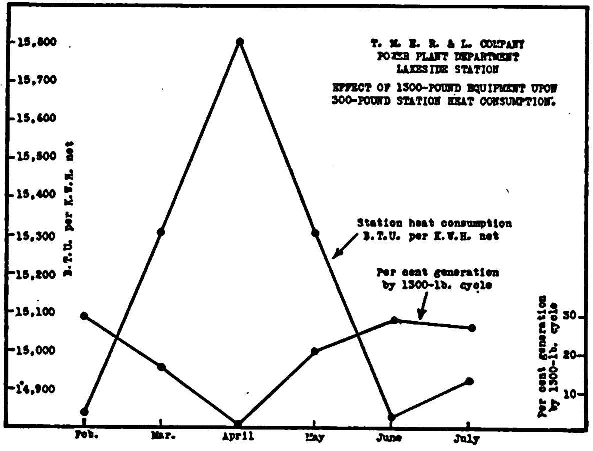

FIG. 10—EFFECT OF 1300-LB. EQUIPMENT UPON HEAT CONSUMPTION, LAKESIDE STATION.

Month No. 1—1300-lb. equipment in continuous operation with 300-lb. equipment.
Month No. 2—1300-lb. equipment in operation with 300-lb. equipment half of month.
Month No. 3—Only 300-lb. equipment operating.
Month No. 4—1300-lb. equipment in operation with 300-lb. equipment half of month.
Month No. 5—1300-lb. equipment in continuous operation with 300-lb. equipment.

Results are shown by the curve, Fig. 10, and other significant data are given in Table I.

The actual station economy data would indicate approximately 20 per cent better efficiency with the 1300-lb. equipment than the 300-lb. equipment. With outage of the high-pressure turbine, the 300-lb. equipment is handicapped slightly by operation of the high-pressure boiler throttling its steam to 300 lb. Other calculations show the difference in efficiency to be 16 per cent.

TABLE I

EFFECT OF HIGH-PRESSURE EQUIPMENT ON LAKESIDE STATION EFFICIENCY

1 Month, 1928	Feb.	March	April	May	June	July
2 Days operation of h.p. turbine	29	16	0	19	28	29
3 Per cent station output gen. by h.p. turbine	6.72	3.74	0	4.66	6.45	6.13
4 Per cent station output gen. by h.p. cycle	29	16	0	20	28	27
5 Overall station heat consumption, B.t.u. per kw-hr.	14,844	15,310	15,812	15,306	14,831	14,932
6 Per cent lower heat consumption than April	6.1	3.2	......	3.2	6.2	5.6
7 Apparent higher efficiency 6o h.p. cycle (No. 4 No. /f100)	21	20	....	16	22	20

The two months' turbine outage was occasioned by a warped shaft resulting from the use of highly efficient but unreliable interstage packings. Since installing standard seals operating continuity has been as shown in the first column. Yearly data are given in the second column:

Period	May to Dec., Incl., 1928	Year 1928
Elapsed hours	5,880	8,761
Boiler hours	5,035	6,945
Boiler use factor	86	79.4
Turbine hours	4,785.2	5,993.6
Turbine output, million kw-hr.	30.97	39.23
Turbine use factor	81	68
Turbine load factor	75	64.5

During the eight months' period from May to December, the boiler was opened once, in September, for an inspection.

The year's run verifies the reliability and economy of 1300-lb. equipment.

Details of Operating Experiences

The method of feed water control has been proved adequate to allow indefinite operation of the boiler unit without internal cleaning. Raw water make-up has averaged 0.2 per cent over the entire operating period since new, and occasionally condenser leakage of 0.5 per cent has been encountered over a week's operation. On one occasion, 2 per cent condenser leakage was treated successfully for a short period. Chemical treatment is based upon the amount of raw water passing into the boiler, and final results are the same, provided treatment and blowdown are proportional to the raw water make-up.

The 1200-lb. pressure turbine has not been affected in capacity nor efficiency since the original elimination of deposits on the blading. It is carrying its full rated capacity of 7000 kw.

The high-pressure boiler feed pumps have not proved entirely satisfactory. They increased boiler feed water pressure from 300 to 1400 lb. The water temperature is 330 deg. fahr. Thrust troubles have so affected interstage clearances that leakage has gradually increased and requires periodic maintenance of the interstage labyrinths. New type thrust bearings are being furnished by the manufacturer. Erosion of the bronze impellers has prompted installation of steel ones.

High-pressure extraction heater tubes have gradually become eroded at the entrance ends where the water temperature is 300 deg. fahr. or above. There have been failures of several individual tubes due to lack of uniformity in grain structure. It appears that use of tubes made from special metals, in cases where pressures above 300 lb. and temperatures of 300 deg. fahr. occur, is warranted.

The high-pressure equipment has necessarily carried its full quotation of station load over the recent winters, and from all standpoints has proved its commercial value. A second boiler unit has been purchased, and plans for the quite near future contemplate installation of two more boilers and attendant high-pressure turbines.

STATEMENT BY THE EDISON ELECTRIC ILLUMINATING CO. OF BOSTON

The information contained in this statement applies only to the new higher-pressure equipment contained in the recent addition to the Edgar Station, except where specifically noted. The new equipment consists of two 1400-lb. boilers with integral reheaters, one 10,000-kw. 1200-lb. turbine, two 500-lb. and three 1600-lb. boiler feed pumps.

Operating Experiences

Boilers

The load factor on these boilers has been approximately 40 per cent since installation; the limiting factors which are gradually being eliminated are excessive burning and breakage of stoker parts and the bursting of superheater and water wall tubes due to poor circulation. The performance of the firing equipment has generally been unsatisfactory. The boilers have never been taken off the line because of feed water conditions or treatment. Aside from some gasket trouble experienced at the start due to poor workmanship, the economizers have given practically no trouble. Until our stokers are free of trouble we are using our automatic boiler control only for pressure regulation. To date (Feb. 9, 1929), the longest continuous run including banked hours of one boiler is 170 hr. and the other 459 hr.

Boiler maintenance has required the following tube replacements in the two units during the first year of service:

Boilers—4—(bagged)
Superheaters—8—(7 due to poor steam distribution)
Economizers—None
Reheaters—None
Water walls—55—(two burst, 53 in poor condition)

The replacement of tubes is no more difficult in high-pressure boilers and takes practically no more time than in lower-pressure boilers. The metals used in the tubes are apparently satisfactory as regards both durability and suitability. The only failures have been caused by poor circulation and steam distribution. The manufacturers have taken steps to prevent the recurrence of these troubles.

The safety valves on the high-pressure boilers have shown the same degree of tightness as those on the lower-pressure boilers.

It has not been noted in operation that higher-pressure causes any ineffectiveness in heat saving devices.

The designed pressure drops and steam velocities are given in Table II.

TABLE II

DESIGNED PRESSURE DROPS AND VELOCITIES FOR EDGAR STATION 1400-LB. UNITS

Steam flow, lb. per hr........	125,000	150,000	175,000	200,000	225,000
Superheater drop, lb. per sq. in.	13	18	25	32	40
Reheater drop, lb. per sq. in...	1.0	1.4	1.9	2.4	3.0
Steam velocity in superheater tubes, ft. per sec..........	13.5	16.2	18.9	21.6	24.3
Steam velocity in reheater tubes, ft. per sec...........	12.6	15.1	17.6	20.1	22.6

Feed Pumps

The boiler feed pressure cycle for normal operation is broken at 500 lb., motor driven primary pumping units in duplicate raising the pressure to this point where water is either fed to the older boilers or to the secondary pumping units (also in duplicate) which discharge at 1600 lb. The primary units take their suction from the deaerator at approximately 260 deg. fahr. A steam driven emergency 1600-lb. pump is installed which is designed to take water at low heads and at temperatures up to 260 deg. fahr.

Various types of packing have been tried with inconsistent results, the same type of packing giving both long and short life under identical operating conditions. High water temperatures have caused packing failure after satisfactory operation at a lower temperature. The pumps have been packed about every two weeks when repaired for other reasons. The casings have shown but one leak which was repaired by peening.

The hydraulic balancing disks have given considerable trouble due to rapid wear. The original ball thrust bearings have been replaced with Kingsbury thrust bearings. The pumps are now balanced by hydraulic balancing drums in place of the balancing disks.

The proposed design of the completed station is such that a loss of one of the two pumps now installed, which would then be supplying eight higher-pressure boilers, will be permitted without a reduction of boiler capacity, if the emergency steam pump is used.

The driving motors and turbine have given practically no trouble. The 3600 r.p.m. motor in the initial installation threw oil and recently had to be repaired because of a ground in the slip ring leads.

Because of the frequent opening of the 1600-lb. pumps, no regular routine internal inspections have been made. Parts have been renewed frequently in these pumps. The impellers have shown no undue wear.

The new higher pressure pumps have not yet been tested. The original high-pressure pump was low on discharge pressure and efficiency, but the newer pumps have apparently maintained their original discharge pressures and capacities.

Turbines

Since the start of commercial operation, the 10,000 kw. high-pressure turbine has run in perfect balance, giving no vibration trouble, and has suffered no loss of capacity. The original high-pressure turbine has increased its water rate 20 per cent and reduced its capacity accordingly. The new high-pressure machine has been satisfactory from the standpoint of governor performance, thrust bearing service, and performance of both interstage and external packings. Although the steam by-pass with the new turbine is designed for manual and steam pressure controlled operation, it is arranged to function automatically when the turbine trips out until the third high-pressure turbine and other boilers are installed. Normally the reheat is manually controlled by a damper in the reheater setting that varies the gas flow through the reheater. A desuperheater is also provided to reduce the temperature of the steam entering the reheater when the turbine by-pass is in use or the turbine is carrying low loads. Because of pump troubles the high-pressure turbine exhaust extraction heater has been used very little; hence, no report can be made on its performance.

The longest continuous run of the new high-pressure turbine to date (Feb. 9, 1929), is 172 hr. Although the turbine could have been run almost indefinitely, a longer run was not made because of low steam load on the station.

The 10,000 kw. turbine has not been opened for internal inspection since the start of commercial operation. After a few hours of preliminary operation, one bucket was missing from the 16th wheel and another cracked. The 13th, 14th, 15th and 16th wheels were rebuilt with buckets of a heavier design. A conventional type of steam strainer is used. The turbine shaft has shown no undue deflection. The machine is not multivalved for partial load economy.

The original higher pressure turbine has shown considerable corrosion of lower stage buckets, but no erosion. Considerable "carry-over" from the boiler has been deposited on the blades and nozzles of this machine, which may account for the increased water rate mentioned above.

Design Features

Boiler

The boiler tubes are in two banks, with the superheater between them and the reheater above the top bank. The lower bank tubes are 3¼ in. O.D., 11/32 in. thick, hot finished seamless steel. The two lower rows of this bank form a slag screen and are spaced vertically above each other 12 in. on center. The upper row is spaced 12 in. below the lowest row of the six upper rows of the lower bank. These six upper rows are staggered and spaced 8¼ in. on centers. The tubes in the upper bank are 2 in. O.D., No. 4 B.W.G. hot finished seamless steel.

The boiler drum is 38 ft. 4 in. long, 48 in. I.D., 4⅝ in. thick, of forged steel with heads forged integral with the shell.

The superheater consists of four approximately concentric loops, the ends connected into the upper and lower headers and is arranged for three steam passes. The tubes in the first and second passes are 2 in. O. D., No. 4 B.W.G., "Enduro A," the latter being a heat resisting alloy containing about 17 per cent of chromium. The superheater is designed for a pressure drop of 32 lb. from the boiler drum to the superheater outlet at 200,000 lb. per hr.

In the furnace, the side and rear walls are water cooled (Bailey type) and contain altogether 1235 sq. ft. of surface.

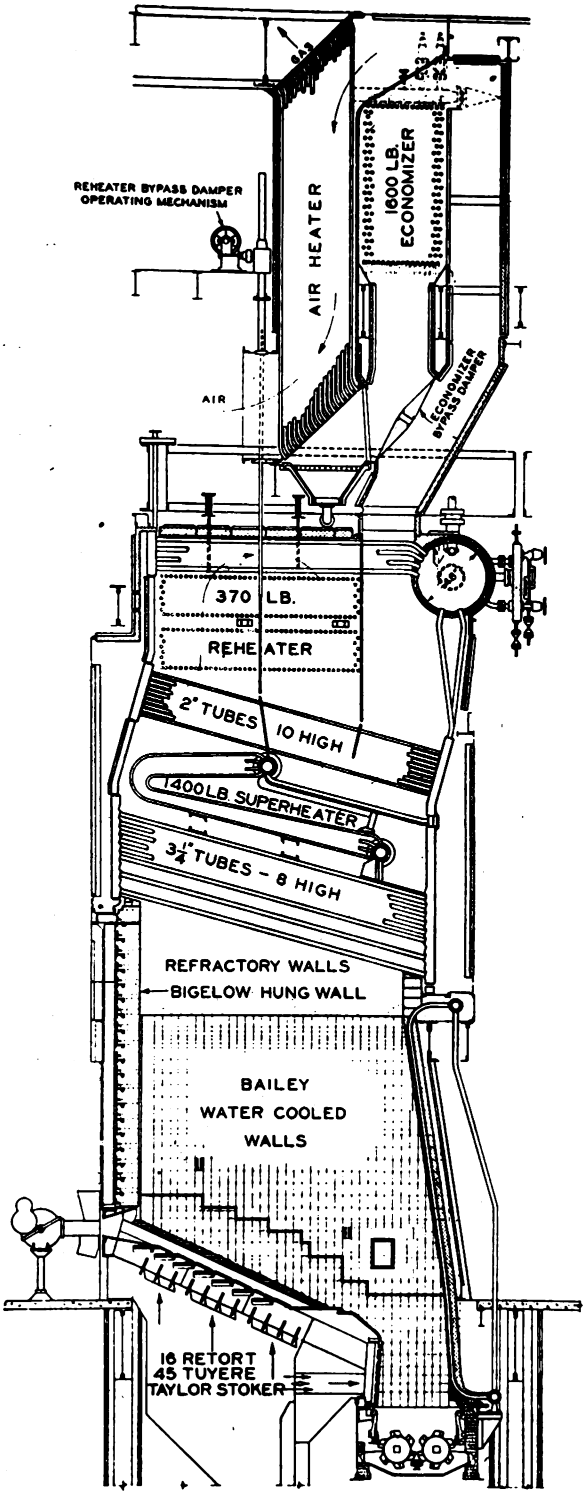

FIG. 11—Cross Section of 15,093-Sq. Ft., 1400-Lb. Boiler, Edgar Station Expansion.

The fuel burned is ordinary run-of-mine New River bituminous.

Turbine

The reheated steam discharges into the common 360-lb. per sq. in. header for the lower-pressure turbines. This arrangement is used for flexibility.

A drop of approximately 10 lb. is expected between the exhaust of the higher-pressure turbine and the throttle of the lower-pressure turbines.

On the lower-pressure machines an improvement of approximately 750 B.t.u. per kw-hr. gross is experienced with extraction operation over non-extraction. The effect of the extraction heater taking steam from the higher-pressure turbine exhaust is to increase the ratio of high pressure turbine output to lower-pressure turbine output with the same heat input to the boilers and consequently to better the station economy. The final temperature by extraction from the lower-pressure turbine is approximately 300 deg. fahr. at full load. A temperature of 420 deg. fahr. is expected with the high pressure turbine exhaust extraction heater in operation. With the exception of the deaerator, which is an open heater, the heaters are all of the closed surface type. No special material was used in the tubes of any of the heaters.

Piping

A flexible arrangement of headers is used, there being a 1300-lb. header, an exhaust reheater header, and a 360-lb. header to supply the lower pressure turbines.

All piping is designed for a flow of approximately 250,000 lb. of steam per hr. per boiler. Velocities of approximately 7500 ft. per min. are reached in the 1400-lb boiler leads and 10,000 ft. per min. in the leads to and from the reheater.

Sargol joints are used for high pressure steam and water piping.

Fig. 11 shows a cross section of the new 1400-lb boiler at Edgar Station.

Statement by the Union Gas & Electric Co., Cincinnati, Ohio

Operating Experiences at Columbia Power Station

Boilers

During the interval between the time the boilers first went into service and January, 1929, the boiler load factors have been as follows:

	Per Cent
Reheat boilers........	54.3
Standard boilers......	41.6 based on maximum boiler output
Standard boilers......	50.1 based on normal rate of operating

The limiting factor of these values has been the system night load. In the case of the standard boilers, the spare boiler capacity has resulted in a value lower than that of the reheat boilers.

With the feed water treatment used it is possible to keep the boilers on the line indefinitely. Make-up water equivalent to 2 per cent of the total steam generated is treated and fed into the system. A cold intermittent softener using lime, ferrous sulphate, and soda ash is used in the treatment of raw Ohio River water. This results in a water of no more than 17 p.p.m. hardness, and 170 p.p.m. total solids. In addition, a value of 50 p.p.m. of sodium phosphate is maintained in the boiler water. By limiting the total boiler water concentration to 1000 p.p.m. by blowdown, satisfactory operating is obtained. No scale is formed and no foaming or priming occurs.

No difficulty has been encountered in maintaining the correct water level in the boiler drums during extreme and rapid changes of the plant load.

It has been difficult to collect data for obtaining the per cent moisture in the steam leaving the boiler drums. Values ranging from 0 to a maximum of 0.3 have been obtained. It has been found that at boiler water concentrations as held in this station, water level and rating have no measurable effect in changing the moisture content of the steam leaving the drums.

Difficulty in maintaining tight joints between the economizer hand-hole caps and headers has been corrected by using 1/16 in. asbestos sheet gaskets on these joints. At the present time, some leakage is developing at the rolled joints of some of the economizer tubes which is causing corrosion at the tube ends. Rerolling the tubes and eliminating tube expansion strains should correct this leakage.

The longest continuous turbine run has been for 54 days, while rebuilding the second turbine from a 45,000 kw. tandem compound unit to a cross compound unit of 63,000 kw. capacity. During this same period, the reheat boiler for the turbine operating had a continuous run of 26 days. It was taken off the line due to an economizer tube leak.

Boiler Maintenance

Since initial plant operation in January, 1926, five boiler tubes have been replaced. Three of the failures were due to steam cutting from a leak in a superheater tube. Tube replacements in the 600-lb. boilers have not been greater than in 250-lb. boilers. While it takes more time to roll a tube in a 600-lb. boiler, the total time for replacing a tube is practically the same as the time required for replacing a tube in a 250-lb boiler, due to the factors of accessibility and smaller diameter tubes.

The operating experience to date has indicated that the tube material for economizers, boilers, and superheaters has been satisfactory.

The boiler and superheater safety valves have given entire satisfaction. Since the plant has started operation, the station load has suddenly dropped sufficiently on three different occasions to make all the safety valves operate. After each operation, the valves seated properly without leakage.

Feed Pumps

Motor driven boiler feed pumps are installed for normal operation and two steam driven pumps are installed for reserve. The station was designed for the operation of the motor driven pumps. These are single cylinder, six stage pumps operating against a head of 750 lb.

The pump thrust bearings have been satisfactory. The pumps are hydraulically balanced and proper pump operation is checked by a pressure gage installed in the leak-off of the pump discharge end-balancing chamber. If the pressure in this chamber indicates values above normal due to interstage leakage, the pump is unbalanced and it is taken out of service for inspection and repair. The pressure gage reading is an indication of the thrust action of the pump and serves as a safeguard for the bearing.

Each unit has three motor driven pumps, two operating and one reserve. Sufficient pumping capacity therefore is available in case of a pump outage which does not result in a drop of boiler output.

Driving motors and turbines have been entirely satisfactory.

Pump Maintenance

The boiler feed pumps are inspected annually. At this time new packing is installed in the glands. The stage impellers have shown no wear or erosion, and with the exception of packing gland sleeves no parts required renewals.

Turbines

Due to a salt deposit forming on the blades and nozzles of the high-pressure turbines, a loss of capacity of approximately 1200 kw. per week has been experienced. Improved sealing of the boiler drum steam circulating baffles and reducing the maximum total boiler water concentrations have improved this condition very much.

The turbines have operated without vibration, and good performance has been had from operating governors, thrust bearings and packings.

The steam is reheated between the high- and low-pressure cylinders in a separate reheat boiler. No difficulty has been encountered with excessive or insufficient reheat with light loads on the turbine since the rate of firing the reheat boiler is regulated to give the proper reheat temperature. The rate of change of reheat temperature is slow due to the large number of reheater tubes and large steam space, and it is, therefore, possible to obtain very uniform reheat temperatures.

Extraction heater performance has been satisfactory, and results obtained are meeting the guaranteed values.

Turbine Maintenance

Turbine inspections have indicated that no undue erosion is had on turbine blades due to the higher steam density. A number of stages in the exhaust end of the low-pressure turbines were originally bladed with thin-edged blades. Cracks developed in these blades, and they were replaced with ones of greater cross-sectional area and redesigned dovetails.

The blades have been free from the battering action of foreign material passing through the turbines. Two screen strainers are used, one in front of the control valves and the other around the first stage bowl. The screen strainers are made of No. 14 gage wire and are 7 mesh.

STATEMENT BY THE SUPER-POWER CO., PEKIN, ILL.

Powerton Power Plant

The first section of this new 650-lb. plant, a description of which will be found in the 1927-28 Report of the Subcommittee on Pulverized Fuel (N. E. L. A. Publication No. 278-85), went into service in the latter part of 1928.

A duplicate of the above installation, consisting briefly of a 55,000-kw. General Electric turbine and three pulverized coal fired Babcock & Wilcox boilers, one of which is a reheat boiler, has been ordered.

As the equipment has already been described and has just gone into service, no official statement or operating data were obtained.

STATEMENT BY THE STATE LINE GENERATING CO., STATE LINE, IND.

State Line Power Station

The above 600-lb. station is now under construction, the first section consisting briefly of a 208,000-kw. General Electric turbine-generator unit, made up of one 76,000-kw. high-pressure unit and two 66,000-kw. units, so connected that the units can be operated independently if desirable.

A steam reheater will be used between the high-pressure and the low-pressure units.

The boilers are Babcock & Wilcox cross drum, single pass type with the convection superheater set above the boiler tubes.

The furnace is water-cooled by Bailey wall construction and fired by eight Calumet type burners receiving coal from two No. 70 Lehigh pulverizing mills.

A B. & W. steaming economizer and a B. & W. vertical tubular type air heater completes the main part of the unit.

No official statement was obtainable from the operating company.

STATEMENT BY THE ELECTRIC MANAGEMENT & ENGINEERING CORP.

There is being built for the Jersey Central Power & Light Co. at South Amboy, N. J., on the Raritan River, a plant equipped with three 1400-lb. boilers and two turbine units for operation at a throttle pressure of 1250 lb. It is expected that this plant will go into operation in March, 1930.

The principal items of equipment to be installed in this plant are:

2—25,000-kw. G. E. steeple compound turbine generator units, each unit consisting of—
    1—5100 kw., 80 per cent power factor, 3600 r.p.m. high-pressure element, and
    1—19,900 kw., 1800 r.p.m. low-pressure element.

The low-pressure element drives the exciter for both the high-pressure and low-pressure elements. The low-pressure element of each unit is served by

1—20,500-sq. ft. Foster Wheeler, single pass surface condenser.

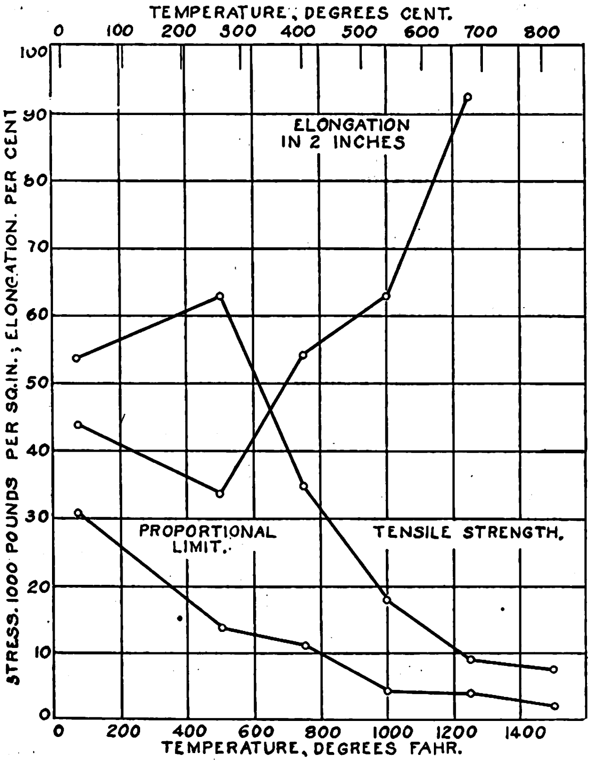

FIG. 12—Properties of 0.13 Carbon Steel at Elevated Temperatures as Determined by Short Time Tensile Tests.

The boiler plant will consist of:

3—Babcock & Wilcox boilers arranged for an output of 250,000 lb. of steam each, with a total temperature of 750 deg. fahr. and a maximum pressure of 1400 lb. The normal gage pressure will be about 1310 lb.

Each boiler is equipped with both a gas and a live steam reheater. The heating surfaces are as follows:

	Sq. Ft.
Boiler	7,250
Primary superheater	5,900
Desuperheater	225
Gas reheater	12,900
Steam reheater	2,190
Water walls	2,036
Economizer	4,420
Air heater	32,052

A notable feature in the boiler equipment is a provision for keeping constant initial and constant reheat temperatures. The boilers will be fired with pulverized fuel and equipped with Bailey water walls with slag tapping furnace. The unit system of firing will be installed.

The turbines will be bled at five points, and at the best point the turbine room heat rate is estimated to be from 9280 B.t.u. to 9290 B.t.u. The heat balance calculations have not as yet been completely worked out.

Properties of Metals at Elevated Temperatures

Statement by A. E. White and C. L. Clarke, University of Michigan

The increasing use of metals at temperatures and pressures that were unthought of a few years ago necessitates an understanding of the physical properties of the metals when at elevated temperatures. Even though many investigators have undertaken studies concerning the high-temperature behavior of metals, the field as a whole, due to its vastness, is hardly yet scratched.

Metals used at elevated temperatures may be divided, roughly, into ferrous and non-ferrous groups. The main divisions under the ferrous group are the plain carbon steels and alloy steels, while subdivisions of the non-ferrous group would be non-ferrous metals and non-ferrous alloys. Although both non-ferrous metals and non-ferrous alloys have applications in high-temperature work, their use is rather limited, due to their cost.

Results obtained from both the short-time tensile and long-time creep tests show the limitations of plain carbon steel, especially at temperatures much above 750 deg. fahr. Short-time tensile tests conducted on a 0.13-per cent carbon steel, Fig. 12, show the tensile strength of the steel to fall off rapidly at temperatures above 500 deg. fahr., while the same is true of the proportional limit at temperatures above 750 deg. fahr.

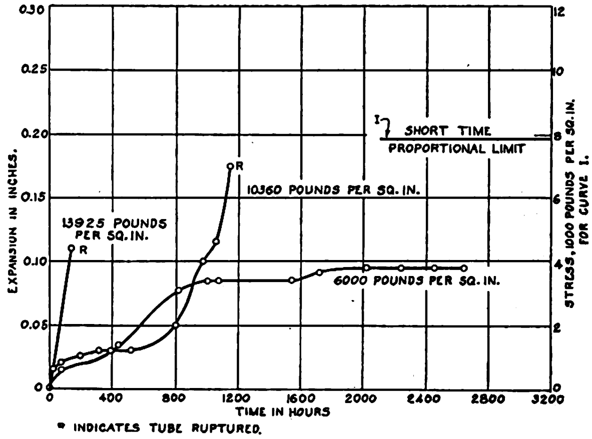

FIG. 13—Expansion Test on 0.38 Carbon Steel at 1000 Deg. Fahr. (538 Deg. Cent.).

Results obtained from expansion tests on a 0.38-per cent carbon steel, Fig. 13, show a stress of 6000 lb. to produce marked deformation over a period of 2500 hr. From these and similar tests, White and Clarke computed the stress to produce rupture of this steel at 1000 deg. fahr. in a period of 100,000 hr. as being 5600 lb. For 0.13 per cent carbon

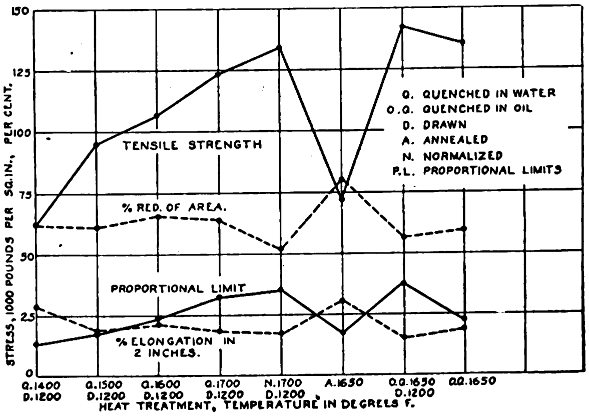

FIG. 14—Effect of Heat Treatment on the Tensile Properties of 0.60 Per Cent C, 1.43 Per Cent Cr., 2.19 Per Cent W Steel at 1000 Deg. Fahr.

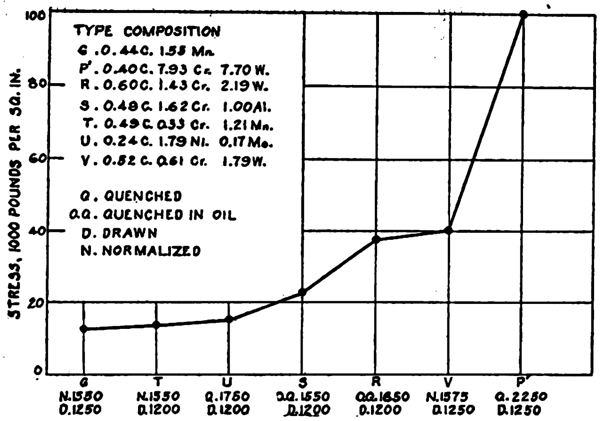

FIG. 15—Maximum Proportional Limit Values Obtained at 1000 Deg. Fahr. (538 Deg. Cent.) with Various Selected Steels.

steel under the same conditions, the necessary stress was found to be 5200 lb. per sq. in.

Since it appears necessary to resort to alloy steels for high-temperature duty, the question is raised as to which of these are the most suitable. Here again the alloying additions must be kept as low as possible, or else the cost becomes prohibitive.

In the author's opinion, the chromium-tungsten steels, to which attention was first directed by Mr. Malcolm, are believed to be among those best suited for high-temperature duty. If the temperatures to be employed are not above 1000 deg. fahr., the steels of this class containing relatively low percentages of these two elements will, if properly heat treated, give satisfactory load-carrying ability.

Short-time proportional-limit values obtained with this steel at 1000 deg. fahr., after various heat treatments, Fig. 14, vary from 17,500 to 40,000 lb. per sq. in. Fig. 15 also shows the chromium-tungsten steels to exhibit the highest proportional-limit values at 1000 deg. fahr. of any of the steels considered.

The results of creep tests conducted upon a steel of this type, Fig. 16, show this steel capable of withstanding relatively large stresses for long periods of time.

Higher Pressures and Temperatures

Statement by C. F. Hirshfeld, The Detroit Edison Co.

In America we have gone about the increase of steam pressure in a perfectly characteristic way. We have assumed that we wanted to take as few steps as possible into the unknown or the untried. Therefore, we have advanced rather slowly, first confining ourselves to pressures which did not involve reheating. Then we advanced to about 600 lb., the lowest pressure which appeared to justify the additional expense of reheating equipment, and finally we advanced to the 1400-lb. region, at which we appear to have halted for the time being. In all cases we have found only slight modifications of existing boiler types to be necessary.

In all of this advance we have been more or less unconsciously guided by the maximum steam temperature that we believe it safe to use, namely a value between 700 and 750 deg. fahr. A very brief study of steam charts will show that the thermal advantage of increasing the initial steam pressure is definitely tied to the assumed maximum steam temperature. At any given assumed initial steam temperature, either with or without reheat, increasing the steam pressure from a low value causes a thermal saving, but the rate of increase of this saving decreases as the pressure rises, until there is finally reached a pressure beyond which improvement is insignificantly small. This point moves up to higher pressures as the assumed initial temperature is increased. We have temporarily halted at about that pressure which corresponds to an optimum value with our presently assumed upper limit of temperature.

Were we now to assume it possible to operate with steam temperatures of the order of, say, 900 deg. fahr., we should obtain new values for the pressures giving optimum results with and without reheating. If we assume as possible 1000 deg. fahr. we should obtain a new set of values, and so on.

In continental Europe the move toward higher pressures has been made along different, but equally characteristic, lines. There the engineers endeavored to analyze in advance all the new factors which might be expected to enter the problem, and to then produce designs which would properly take account of these new factors. They anticipated certain difficulties as the result of such analyses. Briefly, the principal considerations were as follows:

1. As the pressure rises the saturation temperature also rises and, therefore, the temperature of heat trans-

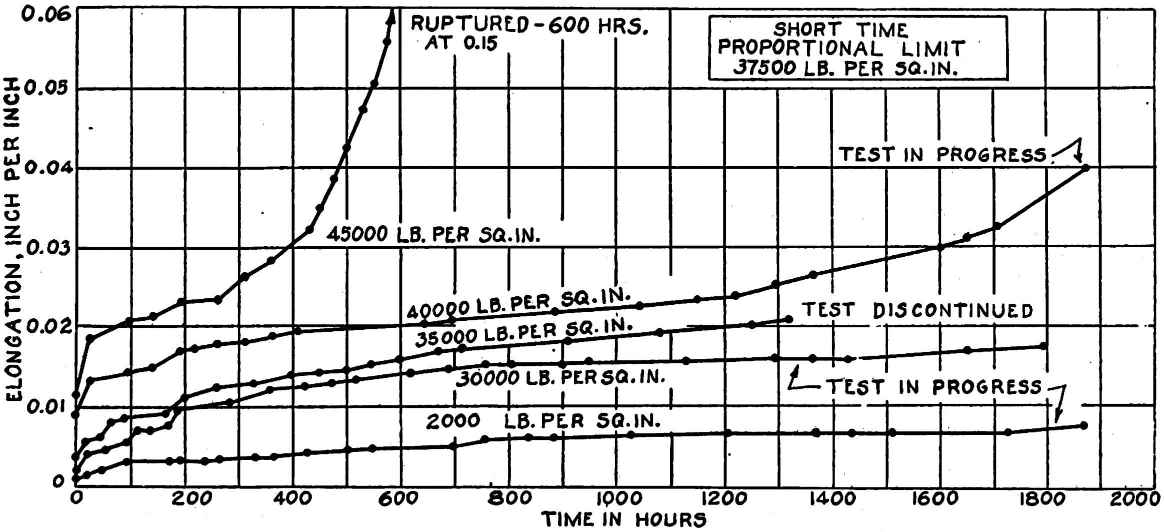

FIG. 16—Flow Tests on 0.6 Per Cent C., 1.43 Per Cent Cr., 2.19 W Steel at 1000 Deg. Fahr. (538 Deg. Cent.).

ferring metal in the boiler also rises. This leads one to anticipate more difficulty in preventing burning of such surfaces, particularly in boilers operating at high rates of output.

2. With the metal thus endangered, a very thin film of scale may be expected to threaten the life of the tube to the same degree as much thicker scale at lower temperatures.
3. As the pressure rises, the specific volume of saturated steam decreases rapidly, and the difference of density of steam and water in the boiler decreases. This threatens the circulation in boilers of the ordinary type in which density differences in different parts cause the "natural" circulation on which we depend.
4. The latent heat of vaporization also decreases as the pressure rises, so that the anticipated decreased rate of circulation is accompanied by a phenomenon which tends to make each pound of water flowing over the heating surface less effective as a heat remover.
5. The chemistry of boiler waters at high pressures and temperatures is practically unknown, so that many unsuspected opportunities for trouble may be hidden in high-pressure boilers of the ordinary type.
6. Finally, the cost of boiler drums of conventional design must increase rapidly unless the diameter is rapidly decreased as the pressure increases. This brings in new problems, both with respect to steam freeing surface and with respect to the thermal storage required to minimize pressure changes during sudden changes of demand for steam.

Some few European designers and builders have gone ahead as we have with more or less conventional types. Others have contemplated this long list of factors of unknown weight and have thought it necessary to design something new. That which they have designed has depended somewhat upon the weight which they respectively assigned to the different factors of doubtful significance.

Thus the inventor of the Atmos Boiler anticipated difficulties in heat transfer between metal and water, difficulties from the small volume of high-pressure steam and difficulties from cost of equipment depending upon the conventional method of heat transfer. So he adopted a rotating boiler tube with provision for most intimate forced contact between water and metal. He also obtained plenty of surface through which the steam might separate itself from the water, and an artificial separation through centrifugal effect as well.

The inventor of the Benson Boiler attempted a unique and striking solution. He made his boiler proper nothing but a water heater without drums or steam space. Just what properties this construction will ultimately be discovered to possess is not yet known. The results on large scale experimental plant lead the present backers of the system to believe it very promising and a direct competitor of comparatively low pressure, say 400 or 500 lb.

The inventor of the Schmidt process adopted a radically different solution. His high-pressure boiler consists of two boilers operating at different pressures. The boiler operating at the higher pressure is filled with distilled water, which never leaves it except through unavoidable leakage. This water is converted into steam and is then condensed in coils immersed in water contained in the lower pressure boiler, the condensate running back automatically to the boiler in which it was made. The distilled water then serves merely as a heat transferring device and protects the surfaces exposed to the fire from the effects of scale deposition. This immunity is purchased at a considerable difference between the pressure at which the steam is made in the high-pressure boiler, and the pressure at which steam is made available for use in the low-pressure boiler.

Since the higher pressure boiler evaporates only distilled water which travels around in a closed circuit, the tubes of which it is composed may be given very small diameter, as it is not expected that they will ever have to be turbined. Also, it makes no difference if this boiler delivers wet steam and drums are not necessary to obtain freeing surface. All parts may, therefore, be made of small diameter and hence low cost.

The lower pressure boiler may consist of a simple, cylindrical shell, big enough to contain the desired quantity of water and the heat transfer coils. It can be so constructed that few or no openings are made in the cylindrical wall and, therefore, it can be made comparatively cheaply, particularly in the case of comparatively long drums.

A locomotive embodying this principal has been constructed for use on the government-owned railroads of Germany and is reported to be giving remarkable thermal economy in comparison with the older types and "without any great increase of first cost."

Loeffler system is still different. In this, steam which has been highly superheated is blown into water in a simple drum and generates saturated steam from that water at the desired pressure. This saturated steam is passed through a separately fired superheater equipped with air preheater and economizer to obtain high efficiency of the combustion part of the cycle and with a regenerator to obtain high efficiency of the prime mover. Part of the steam which is superheated goes to the prime mover, and the remainder is returned to the water-containing drum to keep up the production of saturated steam. It is obvious that steam made in this drum could not be made to flow through the superheater and then return to the drum because of the pressure drop which it would experience. A steam pump of some sort is, therefore, necessary. This pump is inserted in the saturated steam line. It receives the steam made in the drum and pumps it through the superheater.

The characteristics of this system are peculiar. At low steam pressures the required pumping work would be so great as to make the method worse than unprofitable. But, as the pressure rises, the pumping work rapidly becomes a much smaller percentage of the work that can be obtained from the useful steam made. At pressures above about 1500 lb., the system appears to acquire real commercial promise, but the inventor prefers a pressure of about 1800 lb. or higher.

It is self-evident that the heat of superheat is all that is effectively transferred from fire to generated steam. Therefore, a superheater of large size is required, and a high superheat temperature must be used if financial economy is expected. The inventor uses a steam temperature of about 900 deg. fahr. and claims to have had "complete success" with large size experimental equipment.

One familiar with our practice will immediately question the use of 900 deg. fahr., particularly when told that Dr. Loeffler uses the same metal that we use at 750 deg. fahr. temperature. The answer lies merely in a different evaluation of the necessary factors of safety. By this is meant both the factor of safety with regard to unit fiber stress in the metal at normal working temperature and the factor of safety with respect to abnormal operating conditions. It is self-evident that comparatively large economies could be made with present American plant design if we were willing to adopt such temperatures.

Some may feel that a superheater can be built to operate satisfactorily when delivering steam at 900 deg. fahr., but that the prime mover might be expected to give trouble. The Loeffler system presents a ready answer to such, since the steam intended for use in the prime mover could, if desired, be tapped off at an intermediate point in the superheating equipment.

Numerous other evolutionary and revolutionary suggestions and designs have been produced, but those mentioned above appear to have had the most serious practical consideration in Europe. They do not appear to have been given sufficient study in this country, as yet, to enable us to determine what, if any, commercial value they may have under our conditions. If, after such study has been given them, it should develop that they are not promising for use in central power stations, or are definitely not adapatable to such use, it may be discovered that they do open up very desirable possibilities in industrial plants of various sorts. Some of them certainly disclose promising opportunities for very flexible arrangements in connection with old plants, process steam requirements and other considerations of particular interest to many plants of these sorts.

It is thus too early to evaluate these products of a different method of attack. It is not, however, too early to study them in the light of our requirements and to see whether they hold anything of promise or portent to us.

The Relation of Embrittlement to Higher Steam Pressures and Temperatures[1]

STATEMENT BY FREDERICK G. STRAUB, ENGINEERING EXPERIMENT STATION, UNIVERSITY OF ILLINOIS, URBANA, ILL.

Recent data collected from power plants which have experienced embrittlement indicate that the subject of boiler feed water for higher pressure boilers must receive more attention. During the last year extensive cracking has been detected in two plants, operating at 380 and 450-lb. steam pressure. Much cracking has also been found at lower pressures, but these two instances serve to illustrate what will take place at the higher pressures.

One of these plants used a natural sodium carbonate well water low in sulphate content, while the other used a surface water which, when internally treated, resulted in too low a sulphate alkalinity ratio.

Neither of these plants was adhering to the ratio of sulphate to alkalinity as recommended by the A. S. M. E. for 250-lb. pressure. Both plants were having regular analyses made of the boiler waters which showed the ratios to be low.

The higher pressure plant had the boilers crack after two years' operation, while the other operated about three years.

Since investigating these interesting cases of embrittlement, the writer has had occasion to inspect the analyses of a large number of waters from boilers operating at pressures over 400 lb. These analyses indicate that a great many of these plants have not been maintaining the sulphate to alkalinity ratio recommended for 250-lb. pressure. The question is often asked whether the ratio for 250 lb. is protective at higher pressures. It is felt that at higher pressures this ratio should be changed so as to have higher sulphate to alkalinity ratios. The research conducted by the writer has shown that at 500-lb. pressure, a ratio of 2.8 was not protective, while a ratio of 3.6 was. These results were obtained from accelerated laboratory tests and should be considered as minimum protective values. In operating plants, the ratios should be held at values greater than this.

The laboratory tests, in addition to giving the ratio which might be used, also show that, unless the entire desired ratio is maintained, there is no protection. Thus, if spasmodic attempts are made to maintain the desired ratios and only ½ or ⅔ of the desired sulphate is maintained, the boiler is no better protected than if no sulphate were present. Thus ½ of the ratio is no better than none.

It would be well at pressures above 250 lb. to carry the ratio over 3. At pressures around 600 lb., this ratio should be at least 7. This should be a minimum value to be maintained at all times.

Experimental laboratory work has shown that soluble phosphates are effective in preventing embrittlement. The use of phosphate depends upon the ability to maintain sufficient soluble phosphate in the boiler water at all times. Data are being collected from power plants using phosphate for this purpose. These plants are not attempting to maintain the sulphate ratio. Until more definite plant data are available, it would be well to proceed rather slowly in the use of phosphate to prevent embrittlement.

When higher boiler pressures such as 1300 lb. are reached, the danger of embrittlement is eliminated to a large extent through the absence of riveted joints. Certain highly stressed areas such as where the tubes are rolled into the drums might be subject to this trouble. If the joints between the tube and drum are made so as to be tight from the inside and properly vented at the outside, the potential danger should be reduced to a large extent. Practically all boilers operating at these pressures are using evaporated make-up, and if condensers are kept tight they should be able to operate with an extremely low alkalinity, which would also be of material help in eliminating the possibility of embrittlement.

STATEMENTS BY POWER COMPANIES IN REFERENCE TO RELATIVE CONSTRUCTION COSTS OF PLANT UNITS DESIGNED FOR 1200 AND 400 POUND STEAM PRESSURE

A number of statements have been contributed by power companies, and these are published as a part of this report for the purpose of indicating the difference in cost of construction for plants of 1200 and 400-lb. steam pressure. These statements fall into two groups, one giving costs from plants which are actually built and the other from estimates made for plants which were contemplated.

Since it is difficult to reduce the various studies to an identical basis of comparison, the figures do not lend themselves well to a general summary. Involved with the costs in the ordinary case, there are differences due not only to steam pressure, but also to difficulties of construction and to features of design made to fit local requirements and policy.

A net figure has been reached in each of the statements for the difference in cost due to pressure as a result either of actual experience or of comparable estimates. It is to be noted that the various net figures reported for plants actually built do not fall far apart.

The several statements follow:

STATEMENT BY THE MILWAUKEE ELECTRIC RAILWAY & LIGHT CO., MILWAUKEE, WIS.

High-Pressure Versus Low-Pressure Plant Costs

The greater cost for 1300 lb.-300 lb. over all 300-lb. pressure installation was found to be $204,410 on the basis of an addition of 39,100-kw. capacity to an existing station. This represents $5.28 per kw.

Greater costs for boiler plant equipment and electric plant equipment were found to be $235,523, and credits of $28,113 were taken for tunnel and circulating water system and for coal handling system. The 1200-lb. turbine is non-condensing, and an equivalent tunnel capacity is available for future 300-lb. condensing turbines. A credit is taken for coal handling and preparation equipment made available for future installations because of greater thermal efficiency of the 1200-lb. equipment.

Of the greater cost for boiler plant equipment and electrical plant equipment, 51.5 per cent is due to boiler alone, 11.8 per cent to increased superheater and reheater costs, 16.3 per cent to increased piping costs, 8.6 per cent to increased boiler feed pump costs, 7.6 per cent to increased electrical plant costs, and the balance of 4.2 per cent is due to engineering, tools, meters and instruments, safety valves, trap system, etc.

High-pressure installation costs are those of an initial installation, but 300-lb. pressure costs are based upon considerable experience. In the latter case advantage was taken of all improvements available to reduce costs; yet in the high-pressure costs appear figures later found unnecessarily high. The above difference of $5.28 per kw., therefore, should be maximum.

---

[1] This article is an elaboration of part of the material that has appeared in Bulletins 155 and 177 of the Engineering Experiment Station of the University of Illinois. The publication of this article has been authorized by Dean M. S. Ketchum, Director of Engineering Experiment Station.

Present design of a second high-pressure installation indicates that this margin will decrease.

STATEMENT BY STEVENS & WOOD, NEW YORK, N. Y.

Table III shows the relative unit costs of the 400-lb. pressure station at Toronto, Ohio, and the 1400-lb. pressure station at Deepwater, N. J.

TABLE III

RELATIVE COSTS OF 400-LB. AND 1400-LB. INSTALLATIONS—STEVENS & WOOD

	Cost—Dollars per Kw.	
	Toronto 140,000 kw. 400 lb. Pressure	Deepwater 159,000 kw. 1400 lb. Pressure
Land	$0.82	$1.57
Preparation of Site	1.64	0.21
Yard work	4.42	4.48
River front work	......	2.68
Foundations	15.93	4.16
Building	10.78	10.11
Piping (not including circulating water)	4.75	5.09
Boiler room equipment	23.41	31.01
Turbine room equipment	26.47	21.34
Electrical switching equipment (in station)	12.11	8.98
Service equipment	2.43	5.37
Coal handling	4.67	3.19
Step-up substation	6.68	6.62
Preliminary operation	0.74	0.50
Total	$113.85	$105.31

The costs shown for the Toronto Station are the practically final actual costs for a balanced plant having four 35,000-kw. turbine (the nameplate rating of these units is 30,000 kw., but they have demonstrated in actual service that 35,000 kw. can be carried continuously in summertime within safe temperature limits). These costs include all known expenses in connection with the station up to and including engineering and engineering fee, but do not include interest during construction nor any other corporate expenses of the owning company.

The Deepwater costs here shown are from estimates only. However, over half the total cost has been incurred, and a careful survey of the situation indicates the project can be completed within the figures shown. These figures include the same complete costs as mentioned above for Toronto.

The actual project at Deepwater consists initially of the installation of two main power units with their boilers, each compound unit having a nameplate rating of 53,000 kw. Building space and boilers for a third such unit are also provided, but in place of a third main power unit, there is installed a high-pressure turbine element only which, with several evaporators, supplies a large amount of industrial service steam. It has, therefore, been necessary to adjust the estimate covering the actual project to make it applicable to three complete power units or 159,000 kw. of nameplate rating. (It is anticipated these units will safely carry at least 55,000 kw. continuously and quite likely 58,000 kw. However, the figures given above are based on the nameplate rating.)

Referring now to the individual groups in the above table, that of land needs no comment, being independent of pressure and governed by the locality and acreage purchased.

Toronto is high in preparation of site on account of having to move a highway formerly across the site as well as an interurban traction railway.

Toronto is directly on the Ohio River front, and the condensing water intake structures are a part of the building substructure, their costs coming under foundations: whereas at Deepwater the building is set back some 200 ft. from the edge of the Delaware River, and certain water-front structures are separated from the building proper.

Referring to the item of foundations, Toronto not only had a greater plan area per kw., but a river rise of over 40 ft. had to be provided for, so that the Toronto foundation structure is a relatively costly one as compared with the simple pile and concrete mat foundation at Deepwater.

The following summary comparison gives some information on the relative foundation and building costs:

	Sq. ft. per kw. Plan Area	Cu. ft. per kw. Building Volume above Basement Floor
Toronto	0.49	63
Deepwater	0.40	40

In regard to piping, presumably the true relative cost between 400-lb. and 1400-lb. pressure stations is greater than here shown for the latter. In both stations, the piping is relatively simple, but in Toronto, it covers four units and eight boilers, while in Deepwater it covers three units and six boilers only.

Presumably, the difference shown in boiler room equipment is fairly correct for the different pressures.

This is probably also true for the item of turbine room equipment where, with the larger compound units at the higher pressure, part of the unit has a speed of 3600 r.p.m. These comparative costs are also affected by the relatively smaller condensing equipment required on account of the better water rates on the high-pressure units.

Referring to electrical switching equipment, these costs, of course, vary with the type and complexity of the auxiliary equipment selected and are not in any way affected by the difference in pressures.

Similarly, the remaining groups of costs shown are not affected by pressure, except possibly in coal handling, where the quantity of coal per kw. is slightly less at the higher pressure.

Unfortunately for comparative purposes, the true total relative unit costs for the two pressures are overshadowed in these figures by the greater differences caused by size of units, foundation conditions and type of auxiliary equipment, but these figures and other studies lead us to the belief that a 1400-lb. pressure plant should cost, not to exceed, 5 per cent more than a 400-lb. pressure plant.

STATEMENT BY W. S. BARSTOW & CO., READING, PA.

In considering the relative construction cost of 400-lb. vs. 1200-lb. plants, it is believed that for stations having approximately 50,000-kw. units or larger, a plant designed for 1200 lb. will cost $6 more than a plant designed for 400 lb. This figure is based on experience in designing and constructing several 400-lb. stations during the past few years and upon studies in connection with the Holland Station when 400, 600 and 1200 lb. were considered.

STATEMENT BY STONE & WEBSTER, INC., BOSTON, MASS.

Table IV gives a summary of the relative costs of a 1200-lb. station and a 400-lb. station taken from a recent analysis.

This analysis is given in the discussion, by Frank S Clark, of the paper, "Some Economic Factors in Power Station Design," by H. Boyd Brydon, Trans. A. S. M. E., page 169, Fuel and Steam Power, May-August, 1928, Vol. 50, No. 15.

TABLE IV

RELATIVE COSTS OF A 400-LB. AND A 1200-LB. PLANT—STONE & WEBSTER

	Per Cent of Total Station Cost	Increase for 1200 lb. Plant
General improvements, coal and ash handling	13.0%	None
Buildings and foundations	17.5	—5%
Turbine generators	17.5	5
Boilers, furnaces, and heat absorbing accessories	20.0	10
Fuel preparation, condensing and draft system	15.0	—15
	83.0%	balanced
Piping	6.0	25% 1.5%
Feed water system	3.0	50 1.5
Switching	8.0	20 1.5
Contingencies	....	1.0
	100.0%	5.5%

STATEMENT BY THE EDISON ELECTRIC ILLUMINATING CO. OF BOSTON

When the Edison Electric Illuminating Co. of Boston came to the construction of the Edgar Station at Weymouth, Mass., an exhaustive study was made to determine the most economical steam pressure and temperature.

The studies showed that it is economical to use steam at as high a temperature as possible, irrespective of the pressure employed. No estimates were made as to the exact increase in cost due to the use of the higher steam temperatures.

The studies as to the most economical pressure showed that for stations employing the regenerative cycle, but no reheating of the steam during its expansion from throttle to condenser pressure, there is no commercial economy in going to pressures higher than about 350 or 400 lb. at the turbine throttle. In other words, the fixed charges on the additional cost of the high-pressure equipment would be greater than the fuel savings due to the higher pressures.

When studied from the standpoint of the regenerative-reheat cycle, however, the studies indicated that there would be a decided commercial advantage in raising the operating pressure to somewhere between 1200 and 1500 lb.

Equipment for such pressures had never been built, and it was, therefore, impossible to estimate the cost of construction with a high degree of accuracy. Conservative estimates of the cost of construction indicated that 1200 lb. was justified, and one boiler and one turbine for this pressure were installed.

In 1926 it became necessary to start construction of an extension to the Edgar Station. In the light of construction and operating experience with 1200-lb. equipment, a careful study was again made to determine the most economical pressure for the extension. Three schemes were studied, as follows:

1. All 350 lb.
2. All 1200 lb.
3. One-half 350 lb. and one-half 1200 lb.

The actual cost of construction of a 1200-lb. installation was available, and the only unknown factors were how much the manufacturers had charged to development on the first 1200-lb. installation and how much could be saved by better design. When prices were obtained on the new equipment, it was found that by better design it was possible to reduce the unit cost of the high-pressure equipment, and that the estimates of the unit cost of construction of a 350-lb. and a 1200-lb. extension were closer than the probable accuracy of the estimates. The expected increase in economy, due to the 1200-lb. installation, had been realized, and it was, therefore, decided to install boilers for the extension designed to deliver all the steam at the turbine throttle at 1200 lb.

Experience in building the extension has confirmed the opinion that a properly designed 1200-lb. station need not cost any more per unit of capacity than a 350-lb. station. The increase in operating pressure, therefore, is justified.

Relative Cost of Various Parts of Steam-Electric Generating Station

The commercial economy of increasing the operating pressure has been questioned by many engineers almost every time in the past when the operating pressures have been raised. Probably the reason for this questioning lies in the fact that these engineers do not realize that the cost of a particular part of a station is less important than the actual unit cost of the complete station.

Fig. 17 shows the approximate split-up of the cost of the various parts of a normal pressure steam-electric generating station. A study of this chart throws a great deal of light on the reason why it is possible to build a 1200-lb. station for approximately the same unit cost as a 350-lb. station.

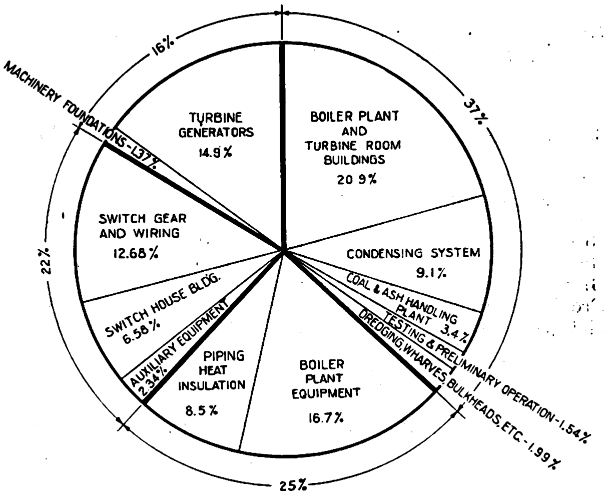

FIG. 17—RELATIVE COST OF VARIOUS PARTS OF STEAM ELECTRIC GENERATING STATION, EDISON ELECTRIC ILLUMINATING COMPANY OF BOSTON.

It is obvious that the unit cost of the switchgear and wiring, switch house and auxiliary equipment, which constitute 22 per cent of the cost of a station, have practically nothing to do with the operating pressure.

The cost of the turbine generators and equipment foundations will amount to slightly more for 1200 lb. than for 350-lb. equipment. These items only represent 16 per cent of the cost of the station, and the increase in unit cost is very small. Probably this slight difference in cost will disappear in the future.

The figures for boiler plant equipment and station piping, which constitutes 25 per cent of the cost of the station, will amount to more for a 1200-lb. than for a 350-lb. installation. The increase in unit cost is not as great as might be imagined, because of the fact that a 1200-lb. boiler will generate more kw. than a 350-lb. boiler of the same size. Furthermore, the cost of such equipment as fuel-burning equipment, ducts, cinder catchers and some piping, is much less per unit of capacity in a 1200-lb. plant than in a 350-lb. plant, and goes a long way toward balancing the higher cost of the pressure parts.

The boiler plant and turbine room buildings, condenser system, including intake and discharge tunnels, and coal and ash-handling equipment, which constitute approximately 37 per cent of the cost of a station, cost materially less per unit of capacity in a 1200-lb. than in a 350-lb. plant.

The additional cost of the various major parts which cost more in a high-pressure station was estimated and this sum was divided by the capacity of the high-pressure elements of the cross-compound turbine-generator units. This unit cost, roughtly obtained, is less than the unit cost of a normal pressure plant.

In conclusion, it can be said that our construction and operating experience shows that a properly designed 1200-lb. station need not cost any more per unit of capacity, and that it will show a material improvement in economy when compared with a 350-lb. plant.

Statement by E. B. Ricketts, The New York Edison Co., New York City

Table V gives an estimate of the relative costs of stations having varying steam pressures, other factors remaining constant. The writer has never built a high-pressure station.

Table V

Increased Costs per Kw. of High-Pressure Plants Over 400-Lb. Plants—E. B. Ricketts, The New York Edison Co.

Steam pressure, lb	1200	1200/400	1400
Capacity basis, kw	100,000	100,000	100,000
Greater cost for boiler and superheater,	$6.00	$3.60	$7.50
Greater cost for piping	4.09	4.09	4.24
Greater cost for turbine	1.00	0.80	1.25
Greater cost for feed water heaters	0.054	0.054	0.059
Credit for circulating system	0.52	0.51	0.52
Net greater cost	10.85	8.17	12.82

Statement by the Kansas City Power & Light Company

Relative Construction Costs of a 1400-Lb. and a 300-Lb. Installation

In considering the relative construction costs of a 1400-lb. and a 300-lb. plant, many problems arose to make it evident such a comparison was very much of a local one, and the difference in costs shown in Table VI are those which existed in this particular case and not necessarily what might exist elsewhere.

In this study a 45,000-kw. addition to an existing 300-lb., 130,000-kw. plant was considered, this to be either one 10,000-kw., 1200-lb unit, exhausting to a 35,000-kw., 300-lb. unit, or one 45,000-kw., 300-lb. unit. The figures do not include all the items that would appear in a new plant, but they do express the difference in cost per kw-hr. of the two pressures for the above installation.

No charges were made in either case for the building to house the 1200-lb. turbine and the two 1400-lb. boilers, or the three 300-lb. boilers, which were to be placed in an existing extension. The three 300-lb. boilers would have occupied more space, as the 1200-lb. turbine fitted into an unused space immediately adjacent to the 1400-lb. boilers, which simplified piping.

No credit was given the 1200-lb. unit for the reduction in coal handling and pulverizing costs.

These items are cited to show that the 300-lb. unit was favored, if anything.

Table VI

Relative Construction Costs of 1400-Lb. and 300-Lb. Installation

(Based on a 45,000-kw. addition to an existing station)

Item	1400 lb. Increase (+) Decrease (−)
Boilers, settings, economizers, air heaters, fuel burning equipment and soot blowers	+$7.39
Coal bunkers and coal conveyors	− 0.13
Building steel, foundations, floors, breeching, ducts, steel and pipe and duct insulation	− 0.19

Estimated B.t.u. per kw-hr. of 300 lb. plant	16,800
Estimated B.t.u. per kw-hr. of (45,000 kw.) 1400 lb.—300 lb. plant	13,810
B.t.u. saving on 1400 lb.-300 lb. plant	2,990
Load factor necessary to allow additional investment of $8.81 for 1400 lb.-300 lb. plant	33.8%

(Based on 15 per cent fixed charges and a fuel cost of 67,000 B.t.u. for one cent.)

The difference in condenser auxiliary power, boiler-feed pump, fan, coal handling and pulverizing power, is expressed in the net B.t.u. difference.

The summary indicates the 1400-lb. installation in this case would cost $8.81 per kw. more than the 300-lb. unit.

The table also shows the difference in B.t.u. for each of the installations and indicates the saving made by the 1200-lb. unit would pay 15 per cent fixed charges on the additional investment if it operated at only 33.8 per cent load factor. The actual load factor is, of course, dependent on the available load and the ability to keep equipment in service.

The load factor of the 1200-lb. unit should not drop off as rapidly as that of a 300-lb. unit over a period of years, as the obsolescence factor is undoubtedly lower.

The most economical point of operation of a 1200-lb. unit is at full load, and if the load is available a 70 per cent or 80 per cent load factor is entirely possible. Whether this or a 50 per cent load factor is used, the saving of a 1200-lb. unit over a 300-lb. unit is quite evident.

MANUFACTURERS' STATEMENTS

The Prime Movers Committee does not accept responsibility for any manufacturers' statement in this report.

STATEMENT BY THE GENERAL ELECTRIC COMPANY

The year 1928 has seen a remarkable increase in the use of higher steam pressures. This increase is shown graphically in Fig. 18 for both 600-lb. and 1200-lb. In the last two years about the same capacity of turbines has been ordered for each pressure, with the difference that the use of 600-lb. has been decreasing, while the use of 1200-lb. has been increasing rapidly.

The General Electric Co. has now installed, or on order, 19 units for 600-lb. and 9 units for 1200-lb., or a total of about 1¼ million kw. in 600-lb. units, and ¼ million kw. in 1200-lb. units.

A pioneer station designed exclusively for 1250-lb. is to be built by the W. S. Barstow Co., Inc., at Holland, N. J. The turbine is a 55,000-kw. cross-compound, 3600/1800 r.p.m. unit for steam conditions of 1200-lb., 725 deg. fahr., with boiler reheat to 750 deg. fahr. This turbine and the two 53,000-kw. units for the Deepwater Plant of the American Gas & Electric Co., and the United Gas Improvement Co., are similar in all essential respects.

A steam pressure of 1200 lb. for the turbines is working out so satisfactorily in the Edgar Station at Boston that a third 1200-lb. turbine is to be added. In order to obtain improved economy at light loads and better overall station efficiency, a 12,500-kw. turbine with multi-valve admission was selected rather than a duplicate of the recent single valve 10,000-kw. unit which, together with a 3000-kw. unit, is now operating in this station.

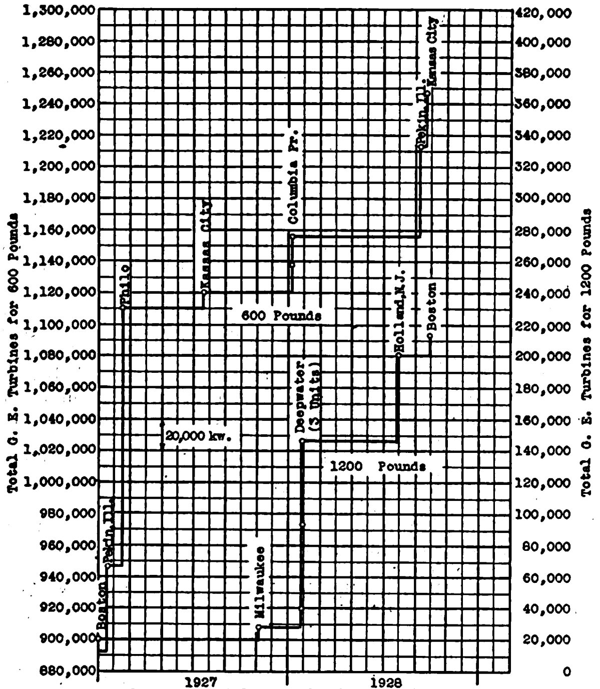

FIG. 18—COMPARATIVE SALES OF 600-LB. AND 1200-LB. UNITS, GENERAL ELECTRIC COMPANY.

The 208,000-kw., 600-lb. unit with steam reheat for the State Line Generating Co. has been tested and shipped and is now being installed.

A 165,000-kw., 600-lb. triple cross compound turbine is being installed in the Philo Station of the Ohio Power Co.

The 55,000-kw., 600-lb. unit of the Super Power Co. of Illinois is in service, operating satisfactorily, and a duplicate unit is under construction. The generators of these units were the first to be designed for 22,000 volts, and no difficulty has been experienced due to the high voltage.

In Buenos Aires the first of the two 52,000-kw. tandem compound turbines is in service. The second machine is about to be put in service. The steam conditions of 550 lb., 750 deg. fahr. with reheat to 750 deg. fahr. will result in an economy in this foreign station comparable with performance in the United States.

The Kansas City Power & Light Co. has in operation an unusual 10,000-kw. "reducing valve" turbine that receives steam at 590 lb. and 700 deg. fahr. and exhausts into the 190-lb. station mains. A 35,000-kw., single cylinder turbine for steam conditions of 590 lb., 700 deg. fahr., is being constructed for this company.

Steam Table Development

The demand for steam data at higher pressures and temperatures has been growing steadily. At the request of the A. S. M. E. Committee on Steam Research and the Extension of the Steam Tables, contributions were obtained from various operating companies and from manufacturers of turbines and boilers and others interested to finance the experimental work.

With the help and assistance of the Committee, the General Electric Co. has developed a steam chart which has been put at the disposal of the A. S. M. E. and is an additional contribution made by the General Electric Co. This was published in the February, 1926, issue of *Mechanical Engineering* for a range up to 1200 lb. and 750 deg. fahr.

Since then the additional experimental data obtained at the Massachusetts Institute of Technology and at the Bureau of Standards have made possible the extension of the steam tables and diagrams to 3500 lb. per sq. in. and 1000 deg. fahr. These were published in *Mechanical Engineering* for February, 1929, and copies can no doubt be obtained from the Committee having the matter in charge. The new charts meet the demand for a tabulation of the properties of steam covering the critical region and offering both thermodynamic consistency and faithfulness to reliable experimental data.

STATEMENT BY THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO.

Supplementing the information furnished last year concerning the 10,000-kw., 1200-lb. turbine for the Kansas City Power & Light Co., Fig. 19 shows the unit assembled in the shop; Fig. 20, the method of fastening and adjusting the clearance of reaction blading, and Fig. 21, sectional views of the thrust bearing, showing the means provided for adjusting the axial position of the rotor.

Fig. 19 illustrates the method of applying electrical heater elements to the large cylinder joint bolts to facilitate tightening to obtain definite bolt-stresses. The box wrench is shown in place on one stud, and two of the heater elements in place and a third partly withdrawn.

The blading shown in Fig. 20 is of the end-tightened type, but the fastening is a modified form of the old and well-known Westinghouse "hook type" root. The blades are made with an upset foot on the root which fits into a supplementary groove and extends under the packing piece. Packing of "shoulder-type" has superseded the old dovetail packing. Alongside the blades and the regular packing, special circumferential packing pieces are fitted, provided with a shoulder which projects above the rotor. This shoulder is turned after assembly to provide a surface for

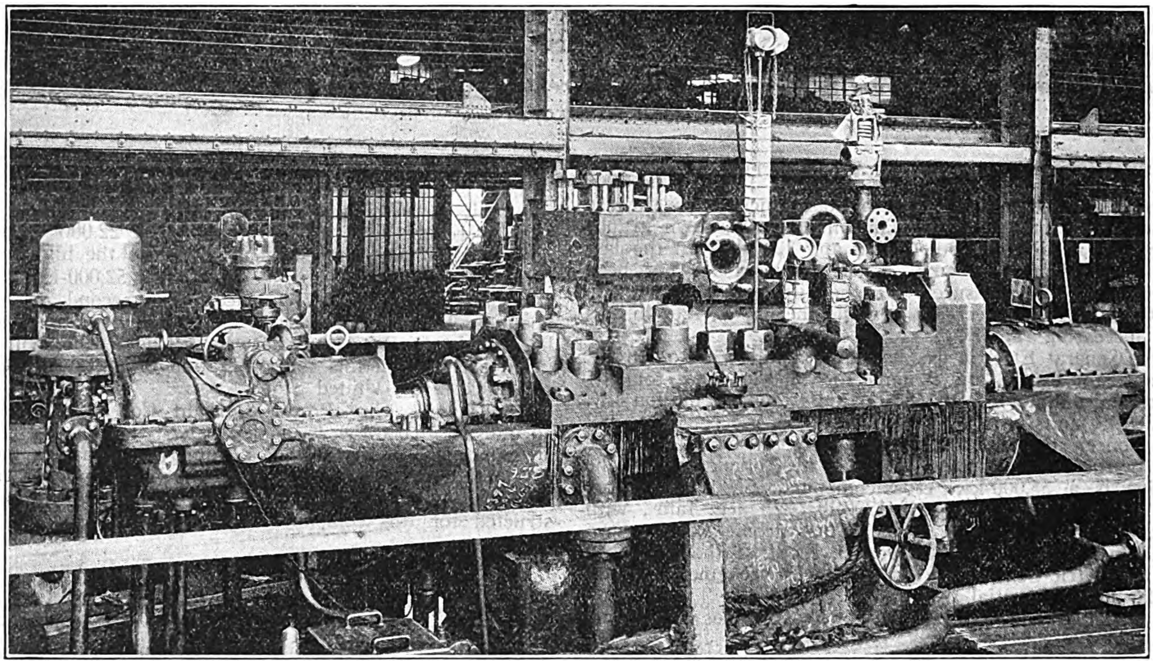

FIG. 19—10,000-KW., 1200-LB. WESTINGHOUSE TURBINE FOR THE KANSAS CITY POWER & LIGHT COMPANY.

the end-tightened shrouding of the complementary blade row to come up against.

Fig. 21 illustrates the construction of the thrust bearing, which is arranged to be capable of quick and easy adjustment, either to the running clearances, or to larger clearances, suitable for starting and stopping the turbine. This adjustment is facilitated by the provision of a hand wheel and indicator and by stops, located with the aid of shims when the shrouding is first ground in, to prevent excessive motion in either direction.

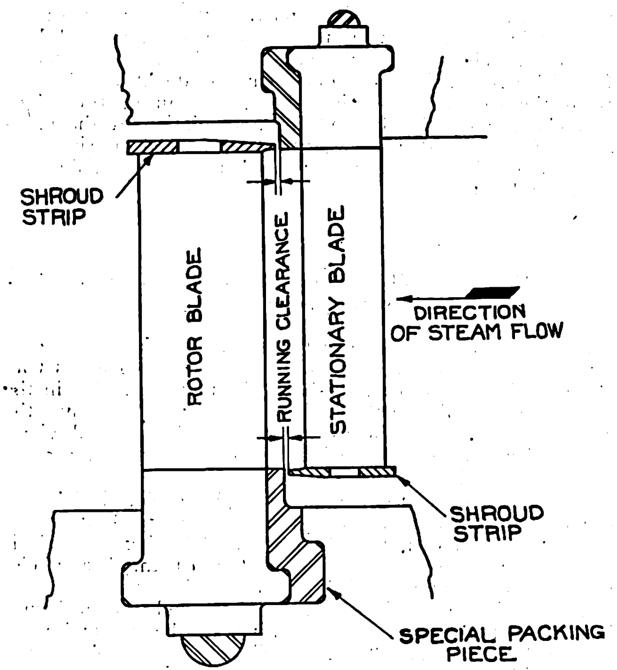

FIG. 20—METHOD OF FASTENING AND ADJUSTING CLEARANCE ON REACTION BLADING, WESTINGHOUSE ELECTRIC COMPANY.

STATEMENT BY THE BABCOCK & WILCOX CO.

Since the 1927-28 report, the Babcock & Wilcox Co. has received orders for a number of boilers for pressures above 600 lb.

The American Gas & Electric Co., United Gas Improvement Co. and Stevens & Wood have purchased for their Deepwater, N. J., Station six units built for 1400-lb. working pressure. Four of these units are standard boilers, Fig. 5, while two are reheat boilers, Fig. 6. All boilers are equipped with economizers, the standard boilers having economizers of the steaming type.

W. S. Barstow, Inc., has purchased for its Holland, N. J., Station two units built for working pressure of 1400 lb. Both of these are reheat boilers, the reheaters in this installation being a combination of convection and live steam reheaters in series to regulate reheat temperature under varying loads.

The Edison Electric Illuminating Co. of Boston has placed an order for two additional units for its Edgar Station built for 1400 lb. Both of these units are equipped with convection reheaters.

For process work the Masonite Corp. of Laurel, Miss., formerly the Mason Fibre Co., has placed an order for one additional unit of 3800 sq. ft. of heating surface, built for a working pressure of 1400 lb.

The drums of all of the boilers listed above are of forged seamless steel.

The Super Power Co. of Illinois has purchased for its Powerton, Ill., plant three additional units built for working pressure of 732 lb. Two of these units are standard boilers, while the third is a reheat boiler. The drums of these boilers are riveted.

With reference to superheat temperatures in practically all of the central station boilers purchased during the year, such temperatures have been in excess of 700 deg. fahr., the majority of the units being designed to give between 725 and 750 deg. fahr. In the case of the reheat boiler unit, the temperature of the reheated steam has also been above 700 deg. fahr. Such temperatures have ordinarily been 750

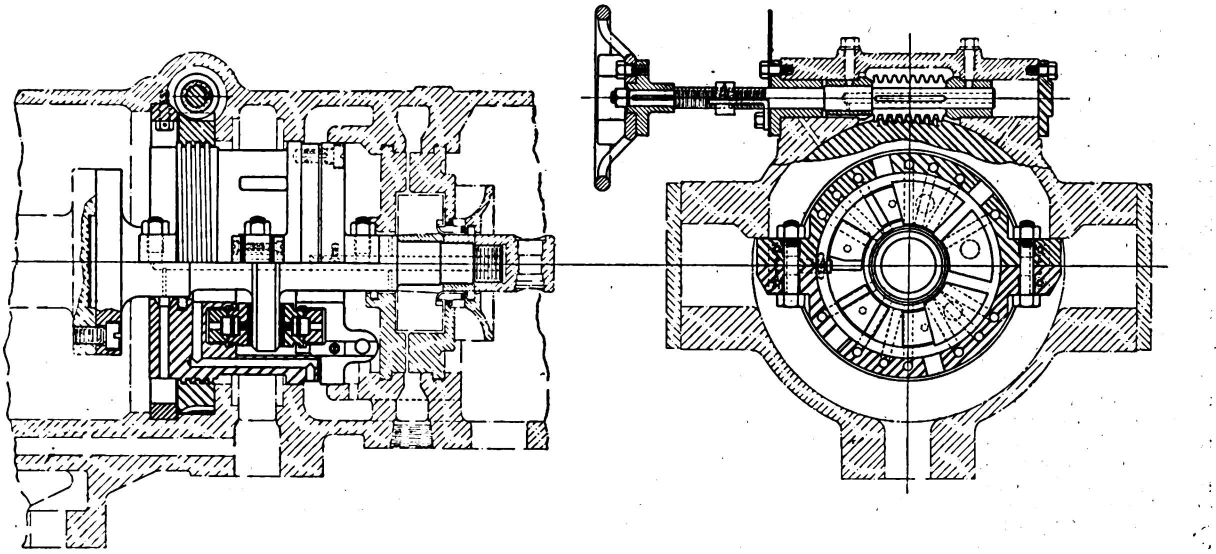

FIG. 21—THRUST BEARING, SHOWING THE MEANS FOR ADJUSTING AXIAL POSITION OF ROTOR, WESTINGHOUSE ELECTRIC COMPANY.

deg. fahr., and in some instances 775 deg. fahr., whereas for a few contemplated installations 800 deg. fahr. reheat temperatures are being considered.

The maximum ultimate temperature of the primary superheat that has been used up to this time in this country has been 750 deg. fahr., though here also higher temperatures are being considered for contemplated installations.

One exception to this statement should be made. A separately fired superheater for experimental work has been purchased and installed during the year, designed to give an ultimate temperature of 1100 deg. fahr. This unit has not as yet been placed in service.

In industrial plants ultimate temperatures in excess of 700 deg. fahr. are rare, except in such installations as combine high-pressure turbines with the use of process steam.

A great number of superheaters are in service today giving steam temperatures in primary superheaters of 750 deg. fahr., and in a few reheater units giving temperatures of 775 deg. fahr. Plain steel has been found satisfactory in superheaters where the ultimate temperatures have not exceeded 700 deg. fahr., or slightly more. Above this temperature, where superheaters have been placed in zones of high temperature and high rates of heat transfer, an alloy steel known as Enduro KA-2 (formerly known as Enduro 18-8, 18 per cent chrome, 8 per cent nickel steel) has been used for the past year. This material has given very satisfactory results in service.

Enduro KA-2 billets are manufactured for this company by the Central Alloy Steel Corp., which, with the Ludlum Steel Co. and the Babcock & Wilcox Tube Co., are licensed under the Krupp Nirosta patents, the material being produced under the supervision of Prof. Benno Strauss of Krupp, A. G., Germany.

As a result of the increasing demands for high temperatures, the superheaters have been redesigned so as to make it possible to satisfactorily increase the total steam temperatures with plain steel tubes, and if the limits of such metals are reached, to permit the use of special materials for a smaller percentage of the superheater.

In this design there is but a single row of tube holes in the inlet and outlet headers, each tube being continuous from the inlet to the outlet without intermediate boxes. This permits the total pressure drop to be expended in the flow of steam through the tubes without intermediate points interfering with the distribution thus obtained. Further, this construction eliminates the necessity of distribution baffles or ferrules.

With the new design of superheater short radius tube bends, which would maintain a proper cross sectional area through the tube in the bend and also maintain the proper tube gage on the bend, are required, and a new method was developed by the company to make possible this construction.

While it is appreciated that the majority of superheaters in high-pressure plants seldom, if ever, require cleaning, the evidence is that occasionally, when something unforeseen occurs, such cleaning is necessary, and the new type of superheater is designed to permit thorough turbine cleaning. This is accomplished by the use of a Y-type return bend on one end of each loop, each Y being fitted with a valve of simple and approved design which can readily be opened for turbining when necessary. The location of these valves is such as to be outside of the range of stresses caused by heating and cooling, and the entire fitting is protected from soot and ashes. The superheater as arranged is completely drainable.

Where temperatures are beyond the limit where expanded joints will remain tight, the outlet superheater tubes can readily be welded to the header.

One of the problems in connection with the design of superheaters to give a minimum pressure drop is that of proper steam distribution. A step in advance, in this respect, in the new design of superheaters is made by bringing the steam from the drum to the inlet header through a number of tubes along the length of the header, these tubes being located inside of the tube doors. This method of bringing the steam to the inlet header gives an improved distribution of the steam. Further improvement in distribution is obtained by making use of a large diameter outlet header, a source of supply for such headers now being available. A combination of these features results in a design of superheater that has practically no distribution problem.

By bringing the steam to the superheater tubes exposed to the greatest amount of radiation and to the hottest products of combustion, it will be possible to maintain the superheater in relatively close proximity to the furnace with a resulting flat superheat-output curve, still have a considerable margin of safety with this design over previous designs, and still permit of ultimate steam temperatures higher than those now in use with plain steel tubes, and still higher if alloy tubes are used.

It is felt that the combination of the shutter steam drum baffle, described in a statement in the 1928-29 Report of the Subcommittee on Boilers, Superheaters and Economizers, the arrangement for taking steam from the drum along its length through tubes instead of steam pipes, the supplying of steam to the inlet header entirely within the setting and throughout its length, brings together the development of steam separation, minimum pressure drop and maximum superheat for any location in the boiler, all of which factors have resulted in the most satisfactory type of unit for high-pressure service.

A development in economizer design of last year was a change in design of return bends. Formerly these bends were made of seamless steel tubing with threaded flanges on the ends having female facings. Now they are forged from round bar stock with the flanges integral. The flanges are produced on the ends of the bar by the upset forging process. After the flanges are formed, and before bending, the blank is drilled from end to end making it a seamless tube.

Special devices are used in forging and bending to insure the faces of the flanges being in the same plane after bending and having the same angularity, as well as maintaining uniform center distances of the ends.

The return bends for connecting the top and bottom rows of tubes to the headers were formerly made of seamless steel tubing with threaded flanges each end, one end having male and other female facing.

In order to eliminate threaded flanges throughout on the return bends, and at the same time to produce a return bend for the header connections more adaptable to the location than the solid forged bend, a type of bend has been developed having loose flanges and facing similar to the Van Stone type. These bends are of seamless tubing, upset on the ends and having loose fitting bolting flanges bearing against the upset ends, one end being faced for male and the other for female connection.

STATEMENT BY THE COMBUSTION ENGINEERING CORP.

"Two notable high-pressure installations have been placed in service since the 1927-28 Report. These are at the Grand Avenue and Northeast plants of the Kansas City Power & Light Co., Kansas City, Mo.

The Grand Avenue installation consists of three 15,160-sq. ft. Ladd boilers, designed to operate at 700 lb. per sq. in., each with 2250 sq. ft. of water-cooled wall surface, 9148 sq. ft. of fin tube economizer surface and 2550 sq. ft. of superheater surface. Each unit has 22,060 sq. ft. of C. E. air preheater surface and is fired by one 24-ft. wide and 22-ft. long Green forced draft stoker. The normal steam rate is 150,000 lb. per hr., and the maximum rate 225,000 lb. per hr. per boiler. At these ratings, the various temperatures are shown in Table VII.

TABLE VII

EXPECTED TEMPERATURES, 700-LB. GRAND AVENUE STATION BOILERS, KANSAS CITY POWER & LIGHT CO.

	150,000 lb. per hr.	225,000 lb. per hr.
Final steam temperature	740	750
Water entering economizer	210	210
Water leaving economizer	287	289
Air entering preheater	70	70
Air leaving preheater	295	350
Gas leaving preheater	280	323

The installation at the Northeast Station consists of two Ladd boilers with 16,950 sq. ft. of heating surface each, designed to operate at 1400 lb. pressure. Each unit has 3050 sq. ft. of furnace water cooling surface, 10,891 sq. ft. of fin tube economizer surface, 2650 sq. ft. of primary superheater surface and 470 sq. ft. of reheater surface. Two plate type C. E. air preheaters having 39,270 sq. ft. of heating surface each supply air for combustion. Each unit is fired by three Raymond impact mills, giving 45,000 lb. of coal per hr. total maximum capacity. At normal rating, the unit will deliver 170,000 lb. of steam per hr., and at maximum rating, 200,000 lb. per hr. The temperatures for these ratings are shown in Table VIII.

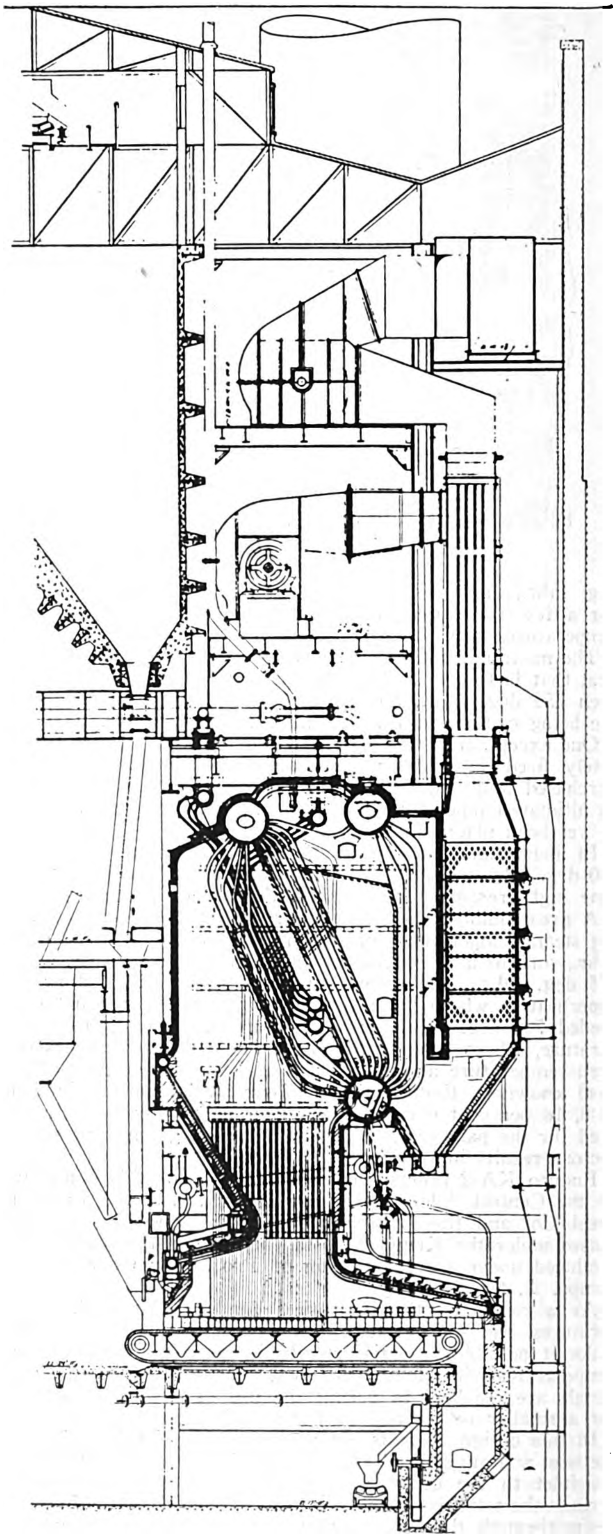

FIG. 22—CROSS SECTION OF 700-LB. UNIT AT GRAND AVENUE STATION.

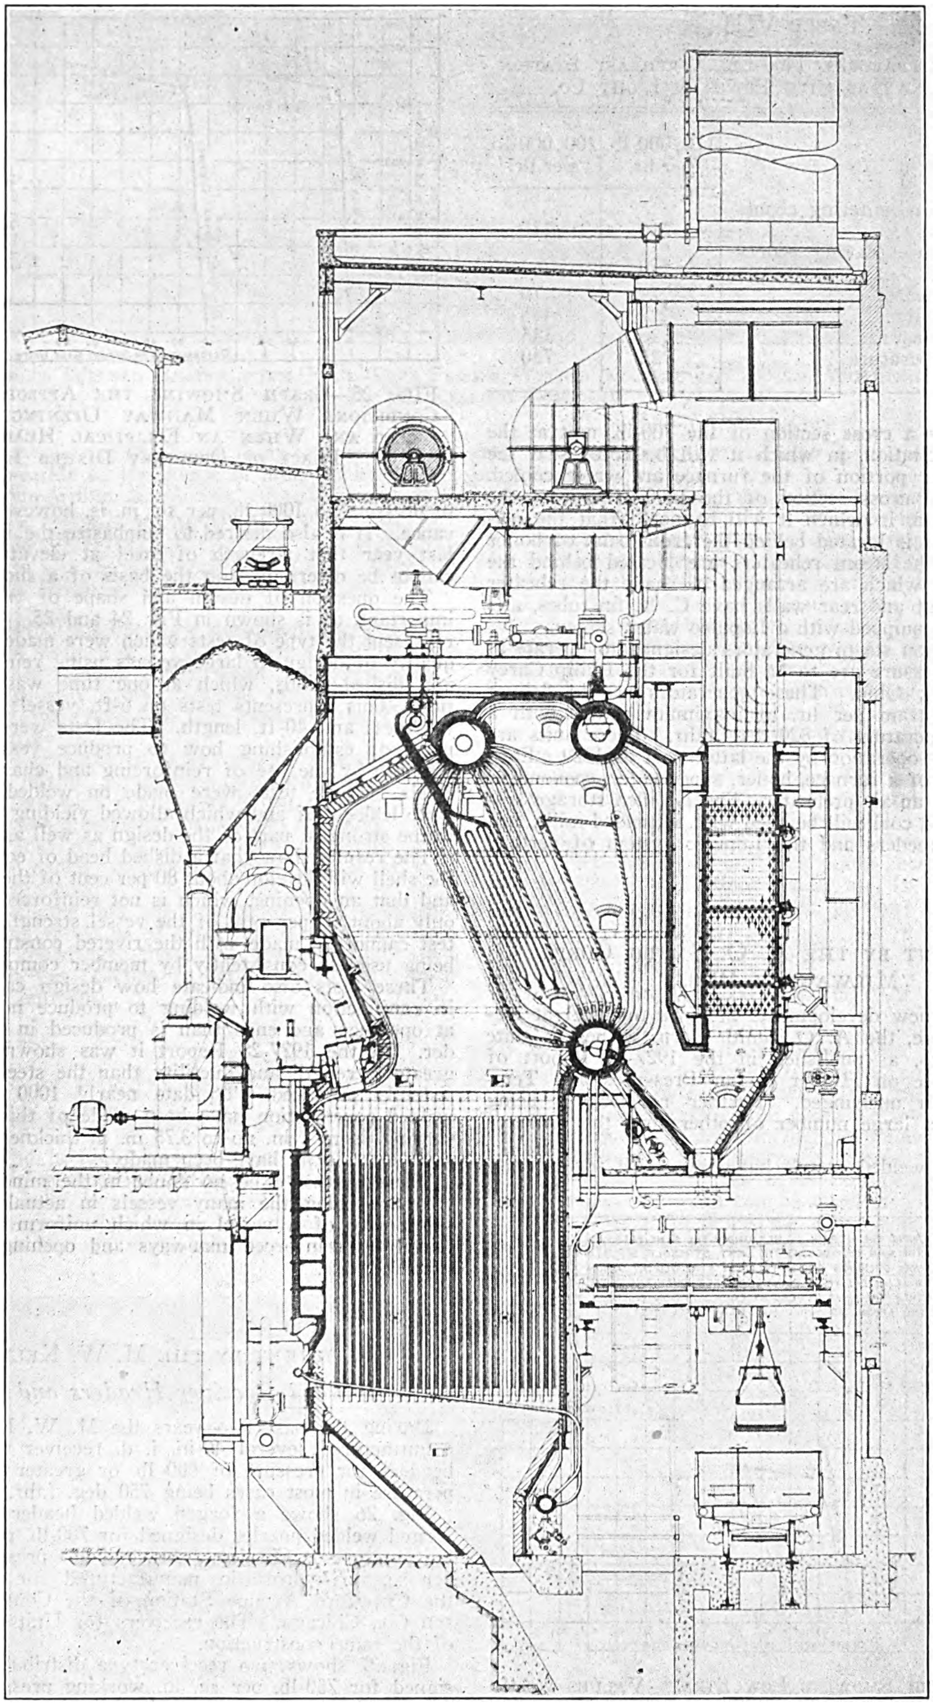

FIG. 23—CROSS SECTION OF 1400-LB. UNIT AT NORTHEAST STATION.

TABLE VIII

EXPECTED TEMPERATURES, 1400-LB. NORTHEAST STATION BOILERS—KANSAS CITY POWER & LIGHT CO.

	170,000 lb. per hr.	200,000 lb. per hr.
Water temperature entering economizer	210	210
Water temperature leaving economizer	319	324
Air entering preheater	70	70
Air leaving preheater	412	435
Gas leaving preheater	328	345
Total steam temperature	725	730

Fig. 22 shows a cross section of the 700-lb. unit at the Grand Avenue Station, in which it will be noted that the arches and upper portion of the furnace are water cooled. Fig. 23 shows a cross section of the 1400-lb. unit at the Northeast Station, in which it will be noted that the primary superheater is located behind the front bank of boiler tubes and that the steam reheaters are located behind the side wall tubes, which are arranged to shade the reheater tubes. The front and rear walls have C. E. fin tubes, and each furnace is equipped with a Lopulco water screen.

Two Combustion steam generators designed to operate at 1840-lb. gage pressure are to be built for the Philip Carey Co. at Lockland, Ohio. These generators are to deliver 150,000 lb. of steam per hr. at maximum rating with a total steam temperature of 820 deg. fahr. These units are expected to start operation by the latter part of 1929. Each unit will consist of a furnace, boiler, superheater, economizer and settings and an air preheater. The Lopulco storage system of pulverized coal will be used with Raymond mills, Lopulco Type R feeders and the Lopulco system of vertical firing.

STATEMENT BY THE A. O. SMITH CORP., MILWAUKEE, WIS.

Referring to new developments in work on steel at elevated temperature, the A. O. Smith Corp. wishes to state that the findings, as published in the 1927-28 Report of the Subcommittee on Higher Steam Pressures and Temperatures remain unchanged. Further research is being carried out on a large number of other than the ordinary carbon steels.

The fact that welded vessels have been built for increase in pressure to 1000 lb. per sq. in. is, however, a step in advance. It is also desired to emphasize the fact brought out last year that strength of steel at elevated temperatures cannot be determined on the basis of a short time test.

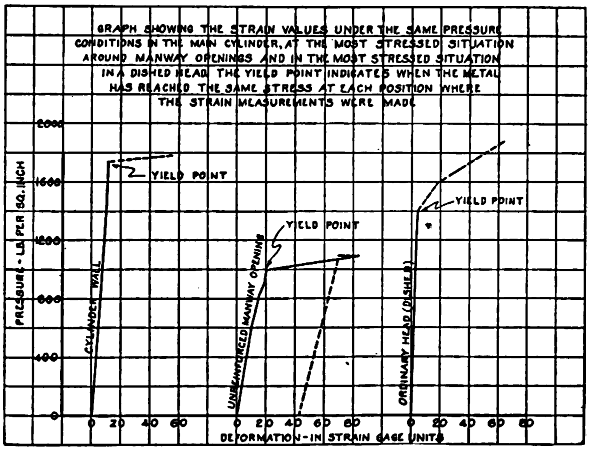

FIG. 24—GRAPH SHOWING LOW STRAIN VALUES WITH ORDINARY DISHED HEAD AND UNREINFORCED MANWAY OPENING.

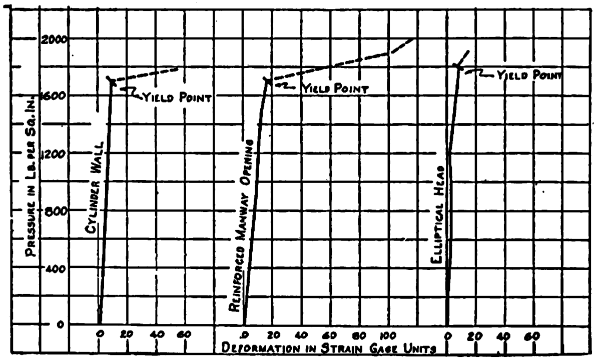

FIG. 25—GRAPH SHOWING THE APPROPRIATE STRAIN CONDITIONS WHEN MANWAY OPENINGS ARE REINFORCED AND WHEN AN ELLIPTICAL HEAD IS USED IN PLACE OF ORDINARY DISHED HEAD.

The question of design and shape of vessels is equally important, as is shown in Fig. 24 and 25. These diagrams represent the type of tests which were made to evaluate the quality of design in large vessels using reinforced openings and dished heads, which at one time was common practice. This represents tests on 6-ft. vessels with 2-in. wall thickness and 40-ft. length. The tests were carried to the point of establishing how to produce vessels uniform in strength by the use of reinforcing and change of shape of heads. These tests were made on welded vessels, which were leak-proof and which allowed yielding to be developed in the strongest part of the design as well as in the weakest.

The results show that a dished head of equal thickness as the shell will develop about 80 per cent of the vessel strength and that an opening, which is not reinforced, could develop only about 60 per cent of the vessel strength. This type of test cannot be made with the riveted construction which is being used so consistently by member companies.

These tests also indicate how design can be developed in conjunction with welding to produce no greater stress at openings and ends than is produced in the main cylinder. In the 1927-28 Report it was shown that welds of greater strength and ductility than the steel had been consistently produced. To date nearly 1000 vessels of this welded construction have been made of thick wall sections varying from 2 in. up to 3.75 in. in thickness. A few sections up to 6 in. have been made.

There seems to be no doubt in the minds of customers who are using the many vessels in actual service of the superiority of a vessel in which uniform strength is obtained by reinforced manways and openings and properly shaped heads.

STATEMENT BY THE M. W. KELLOGG CO.

Welded Receiver Headers and Drums

During the past two years the M. W. Kellogg Co. has manufactured several 40-in. i. d. receiver type distributing headers for pressure of 600 lb. or greater; operating temperature in most cases being 750 deg. fahr.

Fig. 26 shows a forged welded header with flue type forged welded nozzles designed for 700-lb. per sq. in. working pressure at 650 deg. fahr., and test pressure of 1050 lb. per sq. in. hydrostatic, manufactured for Unit No. 6 at the Crawford Avenue Station of the Commonwealth Edison Co., Chicago. The receivers for Units No. 1 to 5 are of the same construction.

Fig. 27 shows two receiver type distributing headers designed for 750-lb. per sq. in. working pressure at 750 deg. fahr. and test pressure of 1200-lb. hydrostatic, manufactured for the Philo Station of the Ohio Power Co.

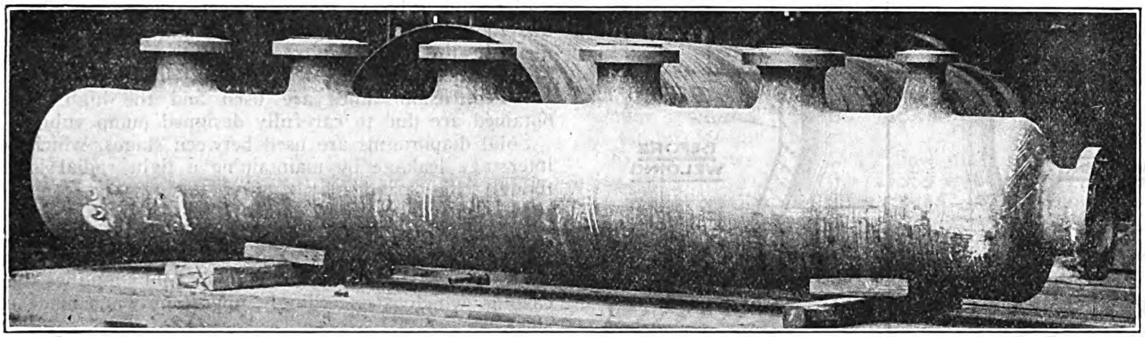

FIG. 26—FORGED WELDED HEADER WITH FLUE TYPE FORGED WELDED NOZZLES FOR 700-LB. WORKING PRESSURE, THE M. W. KELLOGG COMPANY.

Because of the weakness of the shell, it was necessary to reinforce the knuckle of the nozzle in order to keep the stresses at this point within safe limits. Fig. 28 shows details of reinforcing nozzle, the type in this case being as shown in final stage "A."

Forged and Hammer Weld Boiler Drums

In November, 1927, this company furnished to the Edge Moor Iron Co. two 48-in. i. d. x 1¼-in. thick x 31-ft. long-forged and hammer welded boiler drums, together with sixteen 36-in. i. d. unit drums. These drums were for 350-lb. boilers for the Oklahoma City plant of the Oklahoma Gas & Electric Co.

This company is prepared to build hammer welded boiler drums from steel having a minimum ultimate strength of 50,000 lb. per sq. in., with a thickness at the welds not to exceed 2 in. Maximum diameter made from one plate with only one longitudinal weld is 54 in. All materials and workmanship to be exactly in accordance with A. S. M. E. Boiler Construction Code.

This company believes that the mention of these hammer welded boiler drums would be of great interest for the reason that, to its knowledge, these are the first built in America, although the practice is very common in Germany and on the Continent.

STATEMENT BY THE INGERSOLL-RAND CO.

High-Pressure Pumping Equipment

The present trend in high-pressure boiler feed seems to be away from variable speed on the boiler feed proper, both on account of the large horsepower involved, and the high speed, 3600 r.p.m., generally required to generate the high pressures. This makes the electrical control very expensive, both as to first cost and also as to space required for installation.

The alternative is to run the boiler feed pump at constant speed and place ahead of it a booster or tank pump of comparatively low pressure and horsepower, equipped with variable speed motor and having such hydraulic characteristics that the entire regulation of the load can be accomplished through this preliminary pump at moderate cost, owing to its lower horsepower rating.

Such an arrangement has been worked out for the Deep Water plant now being designed. The equipment consists of six-stage medium pressure, adjustable speed pumps, each delivering 650,000 lb. per hr. at 670-lb. pressure, to No. 6 five-stage cast steel, high-pressure pumps, which increase the pressure to 1550 lb. All pumps will have Kingsbury thrust bearings and pressure lubrication. The boosters will have 850-h.p. motors and the boiler feeds proper 1250-h.p.

Fig. 29 shows the No. 4 Class "HT," six-stage boiler feed pump furnished the Kansas City Power & Light Co. for its Northeast Station. This pump receives its supply from the 350-lb. boiler feed header and is designed to deliver 400,000 lb. per hr. at 1500-lb. pressure and 3600 r.p.m.

STATEMENT BY THE DELAVAL STEAM TURBINE CO.

On high-pressure pumps of the type shown in Fig. 30, built to supply 800 g.p.m. at 3600 r.p.m. when operating against a discharge pressure of 1500 lb., no thrust bearing is either required or recommended. For the hydraulic balance to function properly, the clearance must be such that thrust bearing would not function; consequently no forced feed lubrication or oil coolers are necessary.

The hydraulic balancing device compensates for wear and the amount of wear can be checked without removing the pump cover. To bring the rotor back to its original operating position it is necessary to replace the balancing

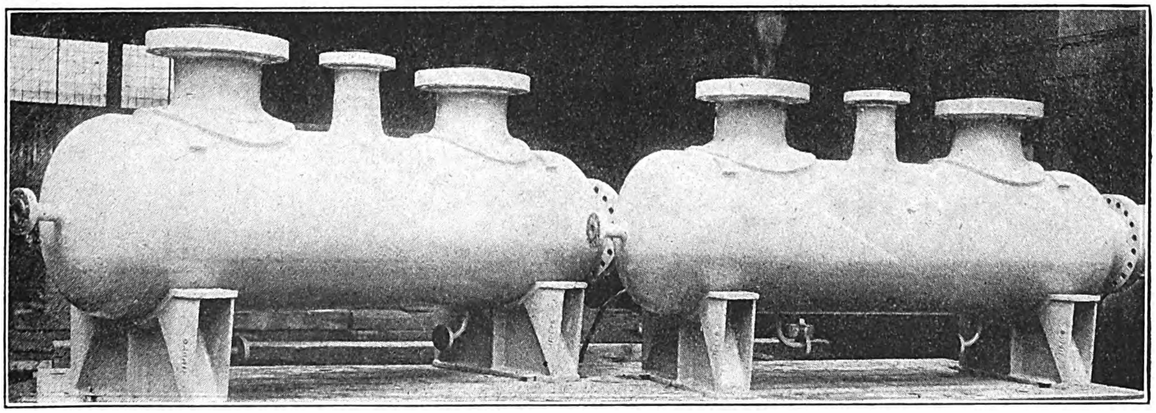

FIG. 27—RECEIVER TYPE DISTRIBUTING HEADERS FOR 750 LB., THE M. W. KELLOGG COMPANY.

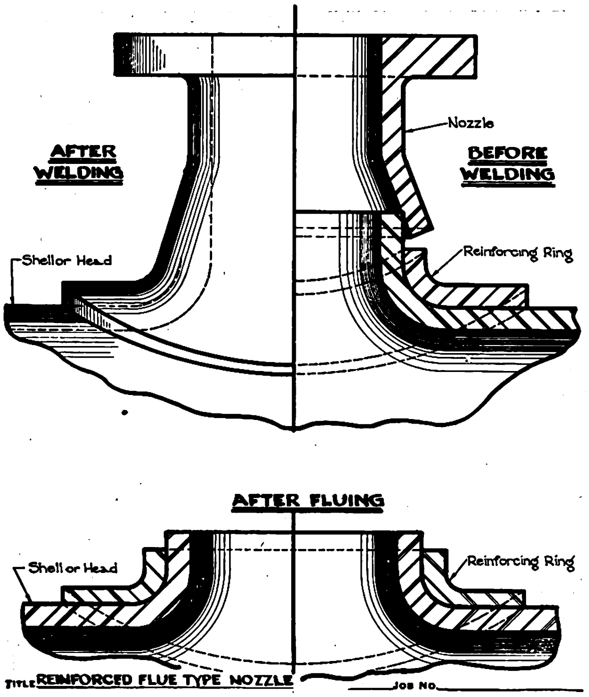

FIG. 28—DETAILS OF REINFORCING NOZZLE, THE M. W. KELLOGG COMPANY.

piston and case ring. This has never been necessary because of wear, although a large number of pumps of this type have been in boiler feed service for a great many years.

Other features of construction are cast steel center line supports for the casings and heavy pedestal bearings, mounted directly on the base plate to support the pump rotor. This construction insures proper alignment under all conditions of operation.

The stuffing-boxes are under suction pressure only. When this suction pressure is relatively high, a bleed-off arrangement in the stuffing boxes, which is patented, takes care of the external leakage.

No diffusion vanes are used and the high efficiencies obtained are due to carefully designed pump volutes.

Solid diaphragms are used between stages, which reduces interstage leakage by maintaining a tight radial joint even though the casing may expand under pressure. Fig. 31 shows one of the four turbine-driven boiler feed pumps supplied the State Line Generating Co. for 800 lb., discharge pressure, 950 g.p.m. Both turbine and pump casings are made of cast steel. The solid diaphragm simplifies the pump casting, which is exceedingly important when made of cast steel.

No matter how heavy the bolting, interstage leakage is usually present in a horizontally split pump where the complete diaphragm is a part of the casing.

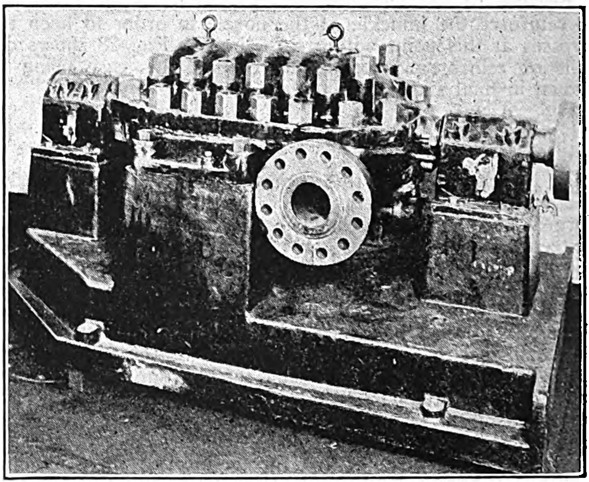

FIG. 30—1500-LB. BOILER FEED PUMP, DELAVAL STEAM TURBINE COMPANY.

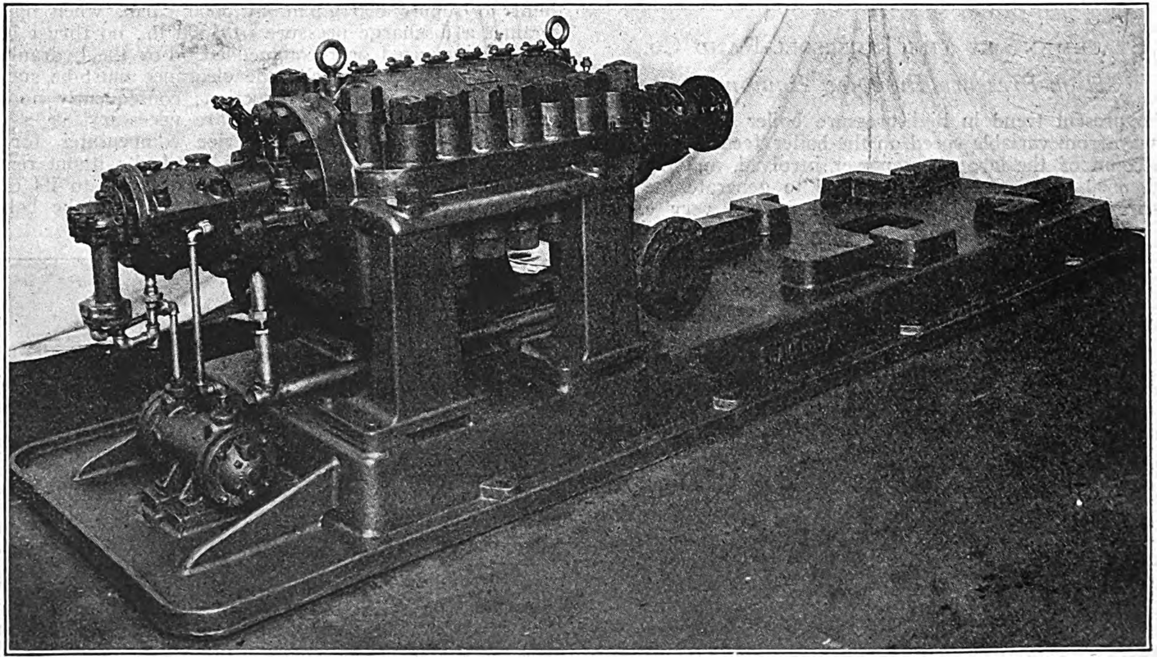

FIG. 29—NO. 4 CLASS "HT" 1500-LB. PRESSURE PUMP, INGERSOLL-RAND COMPANY.

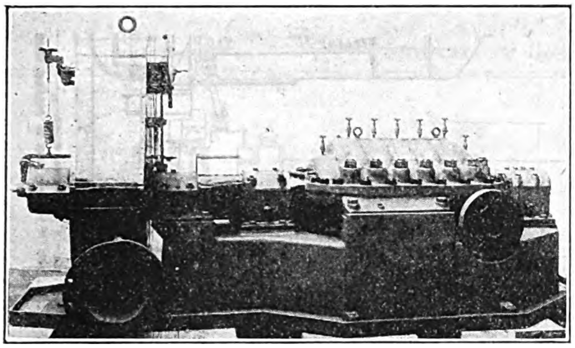

FIG. 31—800-LB. BOILER FEED PUMP, DELAVAL STEAM TURBINE COMPANY.

STATEMENT BY THE SWARTWOUT CO.

Fig. 32 shows a sectional view of the Swartwout feed water regulator furnished the Kansas City Power & Light Co. for its two 1400-lb. boilers at Northeast Station; a similar type was furnished for the three 700-lb. boilers at its Grand Avenue Station.

Fig. 33 shows a sectional view of the Swartwout Type S-E valves furnished the above stations for maintaining a constant excess pressure (above steam drum pressure) at the feed water regulating valves. The S-E valves are placed in the feed lines to the economizer and also serve to prevent excessive feed pump pressure building up in the economizer and popping the safety valves.

The Swartwout regulators installed on the Edgar Station boilers were the first regulators put on boilers of so high a pressure and are giving very satisfactory service.

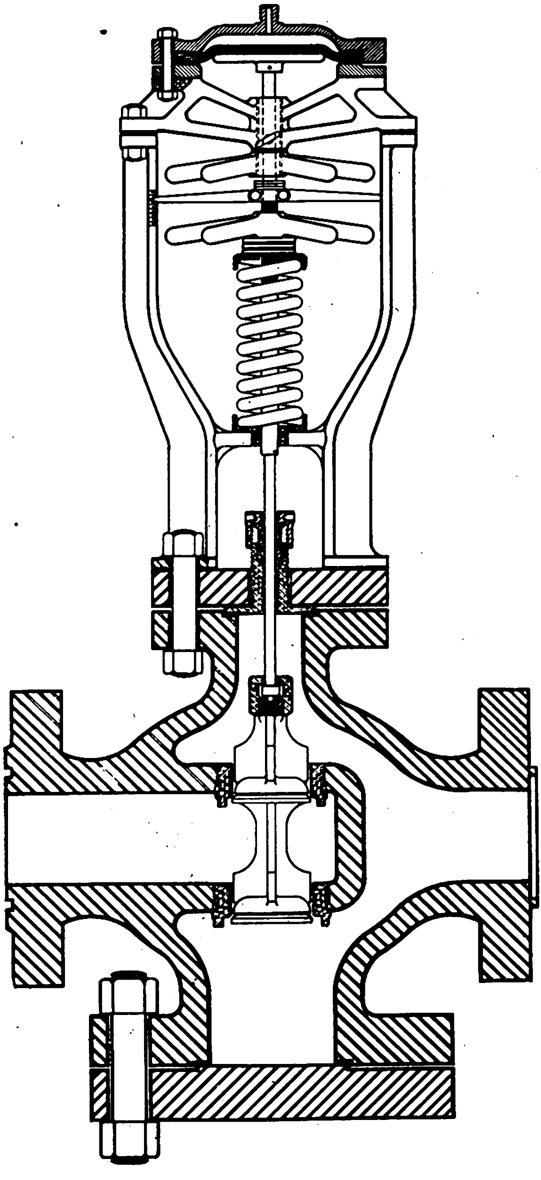

FIG. 32—FEED WATER REGULATOR FOR HIGH-PRESSURE SERVICE, THE SWARTWOUT COMPANY.

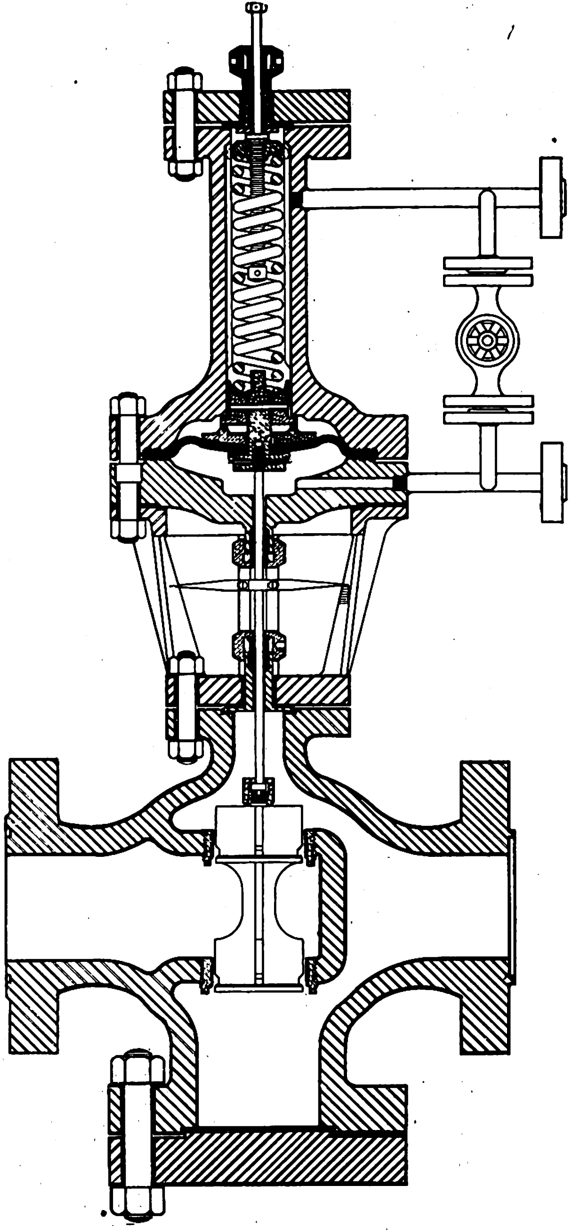

FIG. 33—TYPE S-E CONSTANT EXCESS PRESSURE REGULATOR FOR HIGH-PRESSURE SERVICE, THE SWARTWOUT COMPANY.

The Doble High Pressure Steam Generator

STATEMENT BY SYDNEY W. TAYLOR, JR., CONSULTING ENGINEER, SAN FRANCISCO, CAL.

The most fruitful field to explore in order to bring about notable increases in power plant efficiency is the field of high-pressure, high-temperature steam. The results of modern trends in central station practice prove the accuracy of this statement. But designers, seemingly, are reluctant to depart from conventional boiler types with their steam drums and attendant metallurgical difficulties; their natural circulation and priming propensity. Obviously, the generation of steam within the walls of a single tube, coiled and placed in series with the counter-flowing gases, would eliminate metallurgical difficulties, and no entrained water could carry over to the steam line if the delivery temperature were maintained above that of saturation. But boilers of this kind, generally speaking, have fallen into disrepute for want of the development of reliable pressure and temperature controls. The following describes a practical steam generator of the single tube type and a simple, unfailing system of automatic control, developed by the Doble Steam Motors Corp. of Emeryville, Cal. The generator is in successful use in the power plant of that concern's steam automobile.

Design

Fig. 34 shows a diagrammatic vertical section of the Doble automobile boiler, and Fig. 35 a similar view of a boiler proposed for a locomotive of main line proportions, designed to deliver 80,000 lb. of steam per hr. at 1500-lb. pressure and a temperature of 800 deg. fahr. The rear unit of the locomotive, which carries an air-cooled condenser, is omitted. The small automobile boiler will deliver steam at any desired temperature within reason. Service temperatures above 900 deg. fahr. are not beyond its maximum range. It has been operated in the laboratory at pressures well above the critical point and at ratings up to 2200 lb. per hr., equivalent evaporation. In normal service, however, furnishing steam for the double cross-compound engine of the automobile, its controls are set to

12. Weight of flue gas, lb. per hr	860	1,190	1,380	1,790	2,100	2,440
13. Gas per average sq. ft. of gas passage area, lb. per hr.*	1,310	1,810	2,100	2,730	3,200	3,720

*The average gas passage area is 0.656 sq. ft.

deliver at 850 deg. fahr. and, usually, not more than 850 lb. Its heating surface is 80.4 sq. ft. (See Tables IX and X for other data.) The Doble boiler is adapted to use of liquid or colloidal fuel and dry, powdered coal. The locomotive unit is designed for oil; the small unit burns gasoline, since gasoline is always readily obtainable at filling stations.

The boiler consists essentially of a single tube of seamless steel, gradually expanding in diameter from the inlet to the discharge as the separate tube lengths are welded together. Fig. 34 and 35 show this tube formed into a series of open-wound flat coils and a single close-wound helical coil, the arrows indicating the direction of circulation. The coils are disposed in an insulated cylindrical casing in such a way that the working fluid in its progress through the tube is constrained to flow counter to flow of the gases. The draft and the feed are both forced. The flat coils occupy the convection section of the boiler; the helical coil gives shape to the furnace and functions as a water-cooled lining. A thermostat element, the housing of which is placed in series with the path of the fluid near the point of steam delivery, controls the rate of heat liberation. The locomotive boiler is equipped with an air preheater.

It will be seen that the several steps in the process of steam generation, that is to say, the heating of the feed to steam formation temperature, its gradual conversion to vapor, its subsequent superheating to the temperature predetermined by the setting of the thermostat contacts—all take place successively within the walls of a single tube. The boundary planes, therefore, which mark the beginning of steam formation and the beginning of superheat, are not definitely fixed, but shift their positions automatically as operating conditions vary, the amount of movement back and forth being governed by the pressure and quality of the steam delivered, the temperature of the feed and the rate at which the boiler is driven. It would be impossible, of course, definitely to locate these boundary planes—nor are we concerned with their exact location. Nevertheless, we are able to determine the extent of the three zones of the process with fair accuracy by making certain assumptions. Fig. 36 represents an attempt at such a determination for the locomotive boiler, the assumptions made being also given. The tube itself is shown diagrammatically in development with its several diameters greatly exaggerated, and the curves indicate what is taking place within the boiler, thermally and mechanically.

Control

The operation of the control system rests upon the principle that the rate of feed in a boiler should vary with the

TABLE X

SUMMARY OF CALCULATED BOILER PERFORMANCE DATA, DOBLE CLASS D-1 AND D-2 LOCOMOTIVE BOILER

1. Actual evaporation, lb. per hr	20,000	35,000	50,000	65,000	80,000
2. Equivalent evaporation per sq. ft. of total surface, lb. per hr	7.50	13.13	18.74	24.34	30.05

heat liberated, the ratio of the two being in proportion at any given load to the boiler's operating efficiency at that load. Fig. 37 shows the control diagram of the locomotive boiler. With a single exception, which is noted in passing, the system is in all respects similar to the one in successful operation on the small automobile boiler. The following numbered paragraphs clarify the notation and symbols of the diagram.

1. Connections and mechanisms are diagrammatic only; they merely illustrate the method and sequence of operation. For this reason solenoids are shown rather than apparatus perhaps more appropriate, and relays are omitted for the sake of simplicity.
2. The standby burner is entirely independent of the main controls. It serves as a pilot, and, in addition, delivers the fuel necessary to offset standby radiation and other heat losses; and it keeps the compressors in operation when the locomotive is standing or drifting.
3. The forced draft blower turbine throttle (not shown), is manually operated to maintain suitable pressure in the windbox, the amount of throttle opening being dictated by the color of the stack gases.
4. The main control levers and rods are adjustable both as to leverage and linkage. Once adjusted, they should require only infrequent changes
5. The temperature fire control solenoid is set to cut the air supply to half of whatever quantity happens to be passing at the time of its functioning. The temperature fire control oil shunt valve is set to pass half of the normal full-load requirement of oil.
6. Mechanical burners of the constant orifice pressure type are employed.

The main control lever in the diagram happens to be shown at half load, although any other setting would serve to illustrate the principle of operation just as well. Assume that all adjustments of leverage and linkage have been made. The air and fuel controls, then, permit the delivery, as nearly as may be, of oil and air at rates sufficient to sustain the fire at half load. The compensator valve at any setting of the control lever passes an amount of water just short of sufficient to satisfy the boiler's need, the deficiency being regulated by the adjusting orifice of the compensator. The delivery temperature rises, therefore, and when it reaches 820 deg. fahr., the normalizer contact of the thermostat makes and causes the normalizer valve to open and admit small quantities of water into the superheater coils. These injections of water into the superheater tend to bring the temperature of the steam delivered down to normal again, and a red light on the control board indicates that the normalizer is in action.

The action of the normalizer under ordinary conditions maintains a practically constant delivery temperature. If, however, the adjusting orifice valve has been improperly set and the deficiency of water supplied to the boiler is too great, the temperature will continue to rise. As the temperature rises, the temperature fire control contact, which is set at 830 deg. fahr., makes and energizes the oil shunt valve and air-closing solenoids which, respectively, cut the oil and air supplied to the burners in two, the water supply remaining the same. A blue light indicates that the fire has been curtailed, and this is a signal to the fireman to increase slightly the amount of water passed by the adjusting orifice. The correct setting of this value is shown by off and on indications of the red light (normalizer). Off and on indications of the blue light, with steady red light, show a deficiency of boiler feed.

If for any reason the temperature still continues to climb, the maximum-temperature contact of the thermostat, which is set at 840 deg., breaks, and this brings about the complete shutting off of the fuel and the air from the main or running burners, the boiler feed continuing unchanged. A pressure diaphragm provides against undue pressure rise and the breaking of the pressure contact cuts off the main burners, the air and the boiler feed completely, the standby burner, however, together with the standby water regulating valve, still remaining in action. The functioning of the controls constitutes a normal and orderly part of the operation of the boiler. Central station design, too, it should be noted, is exhibiting a marked trend toward automatic control at the present time, supplemented, of course, by manual control.

The feed pump throttle is controlled by the weighted piston of the compensator, and the feed water delivered varies with the amount actually required as determined by the position of the main control lever and the amount of opening of the regulating orifices of the compensator. By this means a constant pressure is maintained at the regulating orifices; hence, the rate of delivery to the boiler is determined solely by the total passage area of these orifices; for, should more water be delivered by the feed pump than the orifices can pass at this constant pressure, the weighted piston rises and the pump throttle is partially or completely closed. The reverse effect opens the pump throttle. The adjusting orifice is installed to provide a measure of adjustment to the compensator valve independent of leverage and linkage. It determines the normal boiler feed deficiency. The settings of the standby orifice and burner are determined by standby needs.

It will be seen that the control system of the locomotive boiler, as designed, calls for manual regulation of the boiler feed. The fireman must adjust his main control lever from time to time to satisfy the fluctuating demand for steam; increasing the supply with falling pressure; decreasing the supply with rising pressure. In the automobile boiler, however, the rate of admission of feed water is controlled automatically by a pressure diaphragm, and the driver of the car is relieved of responsibility for the maintenance of proper boiler pressure.

The tube in which the thermostat element is housed is positioned at the rear of the firebox immediately in front of the first bank of flat coils, although its connection with the superheater section, like that of the normalizer inlet, is some distance ahead of the point of steam delivery, Fig. 36. The thermostat housing is placed within the firebox so that, in the event of the stoppage of steam flow, the heat of the firebox will bring about the shutting down of the fire. The bore of this tube is smaller than the superheater tube, and the velocity of the steam correspondingly increased. This, by augmenting the rapidity of heat transfer, increases the speed of response of the element to temperature change.

Performance

Fig. 38 shows a performance curve for the small boiler developed from four tests, the data of one of which are presented as Table IX. A curve showing the performance of a modern steam generating unit recently installed in the Oakland plant of the Pacific Gas & Electric Co. is included with the Doble curve for comparison. The Oakland unit burns oil and delivers steam at 450 lb. and 725 deg. fahr., the rating being 425,000 lb. per hr. Its air heater is not given effect in the curve. Both curves are referred to total heating surface, including superheat and water walls, the total surface of the Oakland boiler being 35,000 sq. ft. Run No. 16 of Table IX records data for the highest driving rate attained during the Doble test. The boiler operated

DOBLE BOILER—GASOLINE.
OAKLAND BOILER—FUEL OIL.
CURVES ARE REFERRED TO TOTAL HEATING SURFACE.

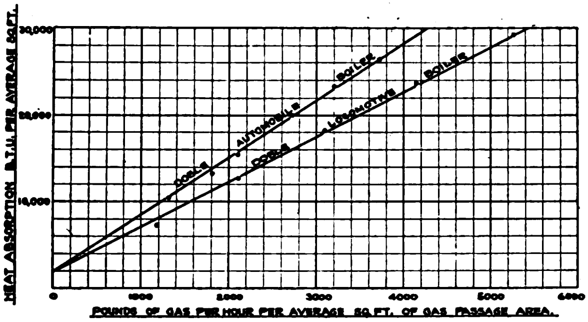

FIG. 39—DOBLE BOILER HEAT ABSORPTION RATES.

during this run at an efficiency of 76.96 per cent, the equivalent evaporation rate being 27.19 lb. per average sq. ft. per hr. This showing is all the more remarkable when it is remembered that the divisor employed to reduce evaporation to a sq. ft. basis is total heating surface and not merely evaporative surface.

Fig. 39 shows the results of the Doble test, Table IX, plotted in conformity with the general boiler heat transfer equation

$$R = a + b\,\frac{W}{A};$$

that is to say, heat absorption in B.t.u. per average sq. ft. of total surface per hr. plotted against lb. of gas per hr. per average sq. ft. of gas passage area. The tendency of the plotted points to range themselves in a straight line cutting the heat absorption axis just above the origin is well illustrated. The results of the several runs, then, exhibit a marked consistency with the experimental showings of boilers of other types. Calculated performance data for the locomotive boiler, based on the assumption that the Doble performance curve of Fig. 38 would hold for the larger generating unit, are presented in Table X, and the locomotive boiler heat absorption curve, plotted from the figures of items (10) and (12) of the table, is included with Fig. 39. The points fall below the Doble curve, and the average line ranged through them is at a lesser inclination, as we should expect; for it is well known that the inclination of such lines varies inversely with the area of the gas passage. The locomotive boiler, with its greater tube diameters, presents wider tube spaces to the flow of the gases.

Summary

It will be seen from the foregoing that the following is true of the Doble boiler:

1. A proportionally large amount of surface is presented to the radiant heat of the fire.
2. Both feed and draft are forced and, therefore, positive; each unit of working fluid in its progress through the tube passes successively over each unit of surface, and violent turbulence due to high velocity is set up alike in fluid and gas.
3. The coils in the convection section are placed across the direction of flow of the gases, and the inter-tube and inter-coil spaces are greatly reduced, while the amount of surface presented to the gases per lineal foot of gas passage is relatively large. With such an arrangement, the hydraulic mean depth of the gas passage is everywhere reduced to a minimum, a condition which, when the velocity of the gas is maintained at a high rate, promotes the rapid mixing of the gas, shortens the travel distance of the hot gas molecules between impacts with the cooler surface and increases the number of impacts per unit of time. The resultant impartation of heat, therefore, takes place at a very high rate.
4. The temperature drop of the gas and the temperature rise of the working fluid are both reasonably uniform from the burner to the stack; and this condition promotes the efficiency of heat transfer.
5. The boiler is essentially safe. There is no great reservoir of stored energy confined within the walls of a barrel of large diameter or compressed between expansive and precariously stayed flat surfaces. The explosion hazard does not exist. The accidental bursting of a tube is no more a serious matter than the blowing of the safety valve; for the sectional area of the escaping steam in either case is about the same.
6. The response of the boiler to widely and rapidly fluctuating demands for steam is practically instantaneous, and this rapidity of response does not depend upon the impounding of great reserves of heat within the unit itself, but rather upon the known ability of generators of the single tube type to convert the potential energy in the fuel instantly into steam as required.

In other words, the Doble boiler is a serviceable heat absorber of great efficiency because it combines to the very highest degree those elements of design which, in the light of our present knowledge of the phenomena of heat transfer, are known to augment the rapidity and efficiency of heat absorption.

Summary of Doble Laboratory Test No. 186

Standard Doble automobile boiler tested. Length of tube, 558.5 ft., of which 120 ft. forms the helical coil surrounding the firebox. Effective heating surface (measured outside the tube), 80.4 sq. ft., of which 10 sq. ft. was exposed in the firebox. Heating surface in the firebox is computed by multiplying the tube length by the outside tube diameter and the factor 1.4. Furnace volume, approximately 2.5 cu. ft. Fuel, gasoline; forced draft. Feed water 74 deg. fahr. Steam delivered at 850 deg. fahr.

Results of the test are shown in Table IX.

Summary of Calculated Boiler Performance Data
Doble Class D-1 and D-2 Locomotive Boiler
(Compiled from the locomotive report of Feb. 29, 1928)

Length of tube, 3838.2 ft., of which 1233.9 ft. form the water-cooled lining of the firebox. Effective heating surface, 3044.1 sq. ft., of which 700.9 sq. ft. are exposed to direct radiation in the firebox. Furnace volume, 831.5 cu. ft. Fuel, oil, mechanically atomized; forced draft with air preheated to 400 deg. fahr. 20 per cent excess, the air being heated by the flue gas. Feed water, 300 deg. fahr. Steam delivered at 800 deg. fahr. and 1500 lb. per sq. in., absolute.

Results of the tests are shown in Table X.

FOREIGN DEVELOPMENTS

Abstract

This Serial Report contains some interesting statements by American engineers, among them Messrs. I. E. Moultrop, A. D. Bailey and G. A. Orrok. Several foreign engineers have contributed some general statements, including Messrs. F. H. Rosencrants, W. H. Patchell, A. L. Mellanby, J. Mas Nieto and R. H. Andrews. A number of other prominent European engineers have submitted statements covering some detailed engineering developments. Some abstracts from foreign journals are also included. The opinions expressed in these statements are quite specific and indicate the general trend of power plant development in foreign countries.

Summary of European Development in Power Generation

STATEMENT BY I. E. MOULTROP, BOSTON, MASS.

Higher Steam Pressures and Temperatures

European engineers have gone farther in elevated steam temperatures than we have and they appear to be more interested in this step than in higher pressures. There are several installations operating or under way, with temperatures ranging from 800 to 840 deg. fahr., and the ones in operation seem to be reasonably free from troubles due to temperature. At Langerbrugge, and at one or two other places, they have standardized on carbon steel superheater tubes which are reasonably reliable for the above-named temperatures, but it is generally believed that the safe limit has been reached. Much study and research are going on to develop a commercial material which will be good for still higher temperatures.

They do not seem to be as much interested as we are in higher pressures. A small installation at the municipal plant at Bradford is designed ultimately to operate at 1100 lb., but the initial operation will be at 800 lb. The Imperial Chemical Company is building a plant near North Tees which will ultimately have a capacity of 100,000 kw. where the pressure will be 800 lb. and the temperature 840 deg. fahr. This is the largest high pressure installation of which I have any knowledge in Europe. These steam conditions were chosen because of need in their synthetic ammonia plant for a very large amount of process steam at a certain pressure and temperature, and they are superimposing a power plant on top of their process work.

The other notable development in high pressure is the Benson boiler as built by the Siemens-Schuckert Company in Berlin. They have taken the Benson ideas and developed a fair sized boiler which they had installed at their works in Siemenstadt some time ago, for the purpose of experimentation. I was advised that this boiler furnished the necessary power to operate their cable works for a month or two last winter while they were altering the works' power house. When this boiler was first promoted, the idea was to generate at the critical pressure of 3200 lb. and then reduce the pressure one-half for utilization in a prime mover. They now think that it is not necessary to cut the pressure in two as they can get prime movers that will work with pressures running from 2000 to 2500 lb. Of course, if this can be done, it makes this scheme somewhat more attractive. I am, however, not yet convinced that the Benson scheme has any advantage over the 1200 lb. development on this side, and during the long interview that I had with Dr. Gleichman, who is in charge of this development for Siemens-Schuckert, he could not show me where this system had any advantage in efficiency over ours, but he did think that the first cost was lower. This may be true, for apparently the Benson boiler can be constructed to be installed in the open which is a distinct saving of installation cost. He thought the boiler could be built cheaper as it has no large steam drum. I think there may be a little saving here, but it will not be as much as the Germans anticipate, because their experimental boiler was built of very light material and would not meet the requirements for American service.

I found with a great deal of interest that the Germans are producing boiler drums without riveted seams. They are turning out a great many welded drums, mainly forged welded. European steel interests are also giving some thought to drums forged from the ingots with no welds. One large manufacturer in England is building a forging plant to turn out solid drawn drums. They expect to produce drums at a cost very close to that of the riveted drum. If possible this will materially reduce the cost of building a high-pressure boiler along conventional designs.

Turbine Design

There seems to be little new in turbine design abroad. So far, the manufacturers have not been called upon to build very large units, and, therefore, have not run into the troublesome problems that we have encountered here on the extreme sizes, but they are all giving much attention to refinements of design. They seem to be having some of the bucket troubles which we have experienced and are searching for more suitable material for buckets. They are solving the troubles at the entrance edge of the bucket by making this edge blunt and rounded like the front edge of an airplane wing instead of a knife edge which promises to give much longer life. Buckets are subject to very fine tests after fabrication to detect cracks. Standard size units abroad seem to be about 20,000 kw. Much attention is given to efficiency which is equal to or a little better than what we are obtaining. There is no doubt but what they get better materials, their foundry work is better, and I am inclined to think that their machine shop work is equal to or a little better than on this side.

Boiler Design

It is surprising the number of different boiler designs one finds in Europe. One might say that the B. & W. is still the standard design. Outside of the Benson boiler the most striking design I think is the Loffler. Many are practically a modification of the Stirling type and others are hard to describe. Apparently they are searching for better efficiency, and out of the multitude of different designs something may be brought out which will be a distinct improvement, but it will take time to prove this.

Processing of Coal

There is quite a bit of discussion on the processing of coal in Europe. Many schemes are being advocated, but I failed to find anything of real value to the power plant engineer in the United States. As I see the situation, the whole idea depends on the by-products and their market value. With the ordinary by-products taken at their present market value, there may be a little gain by some of the carbonizing systems, but one must not forget that in any of these carbonizing systems from 20 to 25 per cent of the heat value of the coal is lost. This is quite a handicap to start with, and the market value of the by-products does not have to drop very much before the enterprise would cease to be profitable.

Publication No. 289-64, Serial Report, Prime Movers Committee.

Thermal Storage

Thermal storage seems to be getting a new lease of life in Europe, and a scheme has been developed whereby the storage energy is utilized in a special turbine of cheap construction which will operate on varying pressures down to within a few pounds of atmosphere. This seems to have some merit for certain conditions. I am advised that one continental utility is giving serious consideration to installing this system in a plant it is about to build. (This plant is now under construction at Charlottenburg.—Editor)

Fuel Burning

Following the development of powdered coal in the United States the idea appears to have been taken up enthusiastically abroad, and quite a number of powdered coal installations have been made during the past few years. This is natural when you consider their chief stokers were of the chain grate type which had decided limitations. I was surprised, however, to find a decided trend back toward the stoker. The American type of underfed stoker is being introduced and seems to be meeting with favor. Several of the latest stations to be built are equipped with stokers. It was interesting to find two new steam plants in Italy, the one country in the world where water power has been universally used up to now and where there is no coal. Until recently there were practically no steam plants in Italy, but both the Milan Edison Company and the Lombardi Company, which, between them, practically cover Italy, have found a steam stand-by a necessity with water power. The Milan Company has built a station at Genoa which is worth one's time to visit, and the Lombardi Company has built a plant near Turin. Coal from England will be burned on stokers.

The most notable power plant east of the Atlantic is the Klingenberg Station in Berlin. In my opinion, this station compares with anything in the United States, both in design and in efficiency. The cost of this station is remarkably low, something like $60 per kw. It is a remarkable station also because it was designed and built in about a year.

European Observations

STATEMENT BY ALEX. D. BAILEY, COMMONWEALTH EDISON CO., CHICAGO, ILL.

As one travels through a foreign country rather hurriedly and attempts to see as much as possible in a given time, he is able to form only general impressions, and detailed study of particular points must be left for more deliberate inspection. We know from our own experience that everyone is on his best behavior when visitors are around and the family skeletons are securely locked in the family closets. First impressions are quickly made and if we had been able to stay longer and had been able to study conditions more closely, some of these might have been altered.

Station Design and Operation

With a few exceptions, European stations generally evidence the necessity for the strictest economy, particularly in the construction of station buildings. The architectural features are generally missing. On the other hand, the Klingenberg Station, in Berlin, is probably one of the finest examples of architectural design which one could find. From a technical standpoint as well, this station is very impressive.

The water power stations of the Italian Edison Company in the northern part of Italy are wonderful examples of architecture, both in design and in the beauty of their finish externally and internally. With the investment costs as high as they must necessarily be, because of natural conditions, one wonders how this additional expense can be justified.

Both turbine and boiler units are generally smaller than in America. The largest boiler installation in Europe we were told has a maximum capacity of 300,000 lb. of steam per hour, and boilers of over half this capacity are exceptional.

The development of transmission systems is growing and spreading very rapidly, and new stations of large capacity are being planned which will compare favorably with installations in this country.

Investment costs are, of course, much lower than in this country, and when to this is added the economical construction of buildings, the resulting costs are quite surprisingly low, about sixty per cent of American costs, or possibly less.

Most of the stations which we saw are operating on load factors which we would consider very low, and in addition they carry an unusually high percentage of reserve capacity. Station outputs are correspondingly low. The largest single station output in Great Britain for last year was three hundred and twenty-five million kw-hr., and only two others were above three hundred million kw-hr.; six more had an output of over two hundred million. On the continent some of the largest stations have an output considerably in excess of this figure, but the output is invariably low when compared with the capacity installed.

In the operation of their stations it is quite apparent that they are subject to about the same kind of troubles which we encounter here, and that they are faced with about the same problems as those to which we are accustomed.

Although manufacturers and operators were loath to admit or discuss troubles with their equipment, it is quite evident that human nature and machinery are very much the same in Europe as in America, and that they are both subject to the same ills.

Higher Steam Pressures and Temperatures

Whether European engineers are more daring than their American friends may be open to question, but it is a fact that several plants, both in Great Britain and on the continent, report that they have been operating for considerable periods with steam temperatures of 800 deg. fahr., or even higher, and that super-heating equipment, piping and turbines have stood up successfully under these temperatures. Many of the newer stations being planned will operate at steam temperatures from 800 to 850 deg. fahr., and most of the turbine manufacturers seem to be ready to build turbines for this service. They all say that high steam temperatures are entirely a matter of superheater operation.

In the matter of higher steam pressures, there is an 1100 lb. installation at Bradford, England, although the turbine is quite small. This exhausts into steam headers in the older part of the station, which operate at 200 lb. A larger unit is being planned for the same station.

On the continent several turbine manufacturers state that they have built, or are building, small turbine sets for extra high pressure, in the neighborhood of 100 ats. (1420 lb.). None of them carry the steam through the entire expansion, but are super-imposed on an existing steam system or the steam is exhausted at some fairly high pressure, and used for industrial purposes.

The Benson boiler and turbine at the Siemens-Schuckert Works, in Berlin, are in continuous operation, and a new boiler installation with the same operating pressure, but somewhat different in design, is being planned by the manufacturer.

So far as turbines are concerned, the general trend of European turbine design is favorable to higher temperatures, as turbine wheels are generally small and material stresses are correspondingly reduced.

Pulverized Fuel

The application of pulverized fuel is spreading rapidly, not so much because of the increase in the size of the boiler units, as because everyone expects to burn low grade fuel at high efficiency.

The development of this method of firing seems to be at the "optimistic" stage. Reports of the success of American installations have given it a great impetus. There were the usual discussions regarding Bin Systems vs. Direct Firing, and the exponent of each system quotes from American practice those points which will best serve his purpose. Very few have seriously attempted to catch the dust in the flue gas, and if they did catch it no one seems to know of a satisfactory means of disposal. This phase of the pulverized fuel problem has not been given as much study as it demands if this method of firing is to become more universal. So far the subject is dismissed by saying it is not yet a problem and that it can be easily taken care of whenever it becomes necessary to abate the nuisance.

The Germans and Czechs report that they can successfully burn pulverized brown coal, which has over 50 per cent moisture as mined. The Russians are experimenting with pulverized anthracite culm, brown coal and oil shale, and though they have only small installations in service now, they are planning a great expansion of this capacity in the next three years.

Coal Carbonization

Judging from the papers presented at the Fuel Conference, and the discussion which followed, there is the greatest interest in this subject, both in Great Britain and on the continent. It was quite surprising to know how many processes and projects are being tried, although none of them apparently have been commercially successful, or would be on a large scale. Most of the installations are of an experimental nature and size. It was reported that in England there were some sixteen processes being tried with installations having a capacity of over ten tons of coal per day. It is hoped, of course, that by some such means, the low grade fuels, which are at present sold below mine cost, can be utilized, and that in addition to the by-products, a smokeless fuel can be produced for the thousands of open grates which are in general use.

In Germany they are attempting to carbonize their low grade brown coal, not alone to produce a suitable fuel, but also to reclaim the by-products. In general it is hoped that this method of coal utilization will develop a source of supply of motor spirits and oils, which must now be imported due to lack of natural resources. Everyone is also mindful of the repeated warnings of the limited supply of oil all over the world.

The economics of coal carbonization were quite generally discussed, and the importance of the fixed capital charges was very properly emphasized. It was brought out in the discussion that even though a market might be found for the various products, the success or failure of this method of coal treatment would depend primarily on the cost of the installation.

Power Situation in Europe

STATEMENT BY GEO. A. ORROK, CONSULTING ENGINEER, NEW YORK, N. Y.

In the field of power generation in Europe the past year was marked by a significant improvement in the volume of energy generated, in the provisions for the future, and in the methods leading toward higher economy. Furthermore, the tangible results in economy obtained by the combined efforts of engineers and financial administrators has resulted in a certain stabilization of technical ideas, not without the cooling of certain enthusiasms.

Just as the many countries of Europe have been consolidating their financial position, stabilizing their currencies, readjusting their many channels of trade, so the power people have shaken off the inertia of financial conservatism, and on the other extreme have avoided overreaching the mark by adapting experimental designs before development work had been complete. From the maze of highly technical attempts to save heat units the industry is devoting itself to making and selling kilowatt hours. In spite of the low load factors, the old moderate pressure stations have improved their heat rates and it is quite surprising to see what could be done by the organization of combustion control and by proper load distribution.

One large concern in southern France, which operates a system of steam and water power stations, succeeded in associating the technical and financial cooperation of its large consumers and now the production of the latter is subject to the orders of the central load dispatcher. Another such concern in eastern France succeeded in linking the metallurgical and mining industry with their power plants to such an extent that blast furnace gas engines, waste heat steam plants, water power, and gas engine plants, are working as constituent units in a complex power generating system controlled by the central load dispatcher according to a plan of annual production. Apart from the technical difficulties of linking such different sources of power, these feats reflect highly on the financial sagacity and cooperation of the responsible administrations. Of course, the economic gains from such reorganizations are far greater than from any technical improvements. France is looking far into the future and her development of water power with special aid from the government is at present well ahead of what the economic conditions of the year would warrant.

Director Rehmer of the Berliner Städtische Electrizitäts Werke has published a plan of the future extensions of the Berlin system calculated for ten years ahead. The significance of such plans on a national scale for the better development of industry is patent. The long distance transmission lines in Germany have gradually reached the point in development in which the water power of the South, the bituminous coal of the West and the brown coal of Mid-Germany is being utilized to the best advantage. Of course, the fluctuating coal prices will be taken care of by the load distribution as well as the peak power demands. With the thoroughness peculiar to the Germans, many smaller concerns seek to utilize the local economic differentials even on slim margins by installing power plants of the mixed type, special peak load units, steam and hydro accumulator stations. But as a firm ground for the better future is seen the unceasing effort of improving the operating conditions, particularly combustion, in the existing plants.

The export and import of power between the countries exceeded that of the previous year. The greatest possibilities of improving the performance of old plants is in England, and the efforts of the Electricity Commissioners will be watched with great interest. The development will begin, probably by a wholesale shut down of the smaller plants and proper loading of the larger ones. The short transmission distances favor the construction of super stations, the program of which is under study.

Probably there is no other country where the utilization of the major water power source is pushed to such an extent as Italy. There we can see the steam plants as well as the majority of water storage plants, built to increase the total output from the costly hydroelectric developments. Some of their steam peak load stations present the finest examples of the sound blending of economical and technical principles in designing a station for the specific conditions.

In Belgium, Czechoslovakia and Holland, where the individual electrical outputs of the stations are small, we see the boldest steps taken to secure thermal economy. The Langerbrugge and the Witkowitz stations are operating at 850 and 930 deg. fahr. steam temperatures; the Merwede Canal station and the Maurits station represent the highest and most complete technical developments for a small station. It is interesting to note that parts for these stations were purchased from England, Germany, Switzerland, France and the United States, besides those which were made at home.

The purely technical situation as concerns the steam stations presents three main items of interest. First, the reduction in cost of the high pressure equipment which goes hand in hand with the acquired experience, increased volume of orders and reduction in the number of paths for development. Second, the fractionation of fuels, peculiar to European countries where the shortage of native liquid fuel, smoke nuisance, the short hauls and the ability to get along with low capital returns favors the different ways of processing the raw coals. Third, due to the increased size of their power plants the European engineers are realizing the economics coincident with the larger sized machinery and the size of their units are steadily increasing. Not a small part of this must be attributed to their annual visits to this country, where they become familiar with machinery on a much larger scale.

Concerning the water power situation, we can notice a sustained interest in the low head developments, the better sites being already developed. Tidal power in England is quite likely to soon become an accomplished fact.

Notwithstanding the increasing number of powdered coal installations it appears that a reaction toward stoker firing has set in. The quiescent status of the stoker business has been changed and the current year probably will see a great revival in its use which in Europe has lagged far behind its American contemporaries. The return to stoker firing in Europe is perhaps connected with the flying ash nuisance and the strict smoke ordinances vigorously enforced. The attempts to obtain complete ash precipitation have not been successful. The unwieldy European stokers have given way to more flexible designs and together with the water cooled furnace walls the flexibility of firing inherent to the powdered coal will be attained with stoker firing even for the most difficult classes of European coals.

STATEMENT BY F. H. ROSENCRANTS, INTERNATIONAL COMBUSTION, LIMITED, LONDON, ENGLAND

This company states, with considerable gratification, that in comparison with previous years' reports, in which new forms of equipment were described, there have been few changes made in the past year. This applies specifically to the activities of the firm with which the writer is officially associated and also generally to England as a whole, in so far as information is available. We are content with the fundamental design of equipment now in use.

The argument as between direct firing and the bin and feeder system remains unsettled, though at the moment those in favor of the former system will probably outvote the latter, those favoring it preferring to accept its hazards and disadvantages rather than the complications represented by existing installations of the other system. In this the writer observes a consistency with the growing sentiment for simplicity in design, construction, and operation as applying to steam electric generating stations. In the bin and feeder system we have unquestionably reached, and are now receding from, a pinnacle of complications. Driers as such are rapidly ceasing to be considered an essential part of a pulverized fuel fired system, the scheme of drying in the pulverizer circuit with highly preheated air having rapidly taken its place.

Vents to the atmosphere with their consequent dust nuisance have ceased to exist on new installations. The close association of the pulverizing units with the boilers which they serve is eliminating the need of elaborate transport equipment, which has been reduced to that required for transferring fuel from a given mill to adjacent boilers, operated only in emergency. Normally each boiler is supplied by its own mill direct to the storage bin. The capacity of the storage bin may be and is being reduced to only a few hours' supply with a consequent saving in space and first cost, but with the advantage of retaining the superior control and reliability incidental to the bin and feeder system.

The item now receiving the greatest attention is the further development of dust elimination from flue gases. To date this problem has been attacked through the medium of centrifugal devices and by water washing. Electric precipitation, while the subject of some discussion, has thus far made no progress in England, owing primarily no doubt to its first cost. In many instances, centrifugal dust separation in its best developed form will constitute a sufficient remedy, since by such means the most objectionable coarse material is completely removed, though the color of the issuing gases is but little cleared. In the congested districts, however, something more effective will doubtless be demanded. At the moment, developments in the water washing scheme appear most promising. Several installations designed as an afterthought and applied under unfavorable conditions are in operation, but are giving results which are most encouraging and point the way to further progress in the development of designs which, being foreseen, may be installed under favorable circumstances. Better results, therefore, may be anticipated.

The necessity and desirability of water cooling the furnace walls has been universally recognized by all suppliers of equipment, and there is a rapidly growing tendency to incorporate such walls as an integral part of the boiler, whereas in the past such walls were a growth upon the conventional design of the boiler unit. In nearly every instance existing installations with their multiplicity of downcomer water pipes, riser steam pipes, external circulating tubes, etc., have every appearance of being an afterthought. Persistency, however, in retaining the individuality of the furnace cooling system independent from the boiler unit seems, to the writer, too ridiculous to contemplate. He is sure that while past efforts in this direction may leave something to be desired, such efforts are a step in the right direction and will prove forerunners of what will ultimately become established practice. So far as England is concerned, several contracts have been placed recently for such units, and a good many more are anticipated prior to the publication of this data. The adoption of such units is resulting in more or less drastic modification in arrangement of equipment, with saving in first cost and simplification in design, construction and operation, with consequent greater reliability and less anticipated maintenance. At the moment, details of these designs are not available for publication.

Trends in European Power Development

STATEMENT BY DR. A. L. MELLANBY, ROYAL TECHNICAL COLLEGE, GLASGOW

In reviewing developments during the past year in Great Britain and on the Continent, the most noticeable changes are in the two branches of engineering usually considered to be the most conservative—those of marine and locomotive engineering. In the marine world the reaction to the success of the Diesel engine is now taking effect, and shipowners and superintendents are prepared to take risks which a few years ago they refused to face, in order to obtain that increased economy which steam engines and boilers are still capable of giving. The locomotive world has also seen remarkable departures from the almost reverenced type of steam engine, and internal combustion units, together with special types of steam engines and boilers, have been tried with encouraging results. Confidence in the use of very high pressures is most evident on the Continent, and several novel designs of locomotives have been put into service using pressures and temperatures that a comparatively few years ago would have been regarded as impracticable.

Central Station Practice

The tendency to use very high pressures in central station practice is no longer so evident, and the more recent of the larger plants are being designed for moderate pressure. This is probably due to the careful study that has been given during the last few years to thermodynamic problems associated with the boiler and engine room. Dealing with ideal engines only, it is easy to show that increased economy is intimately associated with constantly increasing pressures. But when the losses which must inevitably accompany the very high pressures are taken into account, the promised economy is not so evident. The gains to be expected from pressures beyond 1000 lb. per sq. in. are very small indeed. In Britain, where at present capital outlay has to be closely watched, very careful attention has been given to the first costs of high pressure plants as well as to the diminished fuel consumption that might be anticipated. With coal at its present moderate price, and with load factors much below those common in America, the actual economic gain to be obtained from very high pressures presents no attraction when the present cost of plant is taken into account.

British Examples

This policy is reflected in the new boiler installation for the Clyde's Mill Power Station of the Clyde Valley Electrical Power Co. Four Babcock and Wilcox cross-drum boilers will be installed. Each boiler is provided with a steel tube economizer and a tubular air heater, and at its normal rating will provide 87,500 lb. of steam per hour with a maximum rating of 116,000 lb. per hour for two or three hours. The working pressure will be 400 lb. per sq. in. with a temperature of 750 deg. Fahr. Chain grate stokers will be fitted and the preheating will raise the temperature of the admission air to 225 deg. Fahr.

A further illustration is afforded by the recent extension to the Barton Power Station of the Manchester Corporation. This station was opened in 1923, and since then has been noted for its low fuel costs and high thermal efficiency. The latest returns indicate that during last year the average coal consumption was 1.39 lb. per kw-hr. generated, and the thermal efficiency was 21 per cent. Three additional Babcock & Wilcox marine type boilers were installed, two of which are fired by chain grate stokers and the other by pulverized coal. Each of the stoker-fired boilers is capable of producing 150,000 lb. of steam per hour and the pulverized fuel boiler 170,000 lb. at 375 lb. per sq. in. and 750 deg. Fahr. The new generating set will develop 40,000 kw. and is of the tandem impulse type, with 24 stages in the high pressure and 16 stages in the low pressure cylinder.

A Continental Example

The Klingenberg station of the City of Berlin Electricity Co. illustrates the latest continental practice. Sixteen boilers operate at 500 lb. per sq. in. and 770 deg. Fahr. with a maximum rating of each boiler of 160,000 lb. of steam per hour. All boilers are fired with pulverized coal. Each pair of boilers is served by a steel chimney 230 ft. high. The turbo-generators, three in number, have each a maximum rated capacity of 80,000 kw. and are the largest units running in Europe at the present time.

Super-Pressure Plants

The only example in Britain of very high pressure units is at Bradford, where a new high pressure turbine, designed to take steam at 1100 lb. per sq. in. and 800 deg. Fahr. has been added to the old installation. The exhaust from the new turbine is led to the existing steam main pipe and from there passes to the older turbo-generator sets.

A boiler for pressures of the order of 1600 lb. per sq. in. has been constructed by Messrs. Sulzer Bros. at Winterthur, which may briefly be summarized as a combination of a low-pressure boiler acting as a feed water heater auxiliary to a high-pressure boiler where all the high temperature heat transfer takes place.

In the Loffler boiler the whole of the high temperature heat transfer is to the high pressure steam through the superheater tubes. The superheated steam so produced is partly used for outside consumption, but the greater portion passes into a drum, where it evaporates feed water as saturated steam which is, in its turn, superheated and the cycle repeated. Several boilers of this type operating at 1700 lb. per sq. in. and 900 deg. Fahr. are in service.

A number of boilers on the Atmos principle, where steam is generated in revolving tubes, have been installed in Sweden and in Germany. These boilers operate at a pressure of 1500 lb. per sq. in. and are stated to be working satisfactorily with absence of trouble from the rotating elements.

STATEMENT BY W. H. PATCHELL, CONSULTING ENGINEER, LONDON, ENGLAND

The Annual Report of the Electricity Commissioners for Great Britain for the year ending March 31 is only published late in December, so that the Report for 1927-28 is not yet available.

The Grid

The 1926-27 Report records progress in the development of schemes by the Central Electricity Board, which have been prepared and transmitted to them by the electricity commissioners.

Under such schemes the Board is constituted the central supply authority from whom authorized undertakers will generally obtain their supplies of electricity in bulk. The distribution of the supply and the commercial development of electricity is left in the hands of the undertakers, as previously.

Such schemes determine what generating stations, existing or new, are to operate as "selected" stations and provide for their interconnection by main transmission lines, either existing or to be constructed by the Board.

The principal main transmission lines will be three-phase overhead, operated at 132,000 volts between phases, with a capacity of 50,000 kw. The secondary main transmission lines will be for 33,000 volts or other approved voltage. The commissioners have based their estimates for the London district on three phase 22,000 volt cables, but are carefully watching the result of operating the 66,000 volt cables in Paris, and of the 132,000 volt cables at Chicago and elsewhere, hoping that the experience gained before the Board must issue its specification, will enable a higher voltage to be adopted without undue risk.

A model of the principal transmission towers was lately shown, and they were described as approximately 80 ft. 0 in. high, 16 ft. 0 in. sq. at the base. The conductors will be placed 12 ft. 0 in. apart vertically and will, for the Central Scottish scheme, be steel cored aluminum cable with a diameter of 0.77 in., equivalent to copper of 0.157 sq. in. section.

The schemes cover areas of the country in appropriate regions so that work may be begun in such areas in such a manner that they will eventually form a coordinated whole.

Up to date, schemes have been put in operation for the industrial regions of central Scotland and for southeast England. Several joint electricity authorities have also been formed who later on may be included in schemes for the areas in which they are situated. The vista looms heavy with questions of over-lapping and load dispatching. Schemes have also been published, but are not yet adopted for the northwest midland district and central England. Such is the "Grid."

Power Station Economy

The returns of fuel consumption and kilowatt-hour generated made by the electricity commissioners for the year ending March 31, 1928, was published in October, 1928.

Such returns are in respect to 570 generating stations, which is the same number as in the previous year.

The total number of kilowatt-hours generated was 9,927,850,630, an increase of 18.7 per cent over the previous year.

The total coal, coke, and fuel oil consumed was 9,224,151 tons, or an increase of 4.1 per cent.

The lowest fuel consumptions recorded among the steam stations are:

Name of Station	Kw-hr. Generated	Load Factor, Per Cent	FuelConsumption Lb. per Kw-hr.	Thermal Effy, Per Cent
Padihan (The Lancs Pr. Co.)...	45,176,309	36.2	1.37	21.03
Barton (Manchester Corp.)....	325,427,230	51.2	1.39	21.07
North Tees (Newcastle-on-Tyne Co.)................	249,374,810	47.3	1.39	20.49
The best internal combustion engine station are:				
Oil (Bognor)................	854,886	20.1	0.62	28.23
Producer Gas (Thirsk)........	495,959	30.0	1.45	16.60

The average fuel consumption converted to the basis of coal over all the stations is:

Steam Stations ..... 2.16 lb. per kw-hr. generated
Oil Engines .... 0.91 lb. per kw-hr. generated
Gas Producers ..... 2.24 lb. per kw-hr. generated

The steam conditions obtaining at the first three stations are interesting, and show what can be done with a moderate pressure and temperature:

Padiham......Lb. per sq. in. gage 250; temp. deg. Fahr. 620
Barton........Lb. per sq. in. gage 370; temp. deg. Fahr. 677
North Tees....Lb. per sq. in. gage 450; temp. deg. Fahr. 650

While North Tees had reheat in the earlier plant, it has not been included in the extensions.

Among novelties in new plants, a 40,000 kw., single spindle, 2 cylinder, 1500 r.p.m. turbo alternator has just been started at the Barton station.

The 1200-lb. set at Bradford has been delayed by building operations. This is the only example of compounding a station since Langerbrugge in Belgium, where the first 800-lb. boiler with a 2000 kw., 710 lb. gage pressures, 828 deg. Fahr. machine was started in 1925. They now have another 6000-kw. set also for "compounding," and have ordered a three-cylinder 20/25,000 kw., 3000 r.p.m. machine to run condensing.

Steam pressures are increasing. Several plants lately ordered on the Continent are to operate at 500-600 lb. The I. C. I. have had a 600 lb. plant at work for some time at Runcorn; their 800 lb. plant ordered for Billingham is just being started.

The last order for Yallourn, Melbourne, which plant started with 270 lb. pressure, is for 650 lb.

The London Power Company is putting in 600 lb. for the new station at Battersea, and has just ordered for it two 67,250 kw. turbo-generators to operate at 570 lb. per sq. in. gage pressure and total temperature of 850 deg. Fahr., with a feed heating system by bleeding.

The boiler position is interesting. Steel manufacturers are now supplying hollow forged steel drums 50 ft. 10 in. long, 4 ft. 6 in. internal diameter, with a finished wall thickness of 4½ in. On the Continent, gas welding has made great advances. About 700 welded drums were supplied up to the end of 1927, including 39 for the Rummelsburg station, Berlin, and are working satisfactorily at 525 lb. steam pressure.

A huge hydraulic press, which will bend plates 40 ft. 0 in. in length, 2¼ in. in thickness, to a three-quarter circle of 4 ft. 6 in. in diameter, has lately been put to work.

British insurance companies now accept welding for steam pipes and valves of large dimensions, and in view of the experience with welded drums on the Continent, may soon be induced to accept welded drums as commercial risks and put an end to the present anomaly. It may also have a steadying effect on the present rapid rise in prices when the boiler pressure exceeds 400 lb. per sq. in.

The question of dust from pulverized fuel fired boilers is not yet settled. Hackney, which is a "selected" station for London, has abandoned its pulverized fuel plant as unsuitable for London conditions.

The London Power Company are adopting stokers for Battersea. Berlin has pulverized fuel at Klingenburg and is adopting stokers for its new station, which is in a better residential quarter. Meantime, Derby is increasing its pulverized fuel installation.

The Fuel Conference in September brought up the combination of low temperature carbonization and steam raising, but so far Dunston was the only installation described at the Conference, though there are rumors of the next Newcastle installation being on the same system.

Combustion in Spain

STATEMENT BY J. MAS NIETO, CONSULTING ENGINEER, BARCELONA, SPAIN

Up to the present the combustion of coal in Spain for the purpose of producing steam has not made much progress. There are few plants that we may call modern steam plants. What we term modern plants in Spain consist merely in the use of water tube boilers, most of them of the Babcock & Wilcox type, which are now manufactured here.

In the industrial districts water is generally very hard and only now the use of water softeners has become popular. This, of course, has contributed to the use of old types of boilers with a very low efficiency.

Due to the fact that Spain has important coal sources of middle and low qualities, the combustion in pulverized form will become very important in the near future. At present very few plants of this kind are installed. Some successful tests have been made in cement kilns, and a very few trials have been carried out in steam plants. The most modern of its kind was recently adopted by "Cooperativa de Fluido Electrico" for their steam reserve plant. This plant is situated in the Pyrenees Mountains, close to the coal mines. It consists of three Garbe boilers, of 590 sq. m. (6350 sq. ft.) heating surface each, to work at 16 kilos per sq. cm. (227.5 lb. per sq. in) pressure, at a temperature of about 375 deg. Cent. (700 deg. Fahr.)

The pulverizing plant contains a raw coal bunker of 100 tons capacity. Coal is thence conveyed to rotary dryers and stored in two bunkers of 40 tons capacity each. There are two pulverizing mills of the "Hardinge" type with the necessary separators, fans and cyclone. Coal bins of 25 tons capacity each have been installed in front of each boiler. Burners, feeders, fans, exhausters, combustion chambers, water tube walls, etc., are of the "Lopulco" type. Air heaters and "Green's" economizers, together with an hydraulic system of ash removal, are also installed.

The following results have been anticipated at normal load with coal having a maximum of 7 per cent volatile matter and 40 per cent ash.

Boiler plant efficiency	81.5 per cent
CO_2 at base of chimney	12.5 per cent

As Spain is a very mountainous country, it is also very rich in hydraulic power, which is now having its maximum development. Electrification is rapidly gaining ground and railways are now electrifying their lines. It is hoped that in a few years' time almost all the railways will be electrified. This will necessarily call for important and modern steam reserve power plants.

Engineers will be interested in the International Exhibition at Barcelona, Spain, in 1929. Special electrical features will be displayed in grounds and buildings. Eleven palaces will be devoted to exhibits of industrial and engineering developments. Many international congresses will be held during the exhibition. The whole enterprise has been executed on an elaborate scale and will well repay a visit.

Recent Developments in French Central-Practice

STATEMENT BY R. H. ANDREWS, CONSULTING ENGINEER, PARIS, FRANCE

From the standpoint of heat-power engineering, the most important regions in France are the industrial districts surrounding the city of Paris and the different coal-mining districts, mainly in the north and east.

The power needs of the Parisian zone are at present sup-

TABLE I

ELECTRICAL SUPPLY OF PARIS AND SURROUNDINGS

Central Station	Operating Company	Capacity, Kw.		Steam Conditions	
		Present	Ultimate	Press., Lb. per Sq. In.	Temp., Deg. F.
Gennevilliers...	Union d'Electricite...	340,000	....	320 400	625 750
Vitry II.......	Union d'Electricite...	80,000	....	280	700
Vitry II........	Union d'Electricite...	....	400,000	550	850
St. Ouen.......	Cie. Parisienne de Distribution d'Elec.	325,000	....	280	750
Issy-les-Mouli-neaux........	Cie. Parisienne de Distribution d'Elec.	118,000	175,000	220 625	750 850
St. Denis.......	Soc. d'Electricite de Paris..............	170,000	....	240	600
Ivry...........	Soc. d'Electricite de Paris.............	60,000	200,000	310	700

plied mainly by six major generating stations, operated by three companies. A seventh plant is under construction at Vitry. The characteristics of these stations are outlined in Table I. All will soon be interconnected with the various water-power centers through the French "super-power" network now under construction.

The power needs of the coal-mining centers are principally supplied by mine-mouth steam plants interconnected with water-power stations.

Pulverized Coal Versus Stoker Firing

The respective fields of pulverized coal and of stoker firing are still indeterminate in France. As compared to American conditions, pulverized coal is under considerable handicap in this country, owing to the extreme hardness and the abrasive nature of French coals, which raise the up-keep of pulverizing equipment to several times the figures current in the United States. In the vicinity of Paris, this handicap is further increased by the unsatisfactory load factor of the central stations, which materially reduces the returns on the extra investment required for pulverized coal as compared to stokers.

In spite of this double disadvantage, "Union d'Electricite," after four years of comparative operation with stokers and with pulverized coal, in central stations aggregating over 400,000 kw., has adopted pulverized coal firing for the new station at Vitry, designed for an ultimate capacity of 400,000 kw. The reasons given for this choice are:

1. The excessive variations in the coal supply, which lower the efficiency of stoker firing and cause endless operating trouble. The coal supply is subject, without warning, to fluctuations from 32 to 9 per cent in the volatile content, and of the same order in the ash content.
2. Greater flexibility in following load fluctuations, which in Paris stations are particularly sudden and unexpected.
3. Labor saving in operation and maintenance of the boiler plant.

"Compagnie Parisienne de Distribution d'Electricite" has not yet started experimental operation with pulverized coal. A 57,000 kw. extension to their Issy-les-Moulineaux station, fired with pulverized coal, will be started up in a few weeks.

"Societe d'Electricite de Paris" has been experimenting with pulverized coal for about ten months, with eight 14,000-sq. ft. boilers in the St. Denis station. But their experience is too short to warrant definite conclusions. It is significant that the new Ivry station, placed in service about the end of 1927, is at present entirely stoker-fired.

In the coal mining districts, pulverized coal is gaining ground, in spite of the relatively small size of the individual stations, and, at present, the limited market open to them.

Coal Pulverization

Efficient pulverization is one of the most difficult problems in the use of pulverized coal in France. After prolonged tests of other types of mills, "Union d'Electricite" considers that the type best suited to handling French coals is the conical ball mill, in spite of its higher first cost and power consumption. This type has been chosen for the new Vitry station. This opinion is apparently shared by "Cie. Parisienne de Distribution d'Electricite," mills of this type having been chosen for the extension of the Issy-les-Moulineaux station. "Soc. d'Electricite de Paris" have used Fuller screen mills in their pulverized coal plants, and a number of other French stations use roller or impact mills.

Firing Methods

The policy of "Union d'Electricite" tends toward direct firing; but it is admitted that present attempts have not proved entirely satisfactory, for lack of a type of mill whose air requirements under variable loads can be made to coincide even remotely with the primary air requirements of the furnace. The solution at present favored by this company, and adopted for the new Vitry station, is semi-direct firing, with storage capacity only sufficient to take up the load fluctuations. It is considered, however, that present types of individual mills would prove satisfactory for relatively constant load conditions. "Cie. Parisienne de Distribution d'Electricite" has adopted a central pulverizing plant for the Issy-les-Moulineaux extension, with a compressed air transport system.

Pulverized Coal Furnace Construction

Completely water-cooled furnace walls are not in great favor as yet with the three Parisian power groups. It is considered that, with low volatile fuels such as they are frequently obliged to use, combined with long-flame firing, the load range for satisfactory combustion in such furnaces is too narrow to meet the exacting service conditions. "Union d'Electricite" favors a construction composed of ordinary tubes without fins, widely spaced, and set forward with respect to the refractory wall. Nevertheless, an interesting experiment is under way in the Gennevilliers station. One of the original 14,000 sq. ft. Babcock boilers has been remodeled by removing the stoker and building within the original furnace two octagonal-base combustion chambers, composed of Murray tubes. A turbulent burner of the "International Combustion" type was placed at the bottom of each chamber. This experiment is still under way, and seems to be giving satisfaction. Ash-pit water screens are used in all the furnaces of this company.

"Cie. Parisienne" has adopted for three boiler furnaces built by "Soc. Anon. des Foyers Automatiques" in the Issy-les-Moulineaux extension, the standard "Lopulco" long-flame firing system, with Murray tubes on the rear and side walls, and an ash-pit water screen. The two remaining furnaces, built by "Soc. Anon. pour l'Utilisation des Combustibles," comprise water tubes without fins on all four sides of the furnace, spaced close together, and faced with fire brick over all but a section of the side walls.

The three "Lopulco" furnaces in this plant embody a novel solution of the troublesome problem of water-screen connections under high pressures. As shown in Fig. 1 and 2, instead of using large tubes with flanged joints for the downcomers, standard boiler tubes have been adopted in sufficient number to give the required cross-section, these tubes being rolled into the lower water-screen header and into the boiler drum, so that the boiler does not include a single flanged joint. The solution is said to be both cheaper and safer than that using larger tubes.

In the St. Denis station, "Soc. d'Electricite de Paris" has adopted water-cooled walls faced throughout with refractories.

Outside of the Paris district, water-cooled walls and turbulent firing are gaining ground more rapidly. Fig. 3 and 4 show in elevation and plan an unusually compact project designed by "Soc. Anon. des Foyers Automatiques" for an industrial plant of a capacity per unit of 100,000 lb. per hr. It includes a Wood steam generator, with corner firing, an air preheater in two sections separated by the inlet air duct, the forced and induced draft fans being respectively located beneath and above the air preheater. In this case indirect firing is to be used.

Fig. 5 shows another type of furnace, designed by "Soc. Anon, des Fours STEIN," and adopted for a number of medium size boiler furnaces. Direct firing is used, with drying in the mill with hot air drawn across the bottom of the furnace, thus forming an "air screen" for the purpose of cooling the ashes. The furnaces being under forced draft, the cold air is not used for combustion until after it has passed through the mill. The furnace walls are not cooled.

Steam Pressures and Temperatures

Progress in steam pressures has been guarded in France. The new Vitry station of "Union d'Electricite" is designed for 550 lb.; a higher pressure was not adopted so as to avoid the expense of solid forged steel drums. In these boilers the drums are forge-welded, the heads being riveted. If the load factor of this station had been more favorable, a considerably higher operating pressure would have been justified.

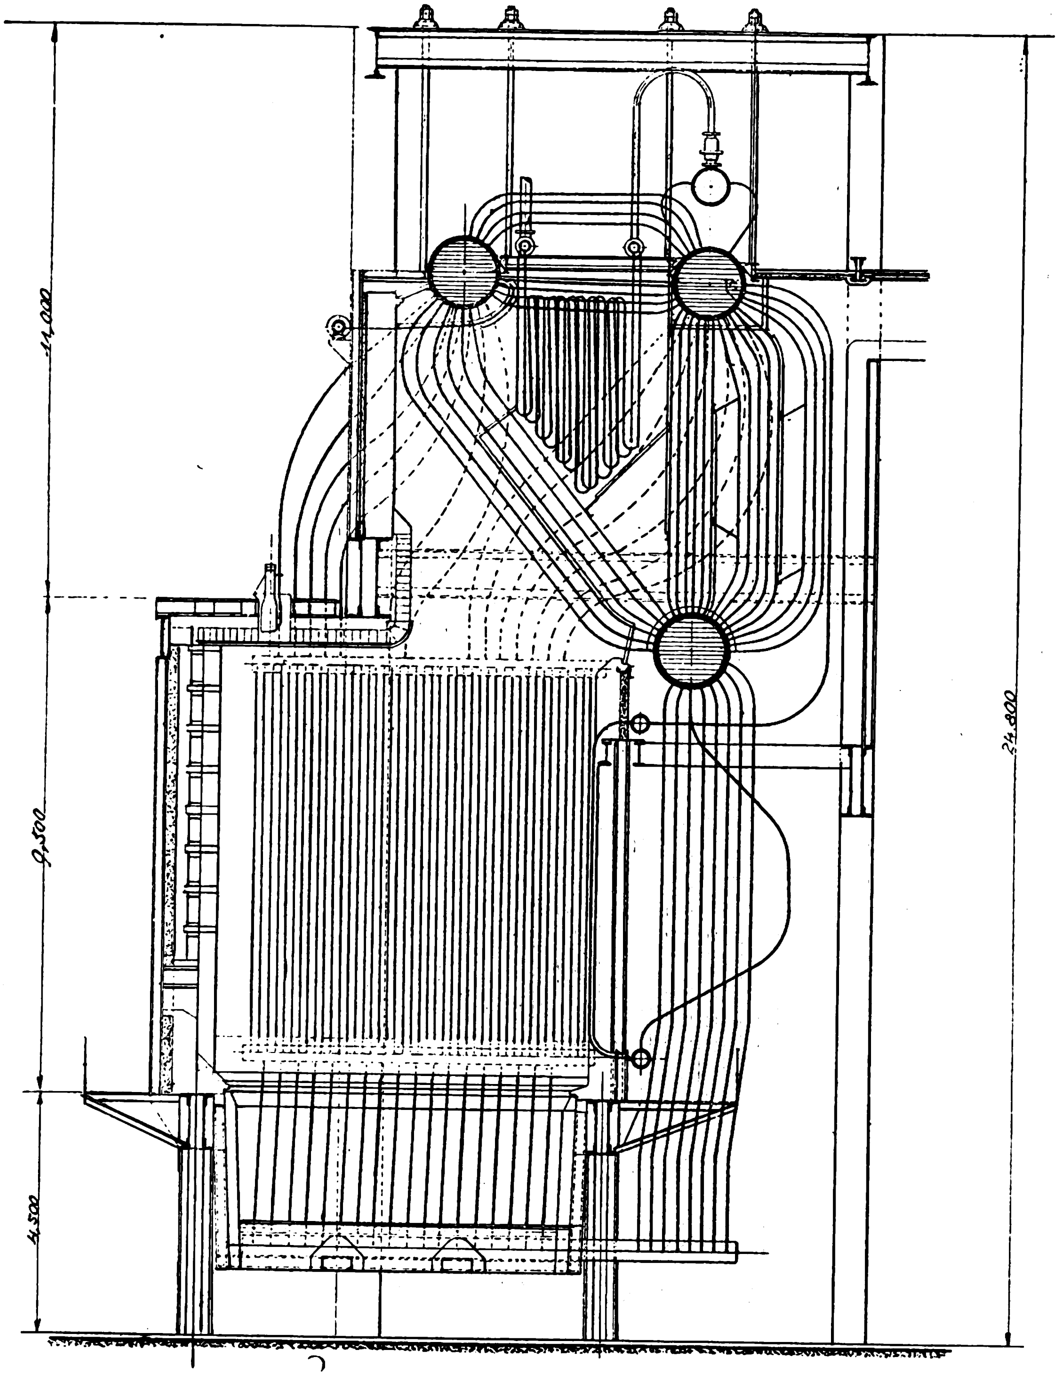

FIG. 1—"LOPULCO" FIRED BOILER FOR 625-LB. STEAM PRESSURE, IN EXTENSION OF ISSY-LES-MOULINEAUX STATION, PARIS.

The extension of the Issy-les-Moulineaux station of "Cie. Parisienne" is designed for 625 lb. at the boiler, and has solid forged-steel drums. In this case a higher pressure was not adopted so as to avoid the necessity of reheating the steam during expansion.

"Soc. d'Electricite de Paris" has as yet made no substantial advance in pressures, the Ivry station being built for 310 lb. at the boiler. But several types of steam generators adapted to higher pressures are under careful study by this company, such as the Rauber, Benson, Loeffler and Schmidt systems.

Steam temperatures are generally somewhat higher than those used in current American practice, owing in a measure to the general aversion in France to reheating. A temperature of 800 deg. fahr. at the turbine throttle is considered safe in most power circles.

Present tendencies in pressures and temperatures seem to justify the conclusion that the principal obstacle to the use of higher steam pressures in France is the high cost of the boilers and turbines. It is likely that a radical change in boiler design to reduce the cost, together with a reduction in the cost of certain existing uncorrodable alloys through improved production methods, would open the way for a considerable increase in pressure and a substantial rise in temperatures.

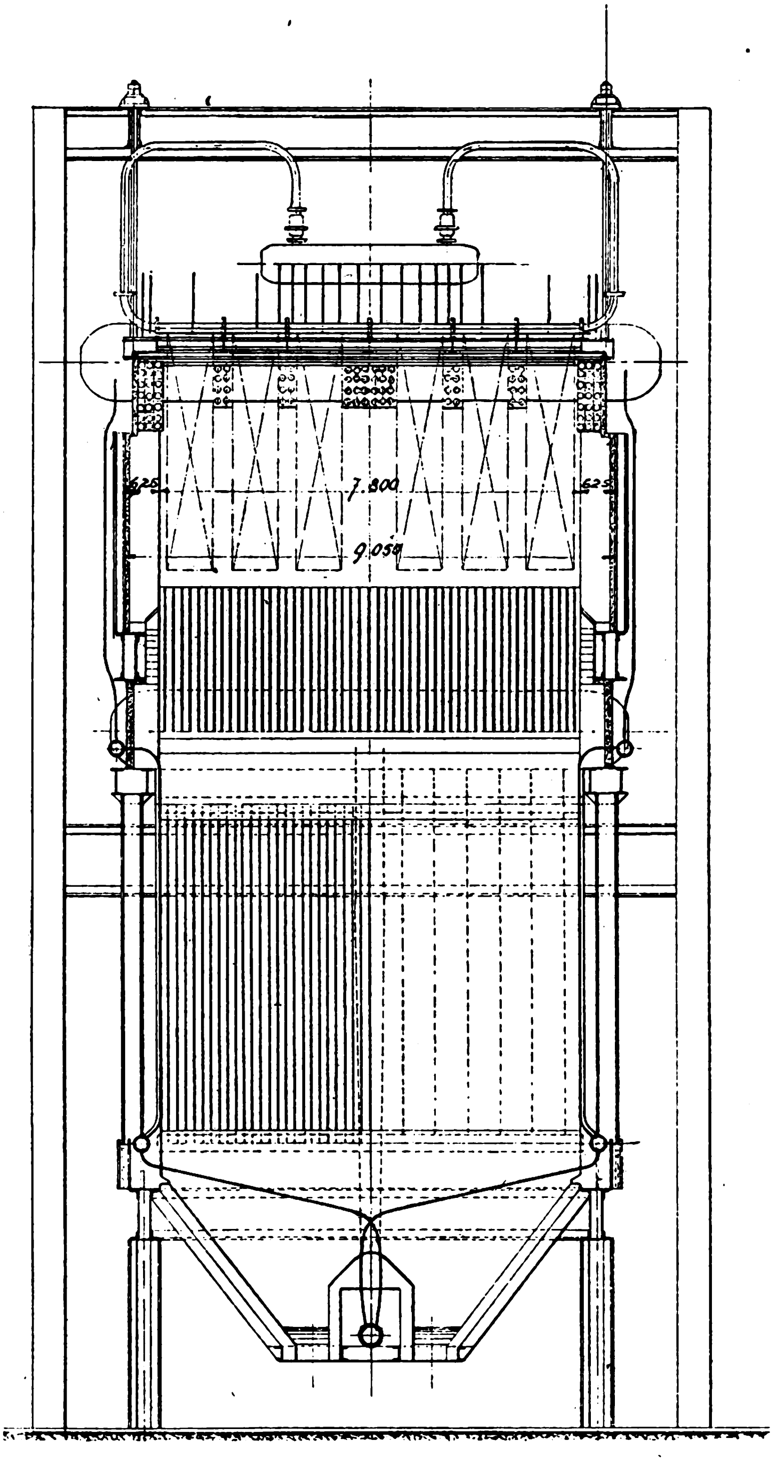

FIG. 2—ELEVATION OF FIG. 1.

Novel Boiler Designs

In general, there has not been much practical advance in boiler design. An interesting innovation is the Rauber-Babcock boiler, which extends to the boiler the use of transverse fins common in economizer construction, to reduce the resistance to heat flow at the contact surface between gases and boiler tubes, and make the convection heating surface more effective. Fig. 6 shows a cross-section of a Rauber experimental unit. Fins of different diameters are welded onto the tube surfaces, so as to make the total contact surface in successive rows of tubes approximately inversely proportional to the temperature difference between the gases and the water. Based on the area of the tube surface without the fins, average evaporation rates of over 30 lb. of steam per sq. ft., or 1000 per cent rating, have been obtained in a small experimental boiler, and over 40 lb. per sq. ft. are expected from larger units.

Two 3100 sq. ft. Rauber units are under construction for the Troyes central station. A number of other units, ranging up to 300,000 lb. capacity, 1000 lb. pressure and 930 deg. fahr. temperature, are at present under study; also a small

experimental boiler for the very severe steam conditions of 2800 lb. pressure and 1100 deg. fahr.

Steam Turbines

The trend of turbine design in France is clearly toward improvement in workmanship and in materials, for the purpose of raising the mechanical efficiency. "Union d'Electricite" favors the three cylinder tandem design, with nozzle blocks and blading of uncorrodable materials. The machine work is exceptionally good, with the result that the last two 55,000 kw. units of the Gennevilliers station, respectively built by "Brown-Boveri" and by "Soc. Alsacienne de Constructions Mecaniques," are said to have given on test mechanical efficiencies as high as 87 and 88 per cent.

An interesting experiment is being tried in the Gennevilliers station to make use of obsolete turbines. The first ten stage impulse turbine installed in this station is being equipped with a high-pressure cylinder in tandem with the original cylinder. The throttle pressure remains unchanged, but expansion will take place in twenty-four instead of ten stages. In this way, the capacity of the unit is to be increased from 35,000 to 45,000 kw. with a material improvement in efficiency.

"Cie. Parisienne" is installing in the Issy-les-Moulineaux extension two 11,000 kw. back-pressure units exhausting either directly into two existing 40,000 kw. units, or into the existing 200 lb. mains; also one 35,000 kw. condensing unit.

Condensation

Considerable experimental work is under way in connection with condensation. Probably the outstanding innovation is the four condenser arrangement of the two last units in the Gennevilliers station. These turbines exhaust at four points on 45 deg. diameters, into four horizontal condensers arranged in two tiers, two substantially at the

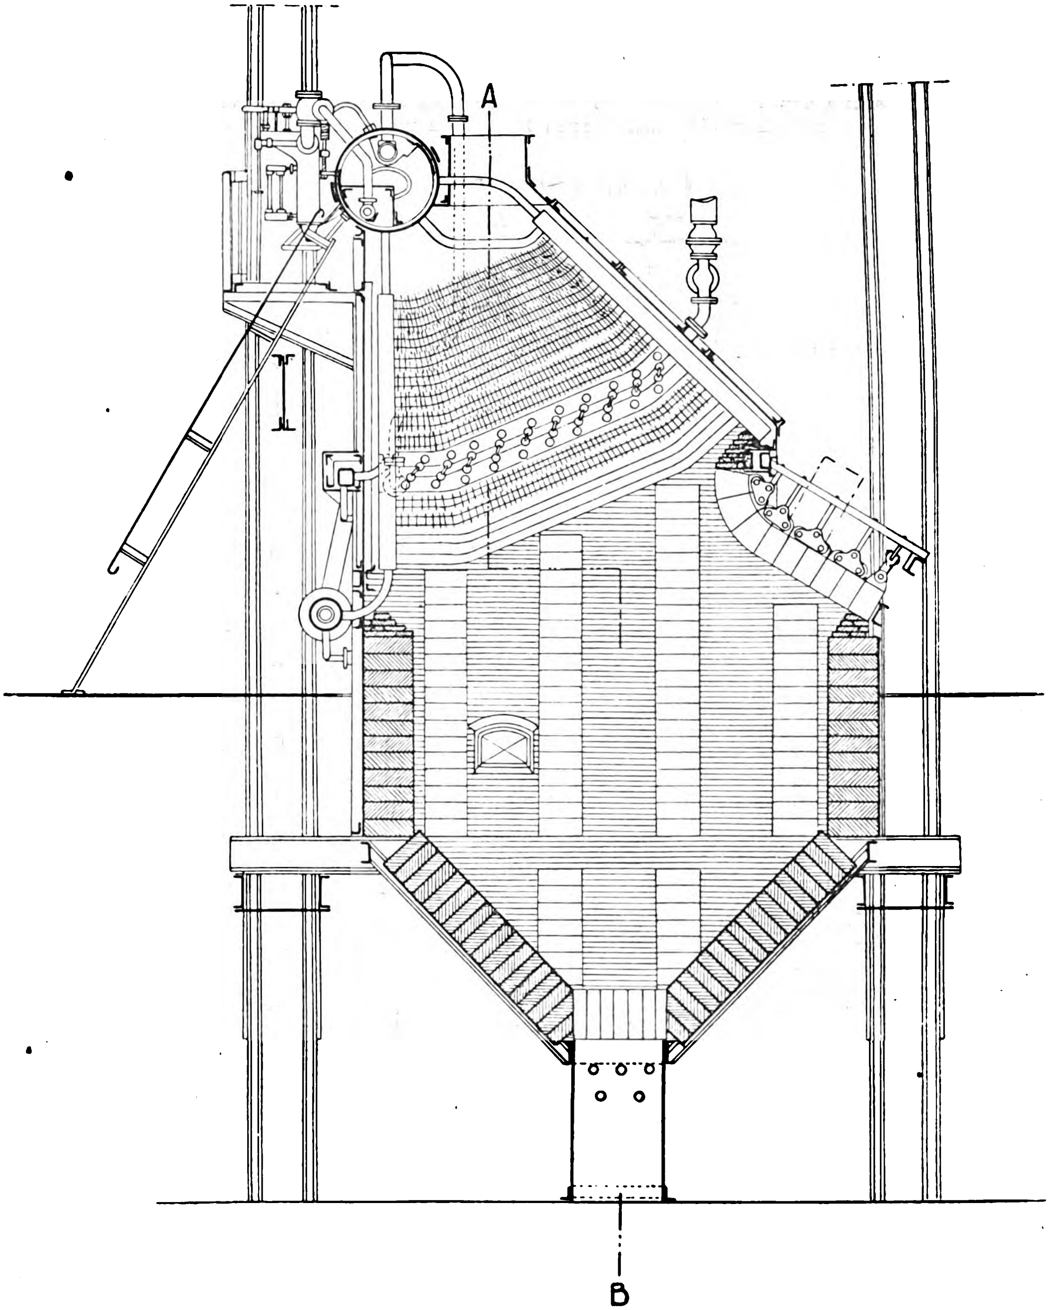

FIG. 6—EXPERIMENTAL RAUBER-BABCOCK FIN TUBE BOILER.

level of the turbine, and two in the basement. This arrangement is said to have given good vacua and a substantial reduction in the losses in the exhaust casing. However, some difficulties were encountered through the wide fluctuations in condensing water level, owing to syphon operation of the upper condensers. It seems that this arrangement should be limited to fairly constant condensing water supplies. It has not been adopted for the new Vitry station, where the variations in the Seine level are still greater than at Gennevilliers.

Dust Precipitation

Study of dust precipitation has not generally been as active as in the United States, but several systems are on trial. At the old Vitry plant of "Union d'Electricite," electrostatic precipitation has been tested, also a flue gas washing system. In the latter, the gas passes through a chamber filled with cast iron columns over the surface of which flows a film of water. The columns are so shaped as to leave between them a number of winding passages, for the purpose of bringing the dust particles in contact with the water. The results are said to be encouraging.

An interesting installation has been made in the Comines central station, in the northern coal region. This is known as the "Ostricourt-Pauthenier" system, and is a simple improvement of the electrostatic system of precipitation, which materially reduces its bulk and cost. It consists in creating in front of the precipitating plates a neutral zone of about 1¼ in. in depth, protected from the moving gases by suitable baffles, and from the induction effects by a wire netting grounded with the plates. The result is to greatly increase the rate of precipitation, and to allow a considerable increase in gas velocities.

The apparatus at Comines is installed on an 11,000 sq. ft. boiler, between the boiler proper and the economizer. Its volume is about 770 cu. ft. In six months of service, the dust separation is said to have averaged between 90 and 95 per cent. Its maximum power consumption is 2.5 kw. The voltage used is 30,000 to 50,000.

Another system of dust separation in two steps has been applied in several plants in France and Belgium, and is said to give satisfaction. It was developed by "S. A. des Fours Stein," and is based on a preliminary separation by centrifugal force, followed by washing of the gases.

The Electric Current Supply of Berlin, Germany

STATEMENT BY DIPL. ING. M. REHMER, BERLIN

(From "Elektrizitaetswirtschaft," Vol. 27, p. 278)

Berlin is supplied with electric current by seven companies of which the more important is Berliner Staedtische Elektrizitaetswerke A. G., known as "Bewag."

The large number of companies is explained by the recent history of Berlin, the formerly independent suburbs having long time agreements with the individual companies.

The Bewag supplies 88 to 90 per cent of the total energy consumed to about 80 to 85 per cent of the total area of the city and can be considered as representative for the entire energy supply.

The Bewag has had a development during the last four years which is without precedence in the German electrical industry. The system peak load has increased from 142,000 kw. in 1923 to 356,000 kw. in 1927 (see Fig. 7). The average yearly increase, therefore, was 53,000 kw. The base load increase was about half of this amount per year.

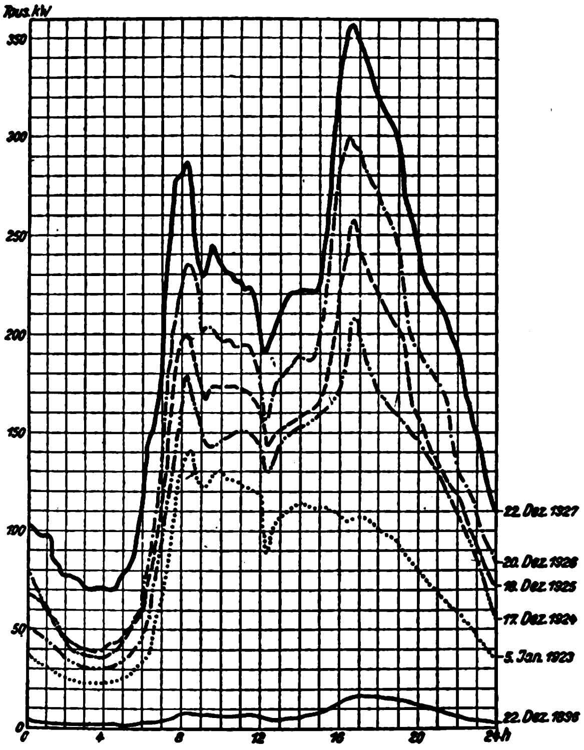

FIG. 7—LOAD CURVES ON PEAK LOAD DAYS OF THE YEARS 1896, 1923 TO 1927.

Table II shows the increase in the consumption of electric energy. The total energy generated and purchased increased from 480.7 million kw-hr. to 1,025.4 million kw-hr. within four years. There is no indication of a slowing down of this development in the near future. The consumption of electric energy per inhabitant has been doubled within four years. Since the necessary increase of the means of production cannot be secured by acquiring other companies, the future development demands a large extension of the generating capacity.

TABLE II

TOTAL ENERGY GENERATED AND PURCHASED BY BEWAG

Year	Kw-hr. Generated, Millions	Kw-hr. Purchased, Millions	Generated, Per Cent	Purchased, Per Cent
1923	151.5	329.2	31.52	68.48
1924	193.5	358.0	35.08	64.92
1925	365.2	383.9	48.75	51.25
1926	412.1	396.7	50.95	49.05
1927	686.5	338.9	66.95	33.05

Year	Total Kw-hr. Generated and Purchased, Millions	Connected at the End of the Year, Kw.	Billed Kw-hr., Millions	Number of Customers Within City	Kw-hr. per Inhabitant per Year
1923	480.7	489,749	426.7	127,873	122.8
1924	551.5	531,756	451.0	278,217	129.6
1925	749.1	741,417	651.9	362,996	183.2
1926	808.8	801,233	705.1	435,280	194.7
1927	1,025.4*	....	898.9	542,834	239.5

*This figure does not include the energy purchased from B.V.Œ.W., M.E.W. and St.u.Kr.Krftw. Spandau for Spandau, which was 53.7 million kw-hr.

In planning for this rapid expansion both generator and transformer capacity are chosen to correspond to the peak load conditions. A spare capacity of 25 per cent for the generation and of one transformer each in the transformer stations are included. The conclusion is that a total peak load of 740,000 kw. with a base load of 400,000 kw. will be the demand in 1932. About 425,000 kw. generating capacity and 408,000 kw. transformer capacity must be added to the present equipment to carry this load.

Fig. 8 shows the load curves of the Berlin system. A study has been made of the peak load problem. The solution, however, has been postponed until later, since the peak load becomes base load within about three years at the present rate of development. The problem will be more urgent when the development slows down. A solution of the peak problem by adjusting the rates has been tried out without success, as far as the load conditions are concerned. However, the influence of the short time demands can be effectively counteracted by determining accurately the range of use of the varying means of production, as shown in Fig. 9. A Ruths steam accumulator plant of 40,000 kw. capacity will be ready for service in 1929. The purchased high tension capacity will be 50,000 kw. The battery capacity available is 40,000 kw. The possibility of using Diesel engines in local peak load stations is limited in Berlin. The present economical situation does not justify the erection of a water power plant in the proximity of Berlin.

The principal problem of the next few years, therefore, is the increase of the power plant capacity and, correspondingly, of the available outside capacity. Operation at a new plant in Western Berlin is planned for 1930 and further units will be added to the older plants. Ruths steam accumulators are not only cheap peak load capacity, but also provide spare capacity available for immediate use. Furthermore, they have the advantage of decreasing the amount of smoke. The smoke problem in the cities will be brought closer to a solution by connecting the heating to the generation of power. It seems possible that a combination of heat and power generation will be of advantage, also, economically.

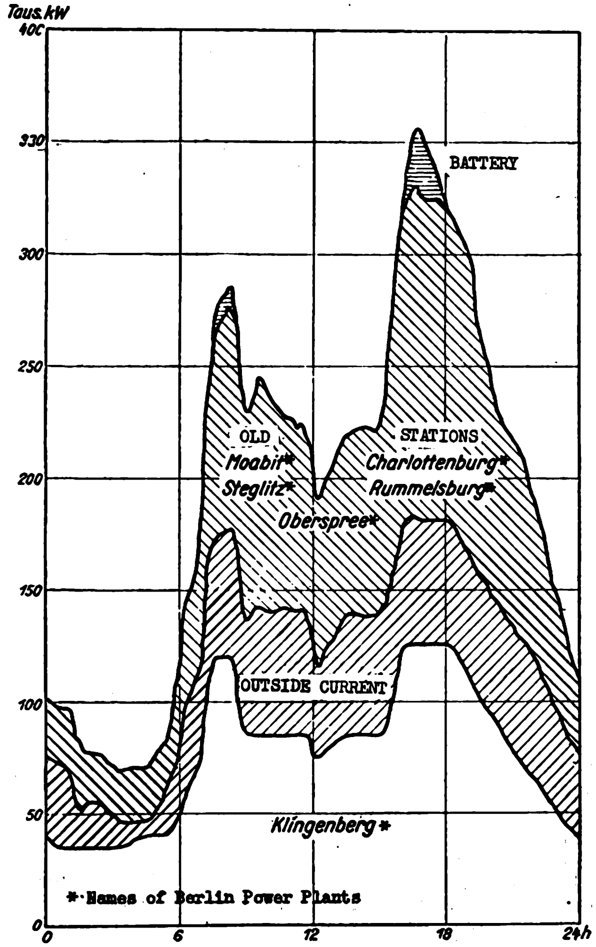

FIG. 8—TOTAL LOAD OF THE BEWAG, DEC. 22, 1927.

The load distribution for the different sources of power for 1932 is shown in Fig. 9. The different means of supplying energy are used according to their individual characteristics.

It seems probable that the demand will force the use of a larger amount of outside current after 1932. Coal mines have been acquired at the Elbe and Oder rivers and power plants will be built at these mines later on. The outside current, then, will be furnished by our own coal burning plants and by the present lignite burning stations. The main stations in the east and west of the city will be interconnected by a 100,000-volt ring cable, a 100,000- to 30,000-volt substation to be erected in each half of the ring to receive the outside current.

Recent High-Pressure Boiler and Turbine Plants in Holland

(*From "Science Abstracts"* 3—*January,* 1928)

CONFERENCE DES GRANDS RESEAUX ELECTRIQUES, PARIS (28 PP.) 1927

The report contains descriptions of the construction and tests of new boiler and turbine plants at three Dutch power stations. All the boilers are of the Babcock & Wilcox cross-drum, vertical-header type, manufactured by Stork Bros. and the turbines are also by the same firm.

At Utrecht the new boilers have a heating surface of 6430 sq. ft. each and generate at normal load 44,000 lb. per hr. at 510 lb. and 800 deg. fahr. They are fired by mechanical stokers. The efficiency at normal load was 87 per cent based on the lower calorific value. The 16,000 kw. turbine comprises one high-pressure, one intermediate and two low-pressure cylinders. The steam consumption at full load was 8.44 lb. per kw-hr.

Among the other boilers described is one of 15,500 sq. ft. working at 620 lb. and equipped with a combustion chamber on the Lulof system for powdered fuel.

The New Central Station at Buenos Aires

STATEMENT BY VON JANLET, BRUSSELS

The initial installation consists of two turbines having a total capacity of 105,000 kw., the ultimate capacity to be 600,000 kw-hr.

Before starting the station, the company engineers obtained considerable data in 1925 on a trip to the United States on such stations as Philo, Twin Branch, Crawford Avenue, and Columbia. In building the new station at Buenos Aires, it is apparent that the engineers followed the design characteristics of the above stations very closely. A steam pressure of 550 lb. was selected for the turbines, using reheat for the low pressure cylinders.

Coal Pulverization

A 45-ton per hr. Lopulco pulverizing system is installed, one mill being held in reserve. Revolving plate dryers heated by steam are used.

Boiler Installation

Six standard and two reheat boilers are provided for 650 lb., 797 deg. fahr.

The standard boilers have 15,392 sq. ft. heating surface with 5414 sq. ft. superheaters, 11,065 sq. ft. economizers and 27,007 sq. ft. air preheaters. As the boilers are provided with water walls and water screens, a maximum of 14 lb. per sq. ft. per hr. evaporation may be attained.

The reheat boilers contain 3890 sq. ft. of heating surface with 2874 sq. ft. superheaters, 6997 sq. ft. economizers and 27,007 sq. ft. air preheaters. The reheater heating surface is 19,160 sq. ft., which will reheat 400,000 lb. of steam per hr. at 131 lb. gage and 432 to 752 deg. fahr.

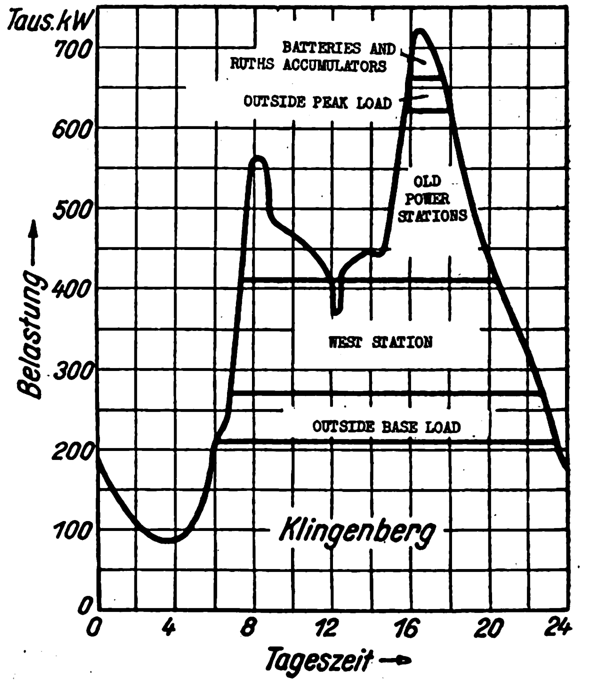

FIG. 9—ANTICIPATED LOAD CURVE OF BEWAG SYSTEM, DECEMBER, 1932.

Turbo-Generators

Two turbo generators use reheating for the low pressure cylinders and heat the condensate with extraction steam.
Turbine capacity—52,500 kw. at 1500 r.p.m.
Throttle steam pressure—550 lb. per sq. in. gage.
Steam temperature—752 deg. fahr.
High pressure cylinders have nine stages. Low pressure cylinder, 17 stages.
Reheat-Superheat—770 deg. fahr.
Steam is extracted from 12th, 16th, 20th and 23rd stages.
Worthington condenser—52,500 sq. ft.
House turbine directly connected to main generator·2500 kw.

Condensing Water

Condensing water is taken from the La Plata River and passes through screens automatically cleaned by sprays. Circulating pumps are of a vertical type and are arranged to overcome friction losses only.

Piping

American high pressure standards were adopted, using Sargol flanges. The majority of the valves are either Crane or Edwards and are motor driven.

Fuel Control in Industry

STATEMENT BY DR. F. MUNZINGER

(*Abstracted from "Engineering," Nov.* 30, 1928)

The coal consumption of many stations was higher than necessary in view of present-day technique, owing to their poor average load factor; and this was also the reason why extra high pressure feed water heating by extracted steam, pulverized fuel, etc., had not been more widely used. The principal means of obtaining cheaper electricity were: High pressures, the employment of more perfect working processes, and machines and measures for lessening the price-raising effect of peak loads on operating and capital costs. These factors were partly contradictory in their effect, and must be balanced in order to improve the overall economy.

As regards the cost of a modern generating station, it was pointed out that this was largely dependent on size, steam pressure and operating conditions, including the existence of interconnection with other stations. The total cost of the Klingenberg station, which was the most modern in Germany, was £3,148,000, and its capacity being 270,000 kw., its specific initial cost was £11 13s. per kw. About 5500 kw. of this capacity was required for "house" purposes, the cost per salable output was £12 per kw. The operating cost was only about 50 per cent of pre-war figures, and the heat consumption at full load did not exceed 14,200 B.t.u. per kw-hr. as compared with the 20,500 B.t.u. of the older stations. As regards the effect of higher steam pressures on the cost of a station of this size, taking a figure of 100 for a pressure of 500 lb., the corresponding values for 850 lb., and for 1400 lb., would be 104.3 and 109.9 respectively.

The most economical steam pressure was that at which the cost of production was lowest. For instance, with a load factor of 37 per cent, 12 per cent interest on capital, and coal at 12s. per ton, a pressure of 500 lb. would be most economical, but with coal at 24s. per ton, an 800 lb. pressure would show an advantage, though the difference was slight. In general, the economic region of 500 lb. was greater the higher the capital charges and the lower the price of coal. A pressure of 1400 lb. was only feasible when the capital charges were low, and the price of coal and the load factor high. At load factors below 30 per cent, pressures much exceeding 500 lb. were only noticeably advantageous under extreme conditions.

The high capital cost necessary to supply the peak load output might be reduced either by heavily loading the boilers or by the use of Ruth's accumulators, the latter precedure being more advantageous at high than at low pressures. The overall cost of such accumulator plant was £8 to £9 per kw., compared with £12 to £14 per kw. for boilers. Five traction stations and four ordinary stations in Germany were equipped with this type of plant. Of the latter, the largest equipment was that at Charlottenburg with a capacity of 177,000 cu. ft. and a pressure range of 185 to 7.2 lb. per sq. in., allowing 70,000 kw-hr. to be accumulated and a peak up to 40,000 kw. to be met. Accumulators and special boilers supplemented each other admirably, and even when the latter had a very small water content, dangerous surging was entirely prevented.

Boilers, Superheaters and Economizers

STATEMENT BY BABCOCK & WILCOX, LTD., LONDON, ENGLAND

During the past year we have perfected and put on the market a Babcock Low Temperature Coal Distillation System, which is of interest in the boiler world in that it is specifically designed to work in conjunction with steam raising plant.

By this process coal is first preheated and then put through a distillation retort in which the valuable tar vapors are distilled off, and from which semi-coke is withdrawn and fed straight on to the mechanical stokers under the boiler, or passed to the pulverizing mill and subsequently burned in a pulverized fuel furnace.

A full description of this process, together with numerous illustrations of the plant, which has been in successful operation for two years at the Dunston Power Station of the Newcastle Electric Supply Co., is issued in pamphlet form and can be had on application to Messrs. Babcock & Wilcox, Ltd., Babcock House, London.

Its essentials consist of a preheater, heated by means of flue gases from the boiler, in which the coal is dried. From here the coal passes to a mechanical feeder, which distributes it evenly in the retort, which is internally heated by means of a mixture of steam and hot gas from an independently fired combustion chamber. The tar vapors are taken out from the top of the retort, and after passing through a filter for the purpose of removing any coal dust, are condensed and passed through an ordinary refining plant.

A high thermal efficiency is obtained with this plant. In addition to 76 per cent of the original thermal value of the coal which is available under the boiler and the advantage of a smokeless fuel, there is obtained a valuable range of low temperature byproducts which make possible the more economical generation of electricity.

Our experience during the past year, which covers all countries, except the North American continent, seems to indicate that pressures which show a tendency to rise to 1200 lb. per sq. in. and over will not, in general, exceed 500 to 600 lb. per sq. in., with final steam temperatures up to 800 and 900 deg. fahr. To meet these conditions we have installed at our Renfrew Works a new plant, which includes what we believe to be the largest hydraulic press in the world. This will enable us to supply riveted drums for pressures up to the above limit, instead of the more expensive solid forged type. This press is capable of exerting a pressure up to 8000 tons, and will deal with plates up to 40 ft. 0 in. long, 2¼ in. thick, bending them to three-quarters of a circle up to 4 ft. 6 in. diameter. A full description of this press and the planing machines used in conjunction with it was given in the British periodical, *The Engineer*, dated Dec. 7, 1928.

In view of the increasing importance of dry, clean steam, we have developed and patented a new vane type dry pipe.

The steam, in passing through the nests of inclined vanes, is freed of its impurities and moisture, which collect in the covered troughs beneath, and are disposed of through either internal or external drains. The vanes are of mild steel, which has been found quite satisfactory in service, and the dry pipe is made up of standard sections so that it can be made in various sizes at a minimum cost.

This vane type dry pipe has proved highly successful in practice, both from the point of view of increased efficiency in the superheater and as a protection against clogging and erosion of turbine blades. In one case the replacing of a standard dry pipe by one of this vane type produced an increase of 50 deg. fahr. in the superheat, and reduced the moisture content from 4 per cent to less than 1 per cent.

Stokers

During the past year we have also developed an improved design of chain grate stoker to meet the demand for larger units. This is known as our style 28 stoker and can be made up to 30 ft. 0 in. wide by 24 ft. 0 in. long. It is of the drop-link type and is so constructed that all the load is taken on massive driving chains spaced across the width of the stoker, the links being free from any thrust or tension. Improved air distribution is obtained by damper control to the compartments, and an effective clearing action is obtained by arranging for alternate links to drop when the chain goes over the back end.

Brown-Boveri High-Pressure Boilers

Statement by Dr. Paul Faber, Brown-Boveri Co., Baden, Switzerland

High-pressure boilers from 800 to 1500-lb. pressure have been built successfully on the same principles as low-pressure boilers, using both the sectional system and the vertical tube system. These boiler designs applied to high pressures result in thick walls and, therefore, in heavy weights and high prices. Other disadvantages of the old boiler systems, such as danger of incrustation, insufficient adaptability to changing loads, priming because of uneven production of steam in the tubes, expansion through heat, etc., are still more noticeable with high pressures. It is clear, therefore, that the future high-pressure boiler will not consist in an "adaptation" of the low-pressure boiler. A series of special designs of high-pressure boilers have arisen. We mention the boilers of Benson, Brown-Boveri, Loeffler, Schmidt. It is typical of all these that they avoid evaporating the water on walls in contact with the fire. Benson heats water without actual evaporation at or above the critical pressure and temperature, and produces steam by expanding down to a lower pressure. In the Loeffler boiler steam is superheated by the heat of the fire and carried to the water where it loses its superheat in evaporating part of the water. Three to four times the steam output is circulated as a heat carrier. Schmidt uses a closed water circuit under high pressure as a heat carrier.

Brown-Boveri also employs superheated steam to transfer heat, but avoids the circulating blower and its energy losses which, from an operating and designing point of view, are unsatisfactory. The steam circulation is maintained by natural pressure drop through the various stages of evaporation. The original and simple principle of the Brown-Boveri steam generator is illustrated in Fig. 10. In a very small "exciter boiler" "1" a small percentage of the desired steam output is raised to a pressure somewhat above the delivery pressure of the boiler. This steam is heated in a first superheater "2." It then flows through a first evaporator "3" to which preheated feed water is supplied from the tank "15" by the pump "14" and injected through nozzles. The superheat of the steam serves to evaporate a certain part of the water.

The flow of steam, increased by the newly evaporated water, goes to a second superheater "4," absorbs a further quantity of heat and carries it to a second evaporator "5" turning a further quantity of feed water into steam. The volume of steam is again increased, goes to a third superheater "6" and so on, until after a number of stages the desired output of steam is reached, which then flows through a last superheater "12" to the engines. In flowing through the stages of the boiler, the pressure of the

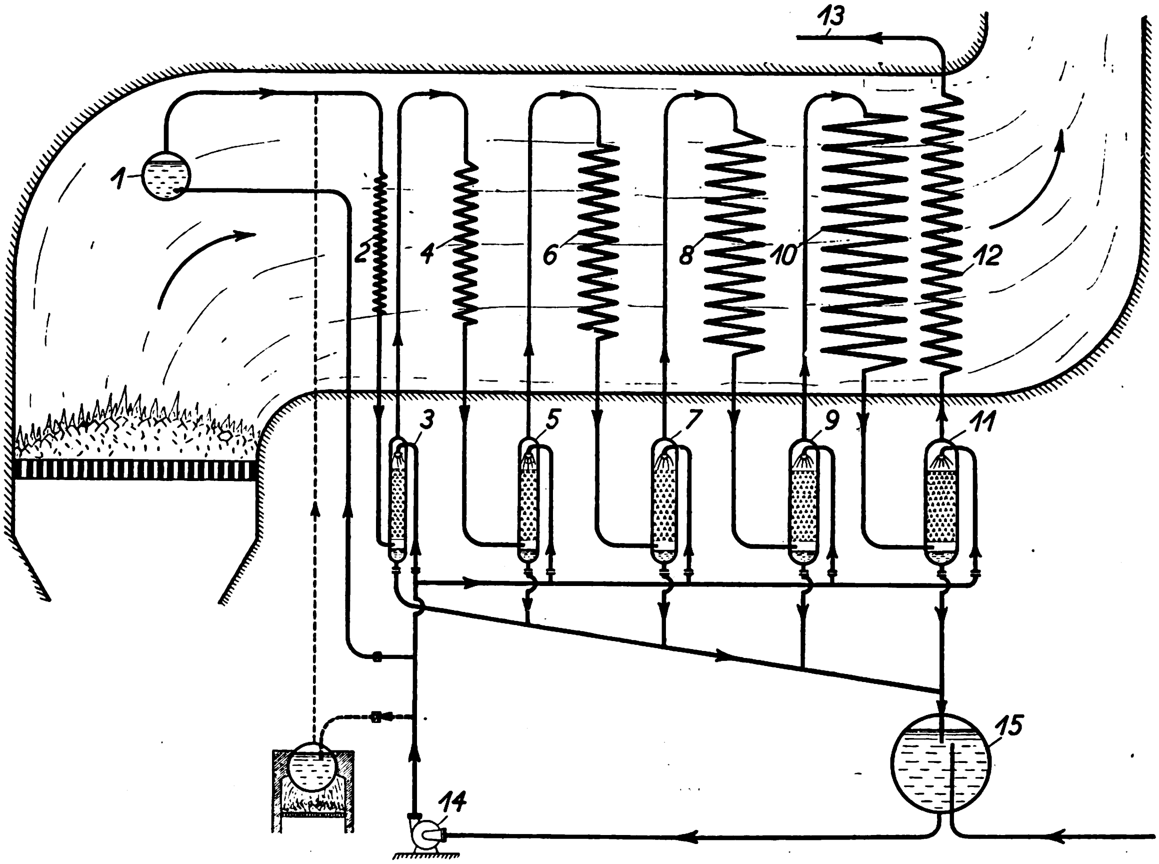

FIG. 10—Principle of the Brown-Boveri Steam Generator.

steam will drop somewhat, according to the resistance encountered through the superheaters and evaporators. However, no energy loss arises from it and, furthermore, the circulating blower is avoided.

Assuming the weight of the exciter steam to be w_1 and its total heat i_1, assuming further this steam to be superheated to a total heat i_2 and feed water of the temperature t_0 and of the total heat i_0 injected, the amount of steam evaporated in the first stage will then be:

$$\Delta w_1 = w_1 \frac{i_2 - i_1}{i_1 - i_0}$$

After n-stages, we obtain a steam output of:

$$w_n = w_1 \left[1 + \frac{i_2 - i_1}{i_1 - i_0}\right]^n$$

neglecting in the formula the small drops in pressure and temperature from stage to stage. With a pressure of 1500 lb. and a temperature raised in the superheaters to 900 deg. fahr., and with 500 deg. fahr. feed water, the amount of steam is increased by about 40 per cent in each stage. Therefore, starting with 5 per cent exciter steam, the full output is reached in 9 stages.

The principle of the Brown-Boveri stage boiler may be put into practice as shown in Fig. 11. The exciter boiler is omitted from the figure. Being small, it may be built according to any known system and heated either by the main fire or from a separate furnace. The superheater may be built of thin wall tubes of about 1-in. diameter, without regard to circulation of water or extraction of steam. The weights may be kept small. In consequence of the high steam pressure, the heat transfer coefficient from the superheater tubes to the steam is very high, reaching as much as 200 to 250 B.t.u. per sq. ft. per deg. fahr. per hr. The temperature of the tubes is, therefore, little above the steam temperature.

The evaporators consist of simple drums placed outside the furnace and are easily accessible. Means are provided for suitably guiding the injected water and the steam. An excess of feed water may be supplied or the necessary rate maintained by a float valve. The tank "15" is made larger or smaller, depending upon the desired heat accumulating capacity of the boiler. Preheated feed water may be supplied from this tank or cold feed water from a reservoir. This tank acts to a high degree as an equalizer on rapid fluctuations of load. In the combustion chamber a large portion of the heat is transmitted by direct radiation to the heating surface. The high temperatures of the tubes and of the preheated combustion air prevent the fire from being excessively chilled. Large brick settings are done away with, which results in low prices and low starting and standby losses. Due to the small masses of brick work, the Brown-Boveri steam generator is well suited to take up rapid load changes and peak loads. The water is not heated through contact with a wall. Therefore, incrustation of the heated walls from impure water is impossible. The deposits drop to the bottom of the evaporators, where they are harmless and may be removed by replacing the soiled filter pieces by clean ones.

The advantages of the Brown-Boveri stage-boiler may be summarized as follows:

1. No heat transfer from a wall to the water. Insensibility to impure feed water. No incrustation of the heating surfaces; no priming.
2. Thin tubes for heating surfaces; light weight of the boiler; rapid adaptation to load changes; low prices.
3. Light water drums away from the fire; no weakening of the walls with water tubes.
4. The water level in the drums may be varied to give a large heat storage capacity suitable for peak loads.
5. Owing to small masses of brick work, small heating and standby losses; low first costs and maintenance; boilers suitable for rapidly fluctuating and peak loads.
6. No high-pressure circulating blower required.

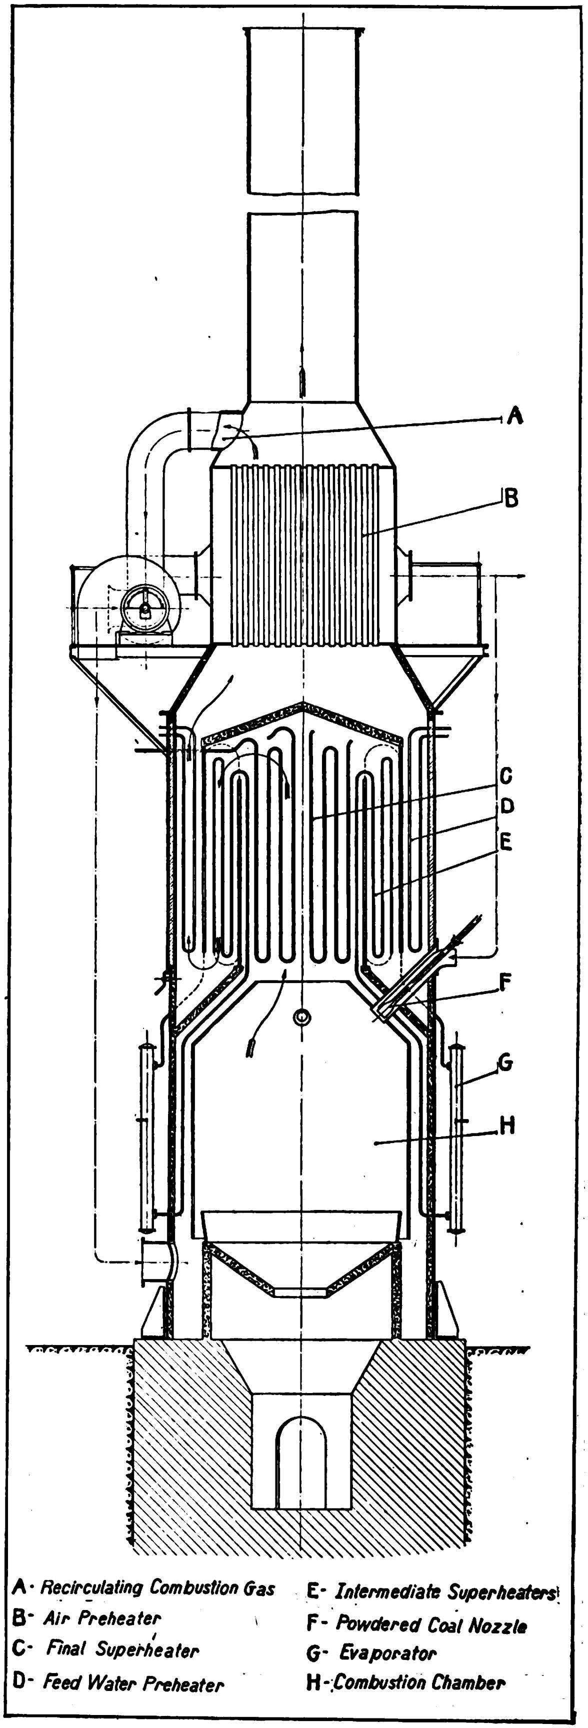

FIG. 11—ELEVATION OF THE BROWN-BOVERI BOILER.

High Pressure Steam Boilers

Statement by A. Borsig, Berlin-Tegel, Germany

Regarding high-pressure steam boilers, there is at our works at Tegel a boiler of 300 sq. m. (3228 sq. ft.) heating surface for a working pressure of 60 ats. (853 lb. per sq. in. abs.) without air preheater, but with a suitable engine. Tests made on this set by Professor Josse of the Charlottenburg Technische Hochschule showed a boiler efficiency of 80.55 per cent, based on the higher heating value of the coal. The high-pressure engine is a tandem compound unit which gave a thermodynamic efficiency of 85.4 per cent.

Two additional high-pressure boilers of 500 sq. m. (5380 sq. ft.) heating surface each and 120 ats. (1707 lb. per sq. in. abs.) working pressure are at present in the course of construction in our shops. Further details of these boilers will be available for publication at a later date.

The Benson Boiler Heat and Power Plant in the Cable Plant Gartenfeld of the Siemens-Schuckert-Werke

Statement by H. Gleichmann, Siemens-Schuckert-Werke

(*From Siemens Zeits., March,* 1928)

The Benson principle employs the critical steam condition (3200 lb. per sq. in. 706.3 deg. fahr.), at which the heat of evaporation is zero, to evaporate the water without change of volume and without the formation of steam bubbles. Therefore, no drums for the separation of steam and water and no tubes for the re-circulation of the water are needed. Re-superheating is necessary in the case of condensing operation and is accomplished either by returning the steam to a superheater in the boiler, by condensing high-pressure steam, or by using the high-pressure steam entering the unit, the temperature of which is lowered by this process.

A simplified steam-water flow diagram of the S.S.W. cable plant is shown in Fig. 12. The steam generated in boiler "a" is supplied to the high-pressure turbine "c" at a throttle pressure of 2570 lb.; the exhaust steam has a pressure of 514 lb. The 514 lb. header supplies part of the steam to the consumer "s," the remaining part to the low-pressure turbine "d." Excess steam, if present, is supplied to the Ruths accumulator "k."

The low-pressure unit has a bleeder point supplying the evaporator "g" to make up for steam used by the consumer "s_3" in which it is contaminated by acids. The vapors leaving the evaporator are mixed with the exhaust steam of the low-pressure turbine in the 78-lb. header, which supplies the consumers "s_2" and "s_3." The condensate from the consumers, excepting "s_3," the condensate of which is wasted due to contamination by acids, and from the evaporator, is collected in a tank "g" from which the high-pressure boiler feed pump "p_3" takes its suction.

The actual arrangements of the system are complicated due to difficult process steam demand conditions. A small part of the process steam is needed at 285 lb. pressure and a temperature of 464 deg. fahr., the remainder at 78 lb. and 464 deg. fahr. The temperature must be very constant to maintain a good quality of the products. About one-third of the condensate cannot be re-used due to contamination. The steam must be delivered at the required pressures and temperatures even when the turbine is not operating. These conditions complicate the system by necessitating regulators and other apparatus which are not otherwise part of the Benson system. The result is the rather complicated flow diagram shown in Fig. 13. The steam leaving the boiler "a" passes a throttle valve "n," which is wide open at full load, the throttling from 3200

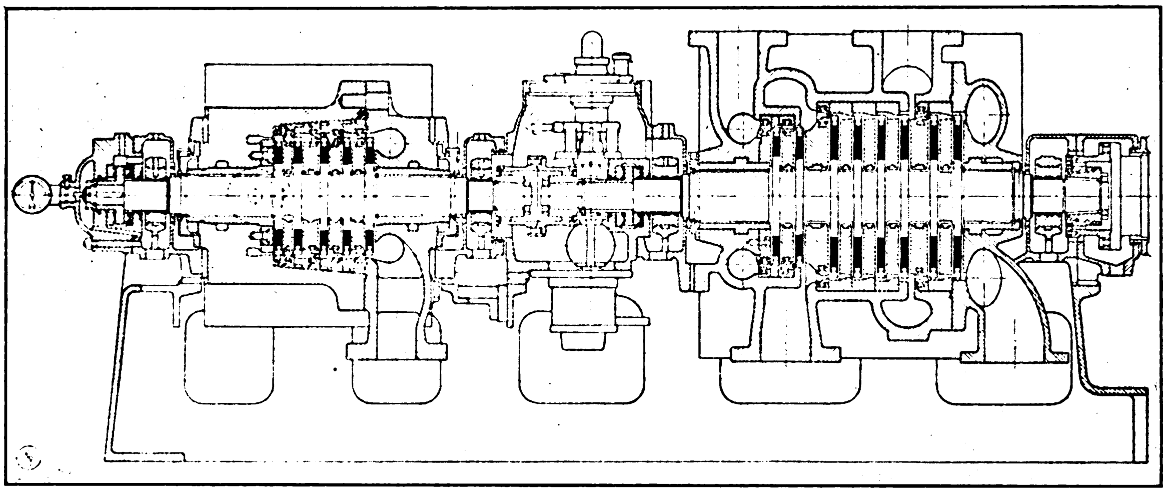

FIG. 14—HIGH-PRESSURE TURBINE AT GARTENFELD.

lb. to 2570 lb. being accomplished in the superheater "b_1." It is intended to connect this throttle valve to the turbine control in later installations. The steam is heated to 842 deg. fahr. in the superheater "b_1" and enters the high-pressure turbine, which is shown in Fig. 14, at this temperature. The turbine governor, acting as overflow regulator, admits all steam generated. The pressure is reduced from 2570 lb. to 856 lb. in the two rows of blades of a Curtis wheel. The spindle and the high-pressure glands, therefore, are exposed only to a pressure of about 856 lb. and a temperature of about 742 deg. fahr. The steam pressure is reduced to about 514 lb. in the remaining stages of the turbine.

When the turbine is not operated, the throttle valve "n_1" is used to reduce the pressure to 514 lb., the steam being cooled in the steam cooler "h_1" which is supplied with water by pump "p_2." Part of the steam taken from the 514-lb. header is reduced to 285-lb. pressure by throttle valve "n_2" and kept at 464 deg. fahr. by the steam cooler "h_2" and is supplied to the consumer "s_1." The remainder of the steam is reheated to 824 deg. fahr. in the reheater "b_2" and admitted to the steam heater "f," in which it superheats the 78 lb. in exhaust steam from the evaporator "g" to 464 deg. fahr. This process reduces the superheat of the steam to about 750 deg. fahr., at which temperature it enters the low-pressure cylinder "d" of the turbine. The exhaust steam of the turbine is admitted to the 78-lb. header. Approximately one-third of the steam entering the low-pressure cylinder is bled at a pressure of about 143 lb. to supply the evaporator. The condensate from this steam, after leaving the evaporator, is returned to the condensate tank. The 78-lb. steam generated in the evaporator is superheated to 464 deg. fahr., as shown above, and supplied to the 78-lb. header.

Since there are considerable steam demand variations in the rubber manufacturing plant, a Ruths accumulator "k" has been installed, which takes steam from the 514-lb. header when the pressure in the 78-lb. header increases, and furnishes steam to this latter header at decreasing pressure in it. Since the temperature of the 78-lb. steam might be lowered to less than 464 deg. fahr. at discharge of the accumulator, the steam leaving the turbine is kept above a temperature of 464 deg. fahr., a cooler "h_3" being normally used to reduce the temperature to that required. At discharge condition of the accumulator, the water supply to the cooler is reduced or eliminated to maintain a final temperature of 464 deg. fahr. in the header. A throttle valve connection "n_3" has been provided to supply the 78-lb. header with steam when the turbine is not operating.

The evaporator raw water is pretreated in the Permutit plant "t" and in the deaerator "l." The condensate from the heaters and consumers, excepting "s_3," is returned to the condensate tank after passing a direct contact heater "i." The steam used in the deaerator and in the heater is taken from the 78-lb. vapors leaving the evaporator. The pump "p_3" takes the condensate, which has a temperature of 300 deg. fahr., from the tank and supplies it to the high-pressure boiler feed pumps at a pressure of 571 lb. This intermediate pressure was selected to obtain a supply of water at sufficient pressure for the steam coolers "h_1" and "h_2." The high-pressure boiler feed pump is a horizontal plunger pump with six pistons and is driven by a d-c. motor for better control. A second pump has been provided for a-c. drive; this pump is a 16-stage, two-cylinder centrifugal pump.

The design of the boiler has been already shown. (See Report of the Subcommittee on Foreign Developments, July, 1928, Pub. No. 278-77). The generation of steam at critical pressure, without circulation and drums, necessitates equal distribution of the water in the parallel tubes and equal heat transmission. The heat needed for heating the water to the critical temperature and part of the superheat is transmitted in the radiation part of the furnace. The furnace, therefore, was arranged as a cylinder, vertical tubes forming the walls. In order to obtain equal resistance in the tube systems, a header has been arranged above the furnace in its vertical center lines from which the water is distributed to the eight tube systems forming the furnace walls. The steam is collected in a header and supplied to four superheater sections arranged in the second pass of the boiler. The exhaust steam of the high-pressure cylinder of the turbine is reheated in the remaining four superheater sections at a pressure of 514 lb.

The forced draft fans supply the combustion air to a circular duct on the foundation from which it passes through the hollow covers of the superheater chambers and air heaters to the inlet of the eight air heaters. After passing downward through the air heaters, in counterflow to the flue gases, it enters a circular duct formed by the air heaters and by the cast iron plates closing the furnace behind the tubes. A small part of the air is passed as primary air to the burners which are located at the top of the furnace. The larger part enters the furnace as secondary air through eight rows of nozzles.

An advantage of the Benson system is the independence from water circulation and drums. A Benson boiler, therefore, can be adapted to any type and form of furnace. In turn, it is necessary to develop furnaces which are adapted to the peculiar type of fuel and combustion selected.

An oil-fired boiler for an hourly capacity of 6600 lb. of steam has been erected in the Technical University at Charlottenburg for test purposes. Designs have been made for chain grate firing and for lignite. The German State Railroads have ordered a fast passenger train locomotive with a Benson boiler from the Maffei Co., at Munich, for test purposes. A small Benson boiler locomotive for exhaust operation is under construction in the United States. A large powdered-coal boiler for 30,000 kw. capacity will be constructed soon.

Foreign Stoker Developments

STATEMENT BY THE AMERICAN ENGINEERING COMPANY, PHILADELPHIA, PA.

The use of multiple retort underfeed stokers in Great Britain and on the Continent is increasing rapidly.

The operation of the new super power station plan in London necessitates the selection of equipment of large steam generating capacity. Chain grate stokers, so far, have been limited to a maximum continuous steam generating capacity of about 100,000 lb. per hr. and, in addition, have not been successful in the use of highly preheated air.

Multiple retort underfeed stokers are installed at the Deptford East and Deptford West plants of the London Electric Companies System. The stokers at Deptford East are typical of those of the best plants in the United States. Fig. 15 illustrates one of a number of similar units at Deptford, 37 tuyeres long and 11 retorts wide. The furnace construction is interesting because of the ingenious method of applying a long stoker, and elimination of a large refractory arch. These units have been in service for some time and have exceeded expectations, giving remarkable fuel burning rates with very low air pressures. Indications are that the fuel burning rates common in the United States can be exceeded with British coals due to their burning characteristics. These units operate with air preheated to 250 deg. fahr. There is an interesting installation in Italy —the Genoa Station of the Milan Edison Company. This station, which serves as a standby, supplementing a hydro-electric system, consists of four boilers each of 19,700 sq. ft. heating surface, fired by 15 retort 37 tuyere Taylor Stokers, as illustrated in Fig. 16. The steam pressure is 425 lb. per sq. in. with a final temperature of 750 deg. fahr. The present boilers are equipped with economizers, but it is planned to use air preheaters in future extensions. The rear wall is protected by a high-pressure waterback, shown in the illustration. Up to the present time it has been impossible to determine the capacity of these units, since the electric output of the station has not yet permitted it.

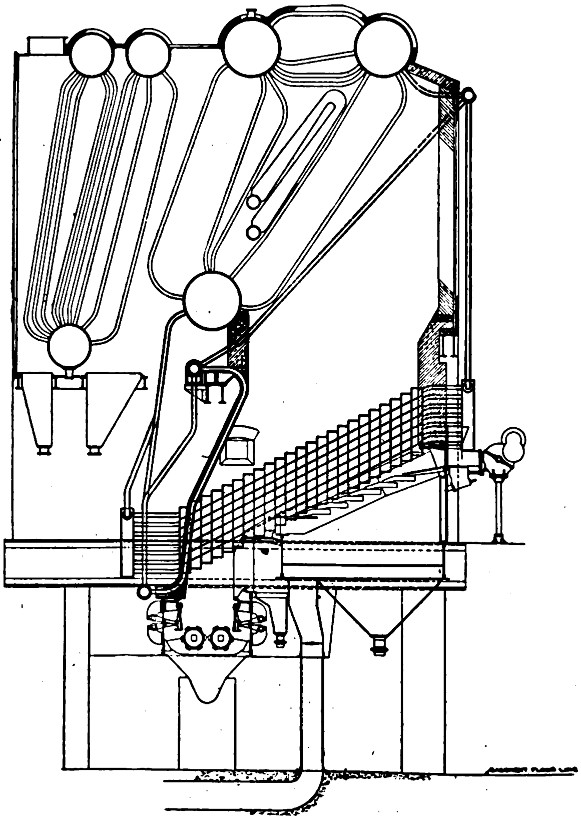

FIG. 15—STOKER AT DEPTFORD EAST STATION.

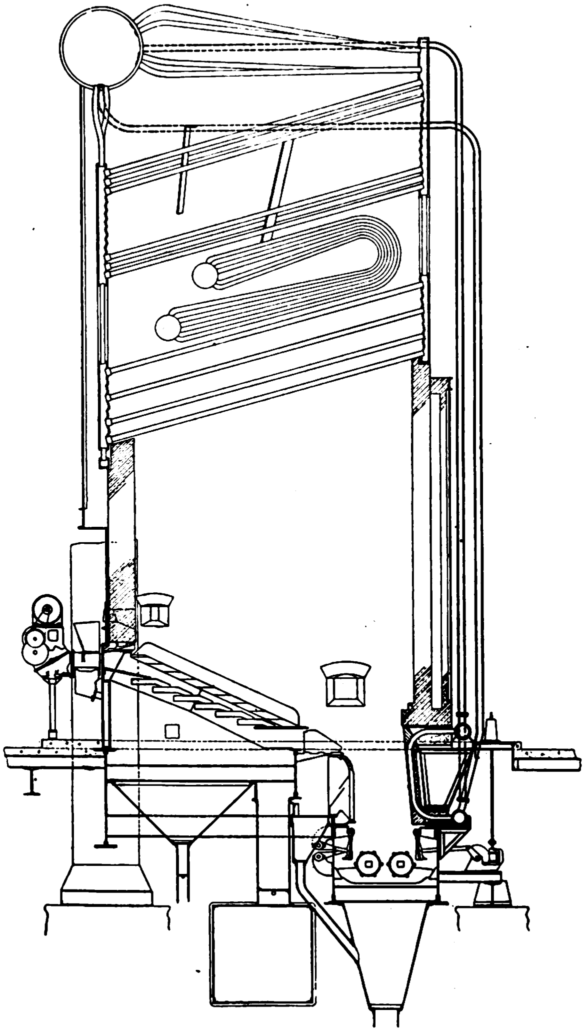

FIG. 16—TAYLOR STOKERS AT GENOA STATION.

"Bewag," in Berlin, Germany, has just placed orders for eight boilers and stokers for the West Side Station in Berlin. These boilers will be 2580 hp. Borsig boilers operating at 410 lb. per sq. in. steam pressure, 800 deg. fahr. steam temperature and feed water at 300 deg. fahr. The temperature of the air for combustion will be approximately 500 deg. fahr. The coal used will have a calorific value of from 11,000 to 14,000 B.t.u. per lb. as fired. The furnace will be cooled on both sides and rear by American Engineering Company type water walls with machined, cast iron blocks bolted to the tubes along the fire line. The stokers will be 20 retorts wide and 49 tuyeres long, giving them the largest projected area of any stokers ever built.

The London Electric Company is rebuilding an old portion of the Deptford West plant and has placed an order for two large boilers and underfeed stokers. These boilers will operate with a steam pressure of 325 lb. per sq. in. and a final steam temperature of 700 deg. fahr. and will be fired by 17 retort, 49 tuyere Taylor Stokers.

The largest steam station in Holland is the "Gurtruidenberg," which is now installing multiple retort underfeed stokers.

That there is a distinct trend toward the underfeed stoker in the large central stations of England, Germany, Holland and Italy is evinced in the above plants in which are represented the latest developments in European power plant practice.

Progress of the Ruths Steam Storage System During the Past Year

STATEMENT BY DR. E. G. RITCHIE, RUTHS STEAM STORAGE, LONDON, ENGLAND

Throughout the world rapid progress is being made in the application of the Ruths Steam Storage System to industrial and power plants. In Sweden the situation is an interesting one because the invention is of Swedish origin, and in its early development was entirely confined to that country. In Sweden almost every factory where the system is applicable now has its Ruths steam accumulator, and from a business point of view the sale of steam accumulators in that country has reached its saturation point. In Germany developments are proceeding apace, while in Great Britain the steam accumulator idea is making great progress.

A Ruths Central organization has been formed in Berlin to undertake research work connected with the subject of Steam Storage, and to act in an advisory capacity for the various Ruths Companies throughout the world.

Several noteworthy engineering developments have taken place in the past year. In Germany railway power stations are now equipped with a Ruths steam accumulator installation, while the system is being applied on a large scale to take care of the peak load in the city of Berlin. It will be recollected that the intention was to make the Klingenberg Station the peak load plant for the whole of the area, the base load being carried by a group of interconnected stations throughout the city. The Klingenberg Station is a "Lopulco" pulverized coal fired station, and represented, when it was erected, the highest development of this system of firing on the Continent. It was later decided, however, to make the Klingenberg Station a base load plant, and to install special turbines and a Ruths Steam Storage Battery at Charlottenburg to take care of the peak load. This decision was only reached after a prolonged discussion as to the best method of solving the problem, the opinions of all interested parties being secured before the matter was finally settled. The accumulator battery in this particular instance comprises 16 vertical tanks 14 ft. 9 in. in diameter by 65 ft. 0 in. high, with a pressure range from 190 lb. to 7 lb. The total weight of water impounded is approximately 5000 tons. The maximum anticipated peak load to be supplied by accumulated steam is 40,000 kw. and the total amount of energy generated during 2½ to 3 hours in the afternoon is approximately 70,000 kw-hr. The peak load turbines are of special types comprising a high-pressure pass-out stage, exhausting steam to the accumulator, which supplies steam to a low-pressure condensing stage operating with an inlet pressure which varies with the pressure in the accumulator. This stage is fitted with a special arrangement of admission nozzles which are brought into operation in succession as the pressure in the accumulator battery falls.

The Charlottenburg steam accumulator installation represents one of the most noteworthy departures in steam electric power generating practice of recent years, and the results obtained will be studied eagerly by power station engineers throughout the world.

Steam storage is a relatively new idea; its progressive development is therefore very largely a matter of education, but there are signs that in all the industrial countries the use of the system is being more and more understood and appreciated.

Electric Boilers and Steam Accumulators

STATEMENT BY C. J. WHARTON

(*From "Science Abstracts" 1276—August, 1928*
World Power, 9 pp. 256-260, May, 1928
Paper read before the Inst. Eng. Inspection)

The author considers the conditions in which it is advantageous to use electricity for generating steam for processes in industrial works, and discusses two types of electric boiler. In the Swedish type, the electrodes enter the base of the vertical cylindrical shell. Steam output and electrical input are varied by raising or lowering vertical tubes round the electrodes. The water level is kept uniform. The German system leads in the circuits at the top of the boiler to hanging electrodes, with piled insulating disks surrounding them. The output of steam is varied by raising and lowering the water level.

The makers guarantee 96 per cent efficiency under commercial conditions. The only losses are due to radiation and blow-down necessary to keep the electric resistance of the water within the required limits. With feed water at 68 deg. fahr. 1 kw-hr. will produce 2.75 lb. steam at 114 lb. gage pressure.

In one case three Lancashire boilers were required to supply a hospital. An electric boiler occupying 49 sq. ft. of floor space, including switchgear and accessories, did the same work as the three boilers. Repairs and maintenance costs are extremely small, and no pitting or scale formation occurs. Ruths steam accumulator is referred to and its use described.

Electric Steam Boilers of 147,000 Kw. Capacity at Gatineau Paper Mill, Canada

STATEMENT BY W. P. MUIR

(*From "Science Abstracts" 1271—August, 1928, Elect. News, Toronto, 37 pp. 55-57, May 15, 1928*)

The boilers are built for power at 6600 volts, 3 phase, and steam at 200 lb. per sq. in. The installation consists of three 42,000 kw. units and one 21,000 kw. Usually one unit using 60-cycle power runs continuously, and a second unit using 25-cycle power supplies the balance or variable load. They are so connected that either frequency can be used. No trouble has occurred due to gas formation in boilers.

The boilers deliver 190 lb. steam to a steam accumulator 12 ft. diameter by 60 ft. long, from which it is drawn at 125 lb. When first installed, as with other new similar plants, quite a lot of dirt was carried back to the feed tank, reducing the purity of the water and necessitating about 25 per cent bleeding. This has now righted itself. The boilers are blown down about 6 or 8 in. every four hours, and under these conditions it has been found necessary to open the boilers every two months only for cleaning. The inner insulators are renewed at the same time. These are of high-grade porcelain, but due to being wet and at high temperature they are found to develop fine cracks in about this length of time. The electrodes are estimated to last five years.

The steam is practically dry saturated, some tests showing only 0.4 per cent moisture.

The New Askania Combustion Control

STATEMENT BY DR. TH. STEIN, A. E. G. BERLIN

On account of the small boiler units used in Europe, the introduction of combustion control demands as cheap and simple equipment as possible. Some useful constructive elements developed for other purposes, were already at hand. The far-reaching use of the Ruths Accumulator in Europe has led to many great improvements in steam regulators. Furthermore, mechanical CO_2 recorders have been so well developed that they could take the place of the more expensive airflow-steamflow recorders for the regulation of boilers. Through theoretical research work on the regulation of combustion processes,* it was possible to decide from the many possible arrangements which was the best. These studies, corroborated by practical tests in 1926, have resulted in the installation of A. E. G.-Askania Combustion Regulators on 79 boilers.

At first it was found that the large dashpots between the regulator and the servomotor as used in numerous hydraulic constructions could be replaced by a small spring attached to the regulator. The spring acts in the same way as the dashpot by producing an opposing force on the regulator, when the regulator leaves its central position, which means when the servomotor is in motion. After all, the dashpot does not do more than produce such an opposing force on the regulator.

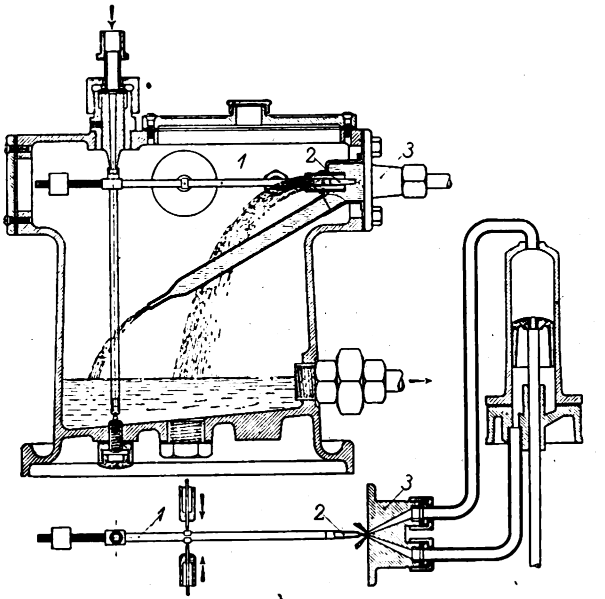
---

* Th. Stein, Regelung und Ausgleich in Dampfanlagen, Berlin, 1926, Julius Springer.

The regulation was divided into three separate processes to avoid incomplete combustion occurring in consequence of quick changes of load before the CO_2 recorder which works with time lag, gets into action. Each process works successively. The load regulator acts only on the speed of the coal feeders by means of a slow-running servomotor. The speed of the coal feeders acts by means of a second regulator with quick-running servomotors on the damper, and supplies an amount of air proportional to its speed. The lack of proportion between the feeder speed and the quantity and changing quality of coal is not so great that incomplete combustion can occur. It has to be specially noted that through its slow-running servomotor the changes of the speed of the feeders are slower than the changes in the consumption of steam. The accumulator capacity of the boiler is utilized through temporary changes of pressure to provide the quantity of steam needed. Therefore, the CO_2 recorder has time to correct the remaining faults every two minutes.

The Jetpipe Combustion Regulator
(See Fig. 17)

The oil enters the bore of the jetpipe at "1," the end "2" of which is movable sideways. Diaphragms act on both sides of the jetpipe, as shown by arrows. A small motion is sufficient to send the oil through the end "2" to the one or the other opening of the distributor "3" whereby the servomotor "4" is moved in either direction.

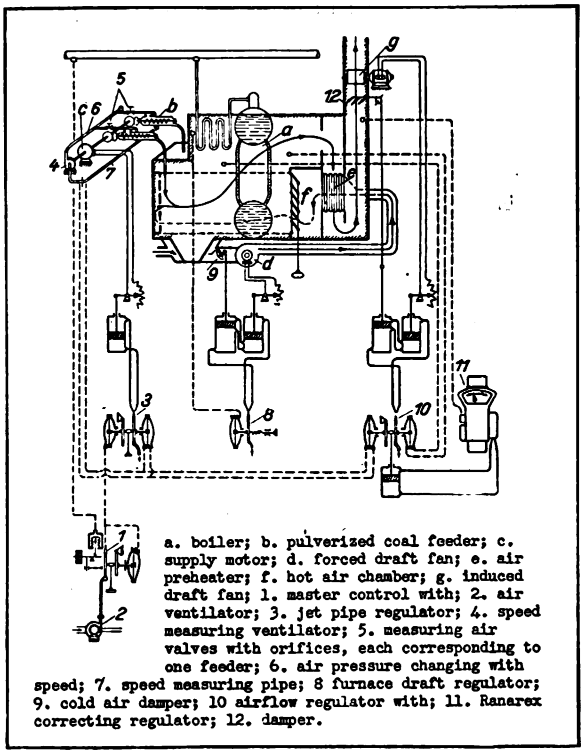


1. jetpipe; 2. end throwing the oil against the, 3. distributor; 4. servomotor.

FIG. 17—JETPIPE REGULATOR.

Regulation of the Speed of Feeders
(See Fig. 18)

The steam pressure acts on the master control "1," where it is balanced against an air-pressure produced by a fan "2." The air-pressure acts on the combustion regulator "3" and moves the resistance of the feeder-motor "c" until the proper speed is reached. The motor "c" drives several feeders at the same speed. The speed is measured by a fan "4." This fan produces an air pressure in the pipe "6" which changes with the speed. Furthermore, the quantity of air flowing through the measuring pipe "7" is in proportion to the number of open valves "5," which are put on and off simultaneously with corresponding feeders. Very small gold orifices are placed in front of these valves. By measuring the airflow in the pipe "7" one records the speed multiplied by the number of the feeders in action as a measure for the quantity of coal fed.



a. boiler; b. pulverized coal feeder; c. supply motor; d. forced draft fan; e. air preheater; f. hot air chamber; g. induced draft fan; 1. master control with; 2. air ventilator; 3. jet pipe regulator; 4. speed measuring ventilator; 5. measuring air valves with orifices, each corresponding to one feeder; 6. air pressure changing with speed; 7. speed measuring pipe; 8 furnace draft regulator; 9. cold air damper; 10 airflow regulator with; 11. Ranarex correcting regulator; 12. damper.

FIG. 18—COMBUSTION CONTROL A. E. G. ASKANIA AT A PULVERIZED COAL BOILER.

Preliminary Regulation of Air

This same measuring air is also transferred to the regulator "10," which acts through the servomotors on the induced draft fan "g" at high loads, and on the damper "12" at low load. At increasing speed of the feeders the airflow increases in the measuring pipe "7," which acts on the left diaphragm, and the servomotors increase the flow of flue gases until the right diaphragm on which the flue gases act is balanced with the left diaphragm, so that the flow of flue gases corresponds to the speed of the feeders. Contrary to the servomotor of the regulator "3," the servomotors of the regulator "10" work very quickly. The oil pipes are connected in special order so that the damper is opened first at low load, and only when its servomotor is at the highest position does it open the oil pipe leading to air damper "9" at low load and the resistance of the forced draft motor at high load.

Correcting Regulation by Ranarex-Recorder

The indicator needle of the Ranarex CO_2 Recorder "11" is connected with a jetpipe which by means of its servomotor gives a correcting impulse on the regulator "10" every two minutes. This changes the proportion between the coal quantity (left) and the flue gas quantity (right). If the Ranarex shows instead of 14 per cent normal CO_2 content only 12.6 per cent it means that about 1.4 ÷ 14 or 10 per cent too much air is furnished by the preliminary regulator "10." The regulator functions in such a way that the proportion of coal and air quantities is changed by 10 per cent. In this way only one single regulation period of two

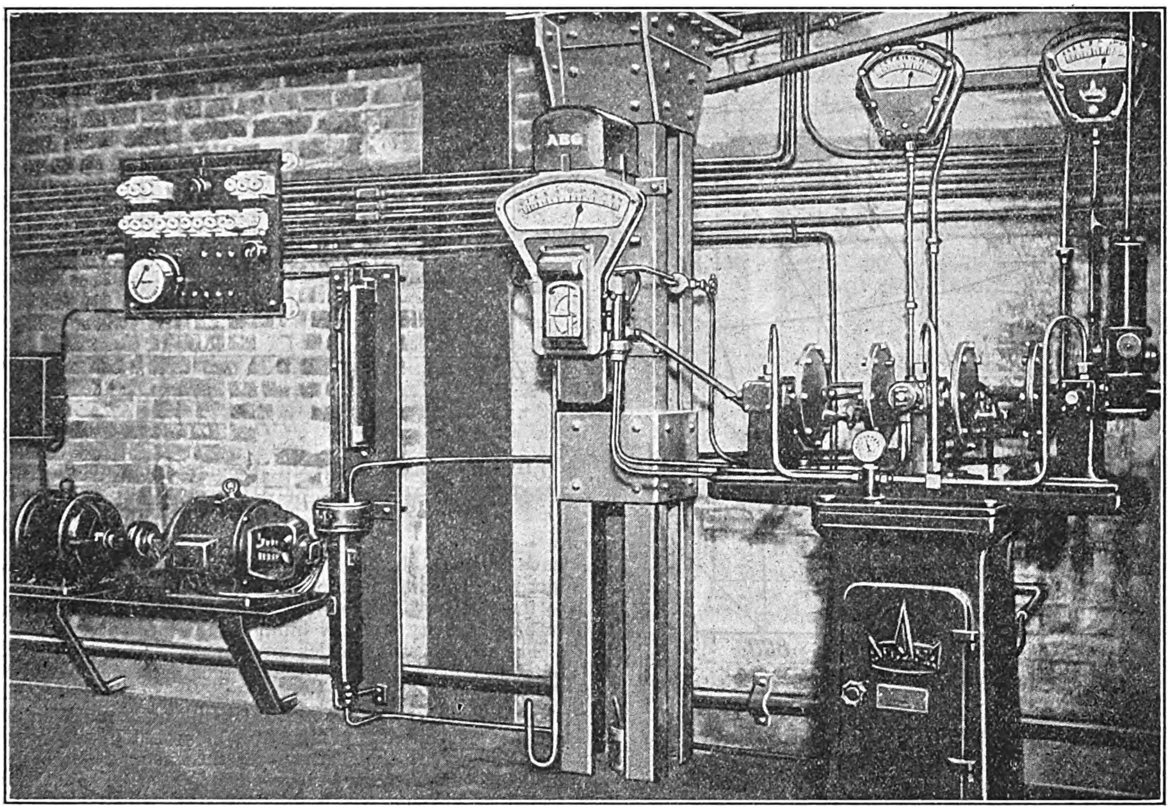


FIG. 19—INSTALLATION OF THE A. E. G. ASKANIA REGULATOR.

minutes in all cases is sufficient for correcting a variation of the CO_2 content.

Fig. 19 shows the whole regulator in a Stettin central station. On the right hand is a box containing the oil pump. The three regulators are installed on top of this box. In the middle of Fig. 19 the Ranarex-Recorder is shown and on the left a Ward-Leonard dynamo with its resistance control by means of which the speed of the feeder motor is regulated.

In the case of boilers with chain grates, the regulation by Ranarex-Recorders is not generally employed, as the speed of the driving motor is a sufficiently good measure for the coal quantity. Also when using boilers without induced draft the grate is enclosed and provided with a regulated damper in order to avoid the discharge of gases from the furnace into the boiler room.

The regulators are so simple, reliable and standardized that they can be adapted to other equipments in power stations. It is therefore proposed to use this standardized apparatus for the regulation of complete steam plants with boilers, Ruths accumulators and turbines.

Efficiencies of High Pressure Turbines

STATEMENT BY DR.-ING. MELAN. SIEMENS-SCHUCKERT-WERKE

(*Siemens Zeit., March,* 1928)

Turbine efficiencies decrease with increasing pressures, due mainly to increase of the leakage and other losses.

Recent investigations made by the S. S. W. showed that the efficiency of a turbine depends on two factors. One of them is the Parson factor:

$$q = \frac{\Sigma u^2}{H_0}$$

i. e., the total of the squares of the peripheral velocities divided by the adiabatic heat drop. The other factor is the "mean steam volume" as expressed by the formula

$$\xi = \frac{P_1 - P_2}{D \times H_0} = \frac{\text{pressure difference}}{\text{Amount of steam} \times \text{adiabatic heat drop}} = \frac{\text{constant}}{\text{Mean volume}}$$

The thermodynamic efficiencies depending on two factors can be shown in a space diagram (Fig. 20). The diagram is correct for complete turbine expansion. Bleeder turbines and "two-pressure turbines" discharging or receiving respectively steam at an intermediate stage must be considered in separate sections according to the varying amounts of steam.

The factor ξ in diagram Fig. 20 increases with higher initial pressure p_1 and decreases with increasing amount of steam D. Turbines with large mean volume are close to the zero point on the ξ axis, turbines with small mean volume farther away. The Parsons factor q is the second axis of the diagram. The ξ formula indicates that the mean volume is determined mainly by pressure drop, amount of steam and adiabatic heat drop and, therefore, can be calculated according to the operating conditions in any individual case.

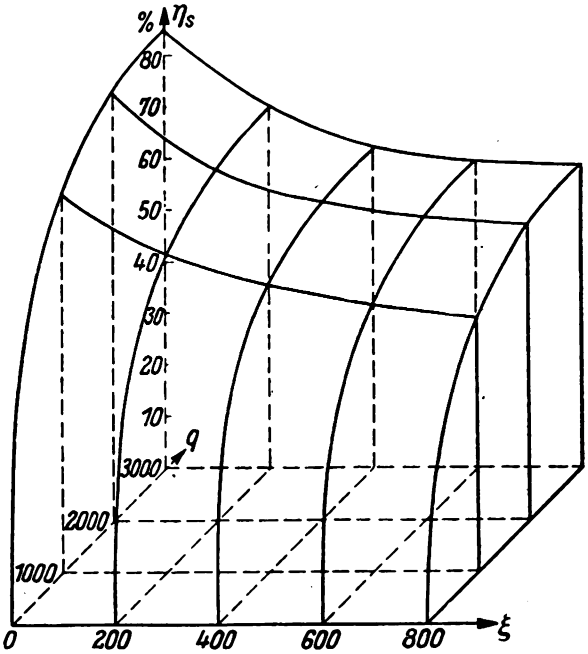
The efficiencies shown in Fig. 20 refer to saturated steam. Correction factors must be used to obtain the actual efficiencies, these factors being larger than 1 for superheated steam and smaller than 1 for wet steam.

The correction factor "f_1" for superheated steam, at a mean superheat "t_m", is

$$f_1 = 1 + \frac{t_m}{1650}$$

The correction factor for wet steam, at a steam quality factor "x_0", is

$$f_2 = \frac{1 + x_0}{2}$$



$$\xi = \frac{p_1 - p_2}{D \cdot H_0} \ldots \; x_1 \approx \text{axis}$$

$$\varphi = \frac{\Sigma u^2}{H_0} \ldots\ldots \; x_2 \approx \text{axis}$$

FIG. 20—SPACE DIAGRAM OF EFFICIENCIES CALCULATED TO SATURATED STEAM.

Recent investigations have shown these factors, which were determined some time ago, are more or less correct.

Numerous test results indicate that the change of efficiency within the range of high pressures, depends on the factors q and ξ. Table III shows the results of a number of tests at different steam pressures and turbine sizes. (The factors q and ξ in the table, as well as other data, are recalculated to the foot-pound Fahrenheit system.) The test results indicate that size of unit does not decide the efficiency; the factor ξ is far more important. The influence of the factor q on the efficiency is approximately identical for the range of from 0 to 800. For comparing calculations, therefore, the efficiency can be reduced to equal q as it has been done for the curve shown in Fig. 21. Table III indicates, for instance, that two entirely different turbines, Nos. 3 and 5, have approximately equal mean volumes ξ though one is operating at a pressure of approximately 200 lb. per sq. in., the other at 728 lb. per sq. in. The efficiencies, therefore, reduced to identical conditions, must be approximately equal, as they actually are. For small ranges of ξ, the efficiencies, calculated to equal conditions, can be shown by the equation

$$\eta = \alpha \beta \xi$$

For small differences ξ, α and β can be considered to be constant. The change of these factors seems to become smaller at high pressures. Further, an upper limit is set to increasing the pressure by the resulting short length of the blades.

Tests made by the S. S. W., together with Escher, Wyss & Co., on a 1400-lb. test turbine in the Nonnendamm Station are very interesting. The turbine received its steam from a Benson boiler, the pressure being throttled from 3200 lb. to the operating pressure. The amount of steam was about 19,600 lb. per hr. The factor ξ was considerably larger than all such figures known before. Accordingly, the thermodynamic efficiency, which was determined to be approximately 62 per cent at ¾ load, was low. These tests have further shown the influence of short blades which increases the influence of the walls on the steam flow, due to the small available cross-section areas. It seems that this turbine capacity is a low limit for this pressure.

The use of still smaller amounts of steam at 1400 lb. or of equal amounts of steam at higher pressures would lower the efficiency still more. An increase of the amount of steam, at otherwise identical conditions, results in larger cross-section areas for the steam flow and in a corresponding decrease of the wall effect; the factor ξ decreases and the efficiency increases correspondingly. This fact is illustrated by turbine No. 6 in Table III, which has been designed for a ten times larger amount of steam than the 1400-lb. unit. The efficiency, at equal conditions, has been increased to 74.2 per cent. Fig. 22 shows the steam rates

at partial loads, according to a report of the Prime Movers Committee. As shown, the steam rate curve is, also, a straight line for high pressure.

The design and construction of the blades is very important at high pressure. The length has a certain influence as mentioned above. All surfaces which are in contact with the steam flow should be machined to decrease friction losses; the ratio of the distance between blades to the width of the blades should be selected to produce the most favorable hydraulic conditions. The steam velocity should be small at high pressures in order to decrease friction losses and to allow more favorable blade dimensions. With large amounts of steam, the simpler reaction blading should be considered in place of the impulse blading.

The graphic method used above makes it possible to compare the available test data on high-pressure turbines on a fair base. Fig. 23 shows the efficiency curves of a condensing turbine for varying throttle pressures at constant throttle temperature (748 deg. fahr.) and at two different

Factor ξ	105.5	103.7	102.9	101.2	95.5	92.2

vacua, according to A. H. Law and S. P. Chittenden, *Engineering,* Vol. 124, p. 610. Curve "a" shows the efficiencies at a vacuum of 93.5 per cent, curve "b" of 97.4 per cent.

The thermodynamic efficiencies are shown for pressures up to 1200 lb. per sq. in. They are correct for uninterrupted expansion, i.e., without reheating and bleeding. As shown, the efficiency goes down from 85 per cent at a pressure of 300 lb. to 78 per cent at 1200 lb.

Table IV shows the efficiency values as calculated to equal conditions; Fig. 24 is a space diagram of the efficiency values in a slightly changed form. The application of the efficiency values taken from Fig. 23 to this space diagram shows the corresponding amounts of steam. Therefore, the understanding that a definite amount of steam belongs to any of the efficiency values.

The result of this investigation is the conclusion that the turbine efficiency at high pressures depends on a certain factor in addition to the Parsons factor. This new factor is determined mainly by the mean steam volume.

Efficiency values based on this conclusion make it possible to determine the efficiency curves for different throttle pressures and amounts of steam as shown in Fig. 25 for amounts of about 55,000 and 165,000 lb. per hr. It is assumed that the throttle temperature is increased with increasing pressure up to a limit of about 800 deg. fahr. The back pressure is assumed to be about 57 lb. per sq. in. abs. The diagram shows that the efficiency decreases at a greater rate at small amounts of steam than at larger amounts. This method can be used to determine the maximum permissible throttle pressure for a turbine at a given amount of steam, and may serve to aid the selection of the steam pressure in designing power plants.

Ljungstrom Steam Turbines

STATEMENT BY S. T. A. L. FINSPONG, SWEDEN

"We have an order from the City Electricity Works of Stockholm at Vartan, for a 27,000 kw. Ljungstrom turbine to be delivered in the summer of 1929. We have also obtained an order from the Government Power service for a 50,000-kw. Ljungstrom turbine at 1500 r.p.m. Its best heat consumption is 11,200 B.t.u. per kw-hr. with initial pressure 242 lb., temperature 750 deg. fahr. and 1.16 in. of mercury exhaust pressure. Details of these units will be available for next year's report.

"Tests were made in November, 1928, on a 13,500-kw. Ljungstrom turbo-generator set installed at the Hamburg Electricity Works, Germany, with the results shown in Table V. These were official acceptance tests of one hour each. In accordance with our practice, the steam leaking from the turbine glands is not included in the turbine water rate."

New Stal Double-Rotation Back-Pressure Turbine

(From "Science Abstracts" 4—January, 1928 *A. S. E. A. J.* 4 *pp.* 98-101, *August,* 1927*)*

This article describes and illustrates a back-pressure turbine, Type DM, of particularly high thermodynamic efficiency and simplicity of construction recently brought out by the STAL Company. It is of the radial double-rotation construction. The blade system contains a smaller number of rings than for condensing turbines, and the outer ring has a smaller diameter.

On account of the comparatively high pressure of the steam in the last state (15 to 150 lb. per sq. in.) a special steel inner housing is placed inside the usual turbine case. The heat insulation is very effective, and also the inlet valve is of ample size for the steam required to be passed. In addition to speed-regulating governors, back-pressure regulators of STAL design are fitted, so that when in parallel with other machines the regulator gives constant back pressure, and the speed governing is put out of action. When the turbine runs alone the speed is governed and the back-pressure regulator thrown out.

Some test results are as follows:

Pressure, inlet lb. sq. in. (abs.)	170.8	202.1	243	256.1
Back pressure, inlet lb. sq. in. (abs.)	59.9	54.6	57	57
Temperature, inlet deg. fahr.	513	524	553	562
Output, kw.	774	1047	1440	1815
Total quantity of steam lb. per hour	33,058	38,094	45,699	57,358
Thermodynamic efficiency, per cent	83.2	85.0	85.2	82.3

The normal output of the turbine is 7500 kw.

Heat Insulation with Aluminum Foil

(From "Science Abstracts" 6*—January,* 1928 *V. D. I.* 71 *pp.* 1395-1400, *October,* 1927*)*

Owing to the very low thermal conductivity of air, the efficiency of a heat insulator depends largely on its porosity and the entrapped air. The porosity also reduces the volume weight of the insulator. The size of the voids is limited, however, by the effect of convection of the air within the cells. The author discusses the influence of the thickness of the air layer on the convection effect and the total heat transmission, and describes experiments carried out to investigate it. The effect of radiation is also considered.

Non-metallic bodies all have radiation coefficients approaching that of "black" bodies. Oxidized metallic surfaces have rather lower values, but polished metallic surfaces have very much lower coefficients, especially in the case of aluminum, for which the figure is about 0.07. This fact is utilized in a form of aluminum foil heat insulation, which is described. The thickness of the foil is less than 0.002 in. and concentric layers are fixed round the pipe to be insulated, separated from one another by rings of insulating material, which also determine the thickness of the air spaces, between 0.4 and 0.8 in. The outer layer may be protected by a sheet-iron casing.

The volume weight of a typical insulation of this kind may be less than 2.5 lb. per cu. ft., i.e., between 5 and 10 per cent of the weight of other insulators. The insulating properties of the new insulation compare favorably with those of the best materials previously used, and various other advantages are described.

The Utilization of Diesel Engines in German Power Houses

STATEMENT BY DR. M. GERCKE, CHIEF ENGINEER, MASCHINENFABRIK AUGSBURG-NURNBERG, A. G.

Small and medium-size Diesel engines, principally of the single-acting four-stroke type, are utilized in thousands of units for driving the electric generators of many power houses all over the world. The high thermal efficiency of the Diesel engine and its high standard of mechanical perfection were responsible for the speedy introduction of this internal-combustion engine in the electric installations where formerly only steam and gas engines were operated.

For small and medium-size engines the single-acting four-cycle type, with airless fuel injection, is holding the field; single-acting two-cycle engines began to compete seriously some time ago with the four-cycle type by lower initial prices, though the fuel consumption of the four-cycle type is somewhat lower than that of the two-cycle type.

For electric power house service two different types of Diesel engines must be considered:

(1) For continuous operation—the total load, base load and peak load together being covered by the same engines;
(2) For peak load service and for stand-by purposes exclusively, i.e., for short-time operation, the base load being borne by steam or water power plants.

For purpose (1) high thermal efficiency and long life are essential, besides, of course, continuity of operation. As a rule heavy and expensive engines with low and medium speeds are supplied for this service, mainly single-acting four-stroke and single and double-acting two-stroke engines of different types.

For purpose (2) Diesel engines of another special design had to be constructed which are characterized by the following features: (a) Low first cost; (b) perfect safety of operation; (c) simple operation with quick starting and loading. High thermal efficiency and long life are not the predominant considerations.

These requirements lead to light construction and the application of extra high quality materials, high rotative speed, high mean effective pressures and high piston speed.

For outputs between 1000 and 2000 kw., mainly high-speed, single-acting, four-stroke engines with airless fuel injection are used, and their superiority is unchallenged. For medium-size units up to something like 3000 kw. single- and double-acting two-stroke engines are in keen competition regarding first cost, fuel consumption and floor space; if high-powered units are wanted, only double-acting, two-stroke engines with speeds between 200 and 300 r.p.m. are successfully employed. The high-powered Diesel engines up to 10,000 kw. and over are exclusively double-acting, two-stroke engines; single-acting units being only constructed occasionally for a maximum capacity of more than 3000 kw. Examples of Diesel engines, classified according to this scheme, are shown in the illustrations, viz:

Fig. 26—Plant of a chemical concern for practically continuous full-load service, with 7 single-acting, four-stroke engines of 1000 kw. each, and one double-acting, two-stroke engine of 3800 kw., all of them running at slow speed.

Fig. 27—A high-speed, single-acting, four-stroke engine of 1000 kw. with airless fuel injection, installed in the peak-load and standby station of the municipal power house of Kottbus, which is operated as a substation fed by the Berlin Municipal Electric Works (BEWAG).

Fig. 28—A high-speed, double-acting, two-stroke Diesel engine of 7500 kw. net with airless fuel injection on the test bed; two units of this capacity are employed for the peak-load and standby installation of the substation Hennigsdorf near Berlin, owned by the Maerkisches Elektrizitatswerke A. G.

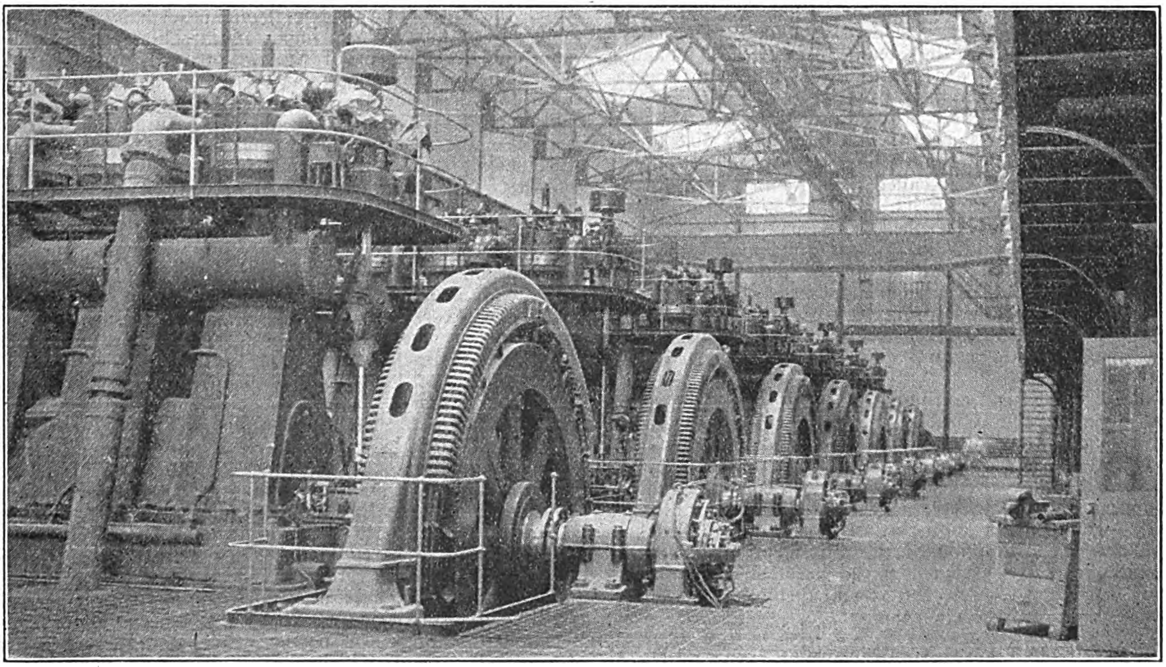

FIG. 26—PLANT OF A CHEMICAL CONCERN FOR PRACTICALLY CONTINUOUS FULL LOAD SERVICE.

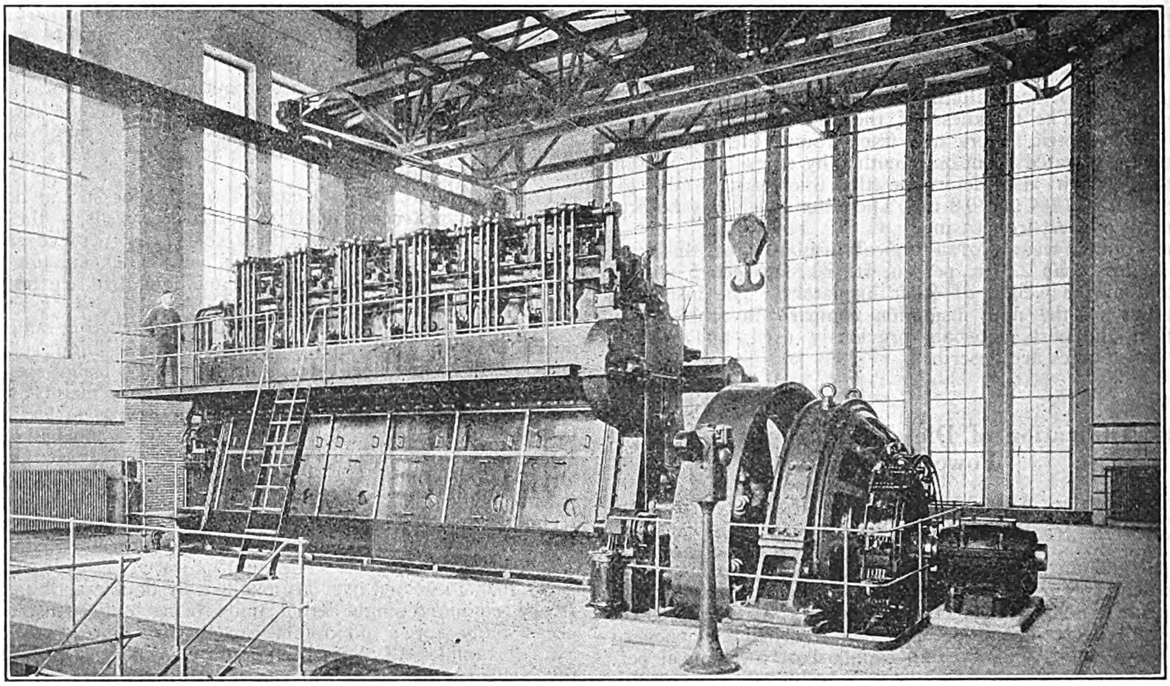

FIG. 27—A HIGH-SPEED SINGLE-ACTING FOUR-STROKE ENGINE OF 1000 KW. WITH AIRLESS FUEL INJECTION.

Fig. 29—The largest Diesel engine in the world, a double-acting, two-cycle engine of 10,000 kw., installed in the Neuhof power house of the Hamburg Electric Works, as a peak-load and standby unit.

The engines, Fig. 26 to 28, were constructed by the Maschinenfabrik Augsburg-Nurnberg A. G. Augsburg Works (M. A. N.), and engine, Fig. 29, by the Hamburg shipyard of Blohm & Voss on the basis of the patents and with the cooperation of the M. A. N.

Comparing the technical and economical features of the Diesel engines with steam installations of the same capacity and the same operating conditions, the following facts may be emphasized.

Regarding safety of operation and reliability, both types of prime movers may be considered as equal. The Diesel engines are superior to the steam installations, including boilers, condensers and accessories, in simplicity of operation, in constant consumption of fuel per kw-hr. and in floor space occupied—this last point, at least, for a total capacity of the power house of less than about 30,000 kw.

The economical comparison of both types of prime movers must be based upon the so-called time factor of the maximum demand or load factor, i.e., on the ratio of utilization which can be practically reached per year. It is clear that a high load factor results in a great influence of the fuel account upon the total expenses of the power production, the capital costs being of minor importance. On the other hand, peak-load and standby service cause a very small load factor; therefore, the influence of the fuel consumption cost is small, but the capital costs must be reduced to a minimum.

Calculating the heat consumption of a high-class steam turbine plant with favorable circumstances of operation (high pressure, high superheat and good vacuum), an average of 4200 k. cal. per kw-hr. (16,700 B.t.u. per kw-hr.) may be considered as a conservative figure, compared with a consumption of 2600 k. cal. per kw-hr. (10,350 B.t.u. per kw-hr.), secured by a high-class Diesel engine, all losses and the power consumption of the auxiliaries included. If the initial costs are assumed to be practically equal, the ratio of equal fuel costs for steam turbines and Diesel engines results from the comparison:

$$\frac{4{,}200}{7{,}200} \times \text{price of coal per kw.} = \frac{2{,}600}{10{,}000} \times \text{price of Diesel oil per kg.}$$

with coal of 7200 k. cal. per kg. (13,000 B.t.u. per lb.) and Diesel oil of 10,000 k. cal. per kg. (18,000 B.t.u. per lb.). These are compared to find the same fuel costs per kw-hr. From this formula results the ratio:

$$\frac{\text{price of coal}}{\text{price of Diesel oil}} = \frac{2{,}600 \times 7{,}200}{4{,}200 \times 10{,}000} = \frac{1}{2.24}$$

This means that the economy of the Diesel engine is equivalent to the economy of the steam turbine, calculated for full load and without waste heat utilization, if the price of 1 ton of Diesel oil is not higher than the price of 2.24 tons of coal. As a matter of fact in Germany imported Diesel oil is now 4.5 to 5.5 times dearer than coal; on the other hand, the production of Diesel oil in Germany is very small and only of limited local importance. This fact is handicapping the development of the stationary high-powered Diesel engine for continuous service in German electricity plants with good load factors. For smaller outputs up to a couple of hundred kilowatts, conditions are naturally different. In this case the Diesel engine competes not against the steam turbine but against the steam engine and other power generators. If little exhaust steam is required for heating purposes, then the Diesel engine gets the preference in Germany. Also for large outputs there are special cases where the high fuel charges of the Diesel engines are balanced by unfavorable water supply for the boilers and condensers of the steam installations, or by bad transport conditions for coal. In these cases the Diesel engine is superior to the steam plants, even if the fuel is much more expensive.

The more or less perfect utilization of the waste heat, in the form of low-pressure steam, hot water or hot air, may furthermore change the economical balance between the two types of prime movers in individual cases.

For peak load purposes the situation is different, as the Diesel engine has the advantage of quick starting, i.e., of carrying load within a few minutes without previous fuel consumption, preheating or other preliminaries.

In case of necessity, the peak load Diesel engines can also be used to carry load besides that required for peak load purposes, because they are independent of the base load units—a big advantage in comparison with such secondary peak load installations as Ruths steam accumulators, water accumulator tanks for power water storage and batteries for direct current, which are all dependent upon the base load installations and the power transmission system, and

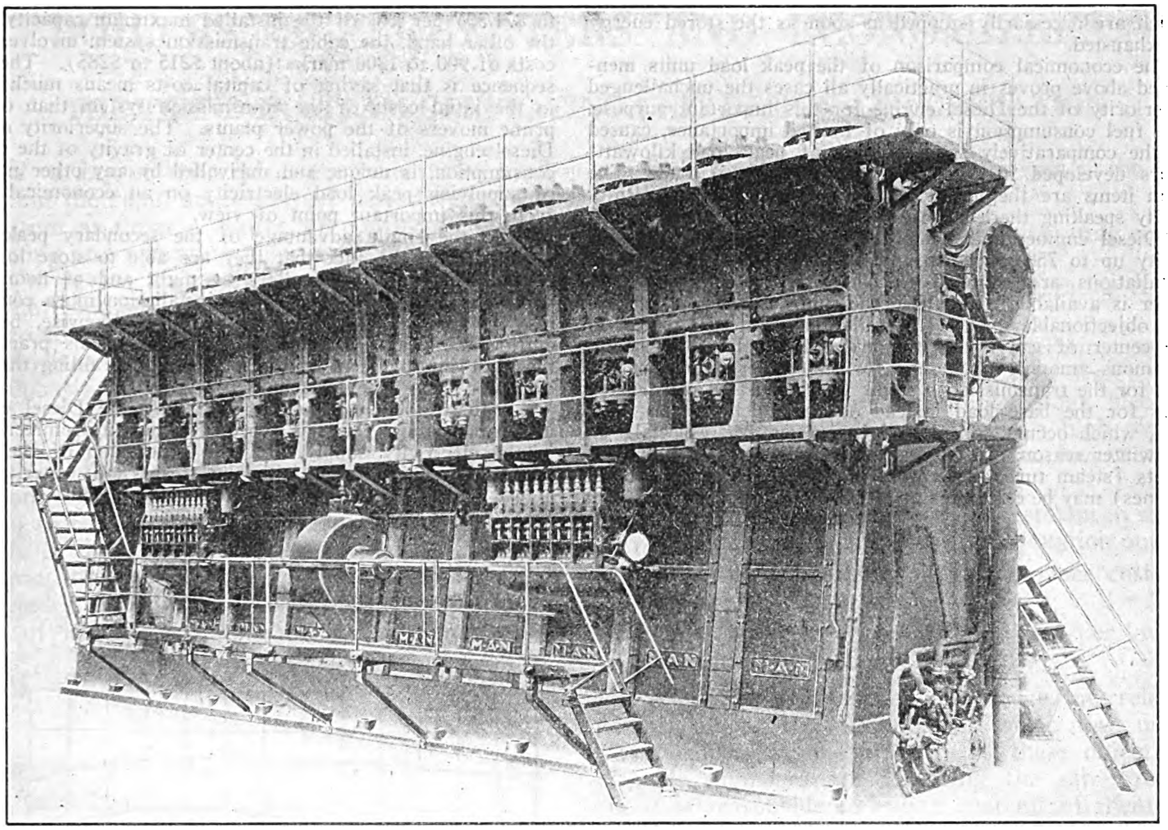

FIG. 28—A HIGH-SPEED DOUBLE-ACTING TWO-STROKE DIESEL ENGINE OF 7500-KW. NET WITH AIRLESS FUEL INJECTION ON THE TEST BED.

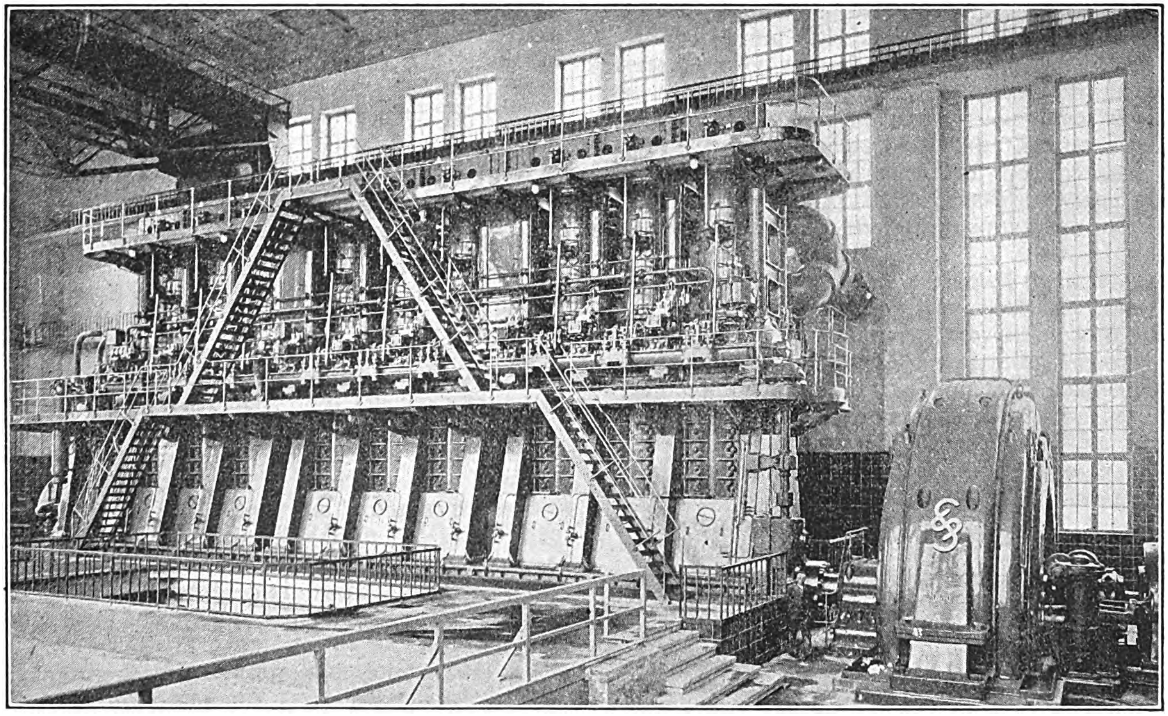

FIG. 29—THE LARGEST DIESEL ENGINE IN THE WORLD. 10,500 KW.

which are necessarily stopped as soon as the stored energy is exhausted.

The economical comparison of the peak load units mentioned above proves in practically all cases the unchallenged superiority of the Diesel engine for this important purpose. The fuel consumption is only of limited importance, caused by the comparatively small amount of peak load kilowatt-hours developed in comparison with the base load. The main items are the initial costs and fixed charges. Practically speaking there is no difference between the first cost of Diesel engines and steam turbo-generators of equal capacity up to 7500 kw. per unit or thereabouts. But steam installations are confined to places where much cooling water is available, and where the flue gases and ashes are not objectionable. Diesel installations can be erected in the center of gravity of the area of supply, thus saving enormous amounts of money for the cables, transformers, etc., for the transmission systems which must be constructed only for the base load instead of the much heavier peak load, which occurs only 2 to 3 hours per day, especially in the winter season. In Germany the first cost of heat power plants (steam turbo generators with boilers, etc., or Diesel engines) may be calculated at 200 to 300 marks (about $47.50 to $71.50) per kw. of the installed maximum capacity. On the other hand, the cable transmission system involves first costs of 900 to 1200 marks (about $215 to $285). The consequence is that saving of capital costs means much more in the intial costs of the transmission system than of the prime movers of the power plants. The superiority of the Diesel engine, installed in the center of gravity of the power consumption, is unique and unrivalled by any other method of supplying peak load electricity on an economical scale from this important point of view.

Even the single advantage of the secondary peak load suppliers, i.e., the fact that they are able to store lost energy during the load valleys at night and at noon, and make the load of the base load installation more constant, may be claimed for the Diesel engines likewise, because cutting the peaks of the load diagrams means practically the same improvement of the load factor as filling the load valleys of the base load units.

All these facts together explain why the Diesel engine in German power plants is expected to play a prominent rôle in the electricity supply, viz., the production of the peak load kw-hr. in parallel with the steam and water power plants, which supply the base load kw-hr. in bulk.

BOILERS, SUPERHEATERS AND ECONOMIZERS

THE TREND IN STEAM GENERATING UNIT DESIGN AND OPERATION

The variety of boiler plant equipment now available and the rapid succession of new developments constitute at times a source of confusion, both to designing and operating engineers. It seems worth while to review and evaluate some of the most recent developments and to attempt to relate important trends of design where possible, to certain definite objectives.

Emphasis of much of the work done by designing and operating engineers during the interval from 1918 to 1925 was placed on improvement in the overall efficiency of the steam generating unit. Publication in January, 1925, of the results of tests made on one of the four 30,600-sq. ft. pulverized fuel fired boilers in the Lake Shore Station of the Cleveland Electric Illuminating Co. served as a milepost of progress in boiler plant design. These tests, the results of which are shown in Fig. 1, demonstrated the feasibility of transfer of heat from coal to water and steam, with a total loss varying from 8 to 10 per cent of the total heat in fuel, for an operating range from 65,000 to 250,000 lb. of steam output per hour. One 22-hr. test, with a total evaporation of 131,400 lb. per hour, showed an overall efficiency of 92.9 per cent. Operation during these tests, resulting in these extremely high efficiencies and in the reduction of the temperature of flue gases to values ranging from 174 to 318 deg. fahr. left a negligible margin for future improvement. While it was realized that the delivery of water to the economizer at temperatures ranging from 125 to 157 deg. fahr. during these tests was a contributing factor which made possible the high overall efficiencies, this fact did little to minimize the value of the achievement.

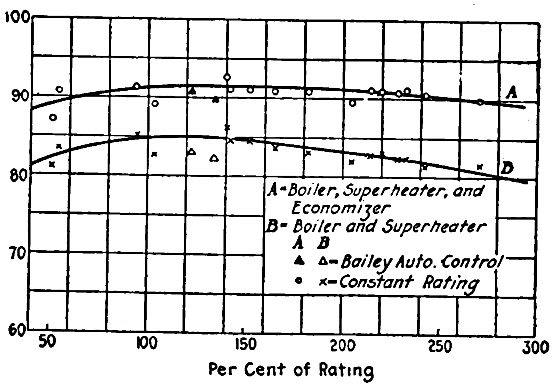

FIG. 1—BOILER TESTS, LAKE SHORE STATION. CLEVELAND ELECTRIC ILLUMINATING CO. (JOHN WOLFF, MECH. ENG., JAN., 1925).

During the last four years, a major portion of the work done by designing and operating engineers has been dominated by a desire to reach the following objectives:

1. Successful operation of steam generating equipment with higher pressures.
2. Successful operation of steam generating equipment with higher temperatures.
3. The modification of steam generating equipment so as to allow heating feed water to a relatively high temperature by stage bleeding and still permit of maintaining a high overall efficiency of transfer of heat from fuel to steam and water.
4. To effect a reduction in the investment in steam generating equipment per kw. of station output.
5. To effect a reduction in maintenance cost per kw-hr. of station output.
6. To effect a reduction in labor cost per kw-hr. of station output.

These six objectives are very much interrelated. Almost all of the development work now under way is aimed at one or more of these objectives. Not all engineers are following the same roads, but it is reasonable to expect that all of them are dominated by a desire to reach the same reasonable objectives.

High Steam Pressures

Operating pressures have been pushed higher and higher during recent years. Two trends have developed. A number of engineers have been willing to do pioneering work and to go to the use of higher pressures even though this might mean the use of generating equipment quite special in its character. Much of the steam generating equipment designed for pressures in excess of 450 lb. has been special. Engineers of a second school of thought have been willing to go to only those pressures which permit the use of steam generating equipment of fairly standard characteristics.

As manufacturers have perfected their shop processes and tools, and as better materials have been made available for their use, they have been able to increase the upper limit of operating pressure for which equipment of fairly standard characteristics can be designed. For example, there have been successive increases from 385 to 425, to 450, to 488, and more recently to approximately 600 lb., in the maximum operating pressure for straight-tube cross-drum boilers of fairly conventional design, using 4-in. tubes. Not many years ago the maximum pressure for which Stirling boilers or other bent tube boilers of similar type having tubes 3¼ in. in diameter could be purchased, was of the order of 410-lb. gage. At the present time bent tube boilers having riveted drums and of fairly conventional design can be purchased for an operating pressure of 450-lb. gage.

Publication No. 289-75 Serial Report, Prime Movers Committee.

Independent analyses made by a number of engineers have demonstrated that an increase in pressure, as long as it is accompanied by no marked change in the characteristics of the equipment or the size of the steam generating units and the turbine-generators, produces two results:

1. A reduction in fuel consumption per kw-hr. of station send-out.
2. A reduction in the investment per kw. of station send-out.

There has accordingly been a very definite trend in connection with much of the recent steam station construction to use the highest pressure for which steam generating equipment of fairly standard characteristics could be purchased at the time of design.

It is coming to be well recognized that the tendency toward caustic embrittlement of boiler drums is very much more marked as the operating pressure and the temperature of the water are raised. Accelerated embrittlement tests made in the laboratory have shown that for standardized conditions flange steel has cracked in 720 hr. for 100-lb. steam pressure, in 30 hr. for 500-lb. pressure, and in 10 hr. for 1000-lb. pressure. This greater tendency toward embrittlement incidental to higher operating pressures has introduced a problem in many stations which, with relatively good water conditions and lower operating pressures, would have never needed consideration as an important operating problem. Two solutions present themselves:

1. The use of effective inhibitors. The maintaining of a proper ratio of sulphates to carbonates by the injection of sulphuric acid into the feed water is a satisfactory solution, but the increasing amount of sulphates which must be added to the feed water for higher pressures makes this solution far from desirable. Laboratory research work has indicated that relatively small amounts of phosphate will serve effectively to inhibit embrittlement. It is hoped that actual operating experience will prove the effectiveness of the phosphate treatment.
2. The use of forged or hammer-welded boiler drums rather than riveted drums probably offers a solution for the problem of caustic embrittlement. In general, it has been the practice to use forged drums for operating pressures in excess of 700 lb. One company has, however, fairly definitely standardized on the use of forged or hammer-welded drums for pressures in excess of 450 lb. One of the operating companies has ordered during the last two years a number of boilers having hammer-welded drums. Presumably the thought lying back of the use of welded construction is elimination of the possibility of concentration of solids in the seams and the corresponding hazard of embrittlement.

In connection with riveted drums, the practice of inside caulking of seams has been adopted almost universally. The limitation in operating pressure for which bent tube boilers having riveted drums can be designed has mainly existed in connection with the drums and, as pointed out earlier, has served to limit the maximum pressure for a time to 410-lb. and more recently to 450-lb. gage. In connection with straight-tube cross-drum boilers, the limit in pressure has been in connection with the headers. The practice has been adopted in a great many cases of designing the drums for a somewhat higher pressure than the headers and the tubes, in order to allow for an appreciable amount of pitting in the drum without the necessity of derating the operating pressure of the boiler.

The rather general adoption of operating pressures in excess of 400 lb. has involved the almost universal discarding of round gage glasses and the use of high-pressure gage glasses having flat glass windows. The problem of satisfactorily illuminating the flat glass windows has not been satisfactorily solved for the majority of installations. It is hoped that development work now under way will lead to a satisfactory solution of this problem.

A most valuable development has been the use of a standard recording flow meter, calibrated to record the head of water in the water column and so serving as an accessory to the high pressure gage glass recording the level of water in the boiler drum.

Higher Steam Temperatures

There has been a very general trend toward the use of higher steam temperatures. A survey of operating practice in the United States, as outlined later in this report, shows that the average operating temperature for the stations considered is 640 deg. fahr., and that in normal operation a temperature of 750 deg. fahr. is seldom exceeded. This is perhaps accounted for by the fact that one of the leading manufacturers has taken the stand that a steam temperature of 750 deg. should not be exceeded, unless superheater tubes of very special and quite expensive alloy metal are used. A second manufacturer, however, in a statement submitted to this Committee in 1926, stated that he is willing to offer superheaters designed for a steam temperature of 800 deg. using plain steel tubes.

There is a definite desire on the part of operating and designing engineers to go to the use of still higher temperatures. There are three incentives justifying such use:

1. An increase in temperature will result in a material reduction in fuel consumption. If the increase in steam temperature can be effected without the adoption of radical changes in design, it is one of the easiest ways of effecting an appreciable fuel saving.
2. Independent studies made by a number of engineers have shown that higher temperatures will result in a reduction in the investment, assuming that no marked change in the construction of the steam generating unit is involved. (The use of special and expensive alloy metal in the superheaters or the use of a single stage of reheating with steam returned to the boiler house, this being the equivalent of increase in

steam temperature at the turbine throttle, may be classified as marked changes.)

3. An increase in temperature at the turbine throttle with the corresponding reduction in moisture in the lower stages of the turbine, results in very material reduction in the amount of erosion in the lower stages of the turbine, reducing the cost of one of the largest single items of turbine maintenance and increasing the number of hours per year that turbines are available for service.

The expressed willingness of two of the manufacturers to build straight-tube cross-drum boilers with tubes 4 in. in diameter, and in other respects of fairly standard construction for operating pressures in the neighborhood of 600 lb., has increased the importance of considering higher steam temperatures. With 600 lb., 800 deg. fahr. steam delivered to the turbine throttle, the percentage of moisture in the steam passing through the last row of turbine blades and expanding to a 29-in. vacuum would be no higher than with 375 lb., 700 deg. fahr. steam delivered to the turbine throttle, and also expanded to 29-in. vacuum.

The fact that the use of temperatures ranging from 800 to 850 deg. holds promise of a reduction in fuel cost, a reduction in investment and corresponding fixed charges, and a reduction in maintenance, serves as a very definite incentive for intensive development of equipment for operation at these higher temperatures.

It appears that the most serious obstacle standing in the way of the general adoption of higher temperatures is the fear that there will be a rapid deterioration in the superheater elements. Two problems present themselves in connection with the superheater elements:

1. Due to the transfer of heat through the wall of the superheater element, the metal temperature is appreciably higher than the steam temperature, and it is the temperature of the metal which determines the rate of deterioration.
2. Due to the transfer of heat through the wall of the superheater element, the outer skin is at a higher temperature than the inner portion of the wall, resulting in the setting up of temperature stresses which, under certain extreme conditions, may be of the same magnitude as the stresses from the steam pressure.

The solutions for these two problems lie along several different lines. Anything that can be done to reduce the differential between maximum steam temperature and the maximum temperature of the metal will be beneficial. In this connection the problem of superheater design as it now stands, closely parallels the design of electrical machinery, the aim being the same in both cases to limit hot spot temperatures as much as possible. A decrease in the average rate of heat transfer and particularly in the rate of heat transfer at the outlet end of the superheater; an increase in the steam velocities through the elements; a reduction in the mean internal hydraulic radius of the superheater elements; the introduction of saturated steam into the portion of the superheater in contact with the hottest gases; the maintaining of high steam velocities in the elements and low steam velocities in the headers, so as to insure uniform distribution of steam between all elements in parallel; the elimination of laning of the gases through the superheater; and the elimination of secondary combustion in the superheater pass, are all effective in the reduction of the differential between the highest metal temperature and the steam temperature at the superheater outlet. A reduction in the maximum rate of heat transfer for any portion of the superheater, and particularly for the area adjacent to the superheater outlet, will serve as the most effective means of reducing temperature stresses.

The success which has been attained in the operation of radiant superheaters over a period of three or four years, with rates of heat absorption in the neighborhood of 45,000 B.t.u. per hr. per sq. ft. (at final temperatures of from 700 to 750 deg. fahr.) seems to point the way to the design of superheaters for operation with steam temperatures from 800 to 850 deg. fahr. The rather successful operation of these radiant heat superheaters must be viewed in the light of their high rates of heat transfer, the fact that the elements are of plain forged steel, and that the elements have a wall thickness of approximately ¾ in. Conditions of operation are such as to result in relatively high metal temperatures and also in relatively high temperature stresses. In contrast, the use of convection type superheaters, shielded from the furnace by ten rows of boiler tubes and designed with very liberal areas, will permit of delivering steam at a temperature of 800 deg. fahr. or higher, and a maximum heat transfer rate of approximately 5000 B.t.u. per hr. per sq. ft. of surface.

It would appear that it is possible, in connection with a very liberally designed convection type superheater, using tubes having a wall thickness of No. 10 B. W. G. (0.134 in.) and delivering steam at a temperature of 800 deg. fahr., to limit both the maximum metal temperature and the temperature stresses to lower values than exist in connection with installations of radiant heat superheaters, which are now in successful operation, delivering steam at a temperature from 700 to 750 deg. fahr.

It is not generally realized either by designing or operating engineers that, in the interests of good design and safe operation, a high-pressure drop through the superheater must be accepted. This is particularly true in connection with the superheaters of boilers which must operate successfully through a wide range of load. In connection with an installation of this type, a pressure drop of 40 lb. through the superheater at maximum load is not unreasonable. To insure proper steam distribution, safe design indicates that not more than 15 per cent of the pressure drop should be in the headers.

It must be recognized that the acceptance of a convection type superheater having low rates of heat transfer involves a greater variation in steam temperature from low load to maximum evaporation than will be the case for interdeck superheaters, or for the combination of a convection type superheater in series with a radiant type superheater. The steam temperature characteristic can be flattened out to some extent by the use of very high steam velocities through the superheater elements at maximum load. It seems probable that the assurance of freedom from trouble which we may reasonably expect from a convection type superheater designed along the lines outlined above, the ability to go to higher temperatures, the possibility of the use of steam pressures of the order of 600 lb. without the need for reheat, and the simplification in design of the boiler unit itself, may serve as such powerful incentives that they will offset the greater variation in steam temperature from low to maximum load.

Maintenance of High Overall Efficiency with Increased Temperature of Feed Water Delivered to the Steam Generating Unit

The desire on the part of designing and operating engineers to avail themselves of economies incident to the use of the regenerative cycle has led very generally to an increase in the temperature of feed water delivered to the steam generating unit. This condition has in many cases made necessary radical changes in the design of the steam generating unit in order that the overall efficiency might be maintained with feed water temperatures ranging from 350 to 425 deg. fahr. In most cases the result has been the installation of an air heater or the combination of an air heater and economizer. Until five years ago there were many new installations of boiler units without either air heaters or economizers. For the larger stations, engineers were fairly evenly divided into two groups: Those who favored the use of high boilers or their equivalent and no economizers; and those who favored the use of fairly low boilers with economizers. The simultaneous introduction of the regenerative cycle and the use of air heaters, together with the desire in most cases to effect a reduction in coal consumption, has divided boiler installations into three classes:

1. A comparatively low boiler or its equivalent, and an economizer.
2. A comparatively high boiler or its equivalent and an air heater.
3. A comparatively low boiler or its equivalent, followed by an economizer and an air heater.

A related matter which has affected the choice and the proportioning of the air heater has been the air temperature which operating engineers have found desirable in connection with different types of fuel burning equipment.

Of the fifteen new power stations which have recently gone into operation, or are now in the course of construction, there are only two in which neither air heaters nor economizers are installed. In one of these two stations plans are made for the future installation of air heaters and economizers.

Reduction of Investment in Steam Generating Equipment Per Kw. of Station Output

This subject may be divided into two phases:

1. The reduction in investment per unit of installed capacity.
2. The reduction in the amount of spare capacity.

Advances in the design of fuel burning equipment have been such as to permit of burning a greatly increased amount of fuel in a single boiler unit. The development of fuel burning equipment was brought to a point five years ago so that it no longer served as a limitation to boiler output, the real limitation being in the ability of furnace refractories to stand punishment. The air cooling of furnace walls provided some relief. The use of water-cooled furnace walls served, however, as the real solution for the problem and definitely eliminated refractories as a limitation to boiler output.

The introduction of water-cooled furnace walls was surrounded with a certain amount of misunderstanding. It was claimed by some engineers that the use of water-cooled furnace walls would result in an increase in the overall efficiency of the boiler unit as a result of the absorption of a larger percentage of the total heat by radiation. Other engineers claimed that the extensive use of water-cooled furnace walls would decrease furnace temperatures to such a degree as to interfere with complete combustion, and that this would result in increased losses and smoke. Other engineers claimed that the cheapest way of obtaining increased boiler capacity was by the installation of water-cooled furnace walls, which, by reason of seeing the fire, absorb heat at extremely high rates as compared to those portions of the boiler which do not see the fire. An evaluation of very extensive operating experience during the last four years has shown that water-cooled furnace walls do effectively accomplish the following aims which are listed in the order of their importance:

1. By either the entire elimination of refractories or the effective cooling of them by closely adjacent boiler tubes, it has been possible to eliminate refractory troubles and to increase very materially the rates at which fuel can be burned.
2. By materially increasing the amount of water-cooled surface which sees the fire, it has been possible to decrease appreciably the maximum rates of heat transfer and correspondingly to decrease the danger of burning tubes incident to the collection of a very small amount of scale. The possibility of failure of tubes incident to the temperature stresses resulting from high rates of heat transfer has also been minimized. This latter effect is particularly important in connection with the use of thick wall tubes which are necessary for higher pressures. Indicative of the trend toward lower average unit rates of heat transfer for the surface which sees the fire, in many boilers installed ten or fifteen years ago and fired by means of short underfeed stokers, rates of heat

transfer in the bottom half of the lower row of tubes were found by several investigators to be in the neighborhood of 100,000 B.t.u. per sq. ft. of surface per hr., corresponding to maximum load at 250 per cent (8.4 k-B.t.u. per sq. ft. per hr.) rating. In contrast there are boiler units being installed and in operation today for use at maximum evaporation which would correspond to 1200 per cent (40 k-B.t.u. per sq. ft. per hr.) rating. Boiler rating is based on the area of the boiler alone, but as the furnace walls are water-cooled, the maximum rate of heat transfer for the bottom row of boiler tubes, or for any portion of the water-cooled surface which sees the fire, has been rarely found to exceed 70,000 B.t.u. per sq. ft. per hr. Here again the trend of design of the steam generating unit parallels the design of electrical machinery and has for its purpose the limiting of hot spot metal temperatures in the pressure parts. This problem of limiting the maximum unit rates of heat transfer for the radiant heat absorbing surface requires skillful design not only of the boiler and the superheater but also of the furnace and the fuel burning equipment. The laning of the gases in the furnace, blow torch action impinging on the heat absorbing surface, lack of uniformity in the fuel beds, and penetration of the slag screen by the flame from vertically fired pulverized fuel burners, all result in high rates of heat absorption in localized areas, and result in high local hot spot temperatures.

3. Except for very low rates of evaporation, the effect of water-cooled furnace walls on unburned fuel losses, smoking and the overall efficiency of the boiler unit has been very slight.
4. The use of water-cooled furnace walls has very materially reduced the cost of boiler maintenance, and has increased the number of hours per year that each boiler unit is available for service.
5. The use of water-cooled furnace walls has apparently minimized the collection of slag on the tubes at the inlet to the first pass of the boiler.

The improvements in fuel burning equipment and the use of water-cooled furnace walls have, as indicated above, made it possible to carry very much higher rates of evaporation. Additional factors have entered in, however, to make it possible to increase the total amount of steam produced by a single boiler unit. Longer boiler tubes are being used both in connection with straight-tube cross-drum boilers and also for bent tube boilers. The total width of boilers is being increased incident to the ability of manufacturers to fabricate longer drums. Straight-tube cross-drum boilers for a width of 35 ft. between furnace walls are now available. Due to the increase in the length of tubes and also to an increase in number of rows deep for bent tube boilers and number of rows high for straight-tube cross-drum boilers, it is possible to increase materially the amount of heat absorbing surface per foot of furnace width.

The two trends, one toward the increase in the average rate of evaporation per square foot of boiler surface (this, by virtue of the water-cooled furnace walls, being accompanied by a decrease in the maximum unit rate of heat absorption for the surface which sees the fire) and the increase in the total amount of heat absorbing surface, have resulted in material increases in the maximum capacity of individual boiler units.

Nine years ago there were only a few boiler units in this country supplying steam under normal conditions of operation for a total generation of 10,000 kw., all of these boilers being installed in the stations of the Detroit Edison Co. Today there are at least twenty-four boiler units, either in operation or in the course of construction in this country, each unit to supply steam for a total of 35,000 to 40,000 kw., and three of these units will be capable each of supplying the steam required for 75,000 kw.

The combined effect of the work referred to above has been to decrease the investment per unit of installed boiler plant capacity.

The increase in the capacity of the individual boiler units has very much simplified the design of the boiler plant. In many cases the boilers are being arranged in a single row parallel to the turbine room, resulting in but one firing aisle and a maximum of light and accessibility to equipment.

The elimination of refractories, the decreasing of the maximum unit rates of heat transfer for the heat absorbing surfaces, the proper control of feed water treatment, and the improvement in details of design of the boiler unit proper, its fuel burning equipment and its accessories, are all tending toward an increase in the number of hours per year that the steam generating unit is available for service; this results in a reduction of the amount of spare boiler plant capacity. It seems probable, in light of our present knowledge, that for any station in which the use of a 60,000-kw. turbine is justified, it is equally possible to justify the use of a 60,000-kw. boiler, this by reason of the indication, yet to be verified in its entirety, that a large, well-designed steam generating unit at least equals in reliability and sustained availability for service a turbine-generator of equal capacity.

The development of high rates of evaporation from a single steam generating unit and the extensive use of water-cooled furnace walls has made a careful consideration of the problems of circulation for each steam generating unit of increasing importance. That the problems incident to the provision for proper circulation are not too difficult of solution is evidenced by the moderate amount of trouble experienced in the large number of installations made during the last four years. The problem of circulation is worthy, however, of careful study. Two worth-while reviews of this subject are included in a later section of this report.

One of the most difficult problems incident to the operation of large steam generating units at high rates of evaporation is the proper control of feed water delivered to the boiler. The statements from certain of the operating companies serve to define this problem, and statements from certain of the manufacturers outline the development work which they are doing. A trend is indicated toward the use of more water storage capacity in the boiler and a combination of water level and differential pressure control either in connection with the feed pumps or the individual boilers.

Increases in the maximum rate of evaporation and in the maximum steam production from a single unit make it correspondingly difficult to limit the amount of moisture carried over from the boiler to the superheater. Much development work done during the last two years on this problem is now bearing fruit. It appears that we may reasonably expect equipment which is now available to limit the moisture carryover from the boiler drum to the superheater to one-half of 1 per cent, corresponding to the maximum rate of evaporation.

The collection of slag at the inlet to the first pass of the boiler, particularly when burning low-grade coal, has served in a great many instances to limit the capacity of the steam generating unit. Complete correction of these difficulties involves a study of combustion conditions, as well as the development of proper slag screens to reduce the extent of slag collection. Unless the combustion of the fuel is completed in the furnace, one cannot obtain the full benefit of slag screens designed to decrease the amount of slag collection on the tubes.

It is practically impossible for most installations to develop the proper economic value from a steam generating unit without the use of induced draft fans.

The use of considerable amounts of power for driving the induced draft fans must accompany the development of high rates of evaporation. It is not unreasonable in connection with a steam generating unit evaporating 500,000 lb. per hr. to use as much as 1000 h.p. for the drive of the induced draft fans. It seems entirely reasonable in connection with the very large steam generating units which are being installed today, to install two induced draft fans in order that trouble in connection with one of these fans will result in a decrease of not more than 30 per cent in the steaming capacity of the unit.

As indicated earlier, one of the combinations offering a possibility of excellent station economy with moderate investment is that involving the use of a pressure of the order of 600 lb. and a temperature of the order of 800 deg. fahr. with no reheat.

Cost of Maintenance

The most important factor in reducing the cost of maintenance in the boiler house has been the elimination of refractories incident to the use of water-cooled furnace walls. Improved methods of feed water treatment have also been effective.

There seems to be a trend away from the use of steam soot blowers in connection with underfeed stoker-fired boiler units. A factor in connection with this trend has been the high cost of maintaining the blowers. In a number of cases appreciable losses of boiler tubes resulted from impingement of steam from blower nozzles. In contrast, however, the trend seems to be toward a continued use of steam soot blowers for pulverized fuel fired boilers and their superheaters; for the cleaning of economizers in connection with both stoker-fired and pulverized-fuel-fired boilers; and for the cleaning of superheaters in connection with stoker-fired boilers.

For certain installations burning low-grade coal, soot blowers have proved ineffective for the cleaning of economizers and water washing is being resorted to. Water washing has also proved quite effective in a number of cases for the removal of scale from the external surfaces of boiler tubes, the water washing being done while the boiler is out of service.

It would appear that in the interest of reduced maintenance cost and improved reliability, more careful routine inspection of the boiler and superheater tubes and the use of methods that will eliminate faulty tubes are justified. At least some work along this line is now in progress.

There is a rather general adoption of the use of protective coatings for the internal surfaces of boiler drums, boiler and economizer tubes. There is also a rather widespread adoption of the practice of removing mill scale from the internal surfaces of tubes and drums of new equipment in order to permit the application of protective coatings before initial commercial operation.

Aside from obtaining an adequate solution of the problem of steam distribution in the superheaters, it appears that we must, from the standpoint of safety of operation and reduction of maintenance, insist on the simplification of headers and the elimination of baffles and ferrules in new designs.

Reduction in Operating Labor

The reduction in the number of boiler units, the simplification of boiler plant design, and the use of combustion control equipment have all been effective in reducing the cost of operating labor in the boiler house.

In practically each case the statements which follow constitute detailed descriptions of the different phases of steam generating unit design, the general trends of which have been outlined above. The subcommittee has asked the manufacturers to prepare their statements so as to indicate the way in which they have been relating their development work to the accomplishment of the reasonable objectives which were outlined earlier in this statement. We believe the manufacturers have complied admirably.

Probably the most worth-while piece of work which has been undertaken in recent years relative to the development of boiler plant design and operation is the study being conducted by C. F. Hirshfeld of the Detroit Edison Company covering the extent and cause of outages in connection with steam generating units. Operating records of most of the representative stations of the country are being compiled covering the period of operation from Aug. 1, 1928. to Aug. 1, 1929. The analysis of these operating records by the engineers who compile them and the analysis and comparison which will be made by Mr.

Hirshfeld should do much to focus the attention of operating engineers on improved methods of operation and maintenance which will decrease the percentage of outage hours, and to center the attention of the designing engineers on the improvement of details which will result in a reduction in outage hours. The overall results of this analysis, which are to be presented in a paper before the annual meeting of the American Society of Mechanical Engineers in December, 1929, are awaited with interest.

The important problems of reducing the investment per unit of installed capacity in the boiler house and of maintaining each piece of steam generating equipment available for service the maximum possible number of hours per year deserve the best thought of operating and designing engineers.

SURVEY OF OPERATING STEAM TEMPERATURES

The use of increasingly high superheated steam temperatures in central station practice has made it desirable to make a survey of operating practice. Definite information has been received relative to the temperatures obtaining in 81 representative stations. The results of the survey are shown in Fig. 2 and Table I on the next page.

MISCELLANEOUS STATEMENTS

Circulation in Water-Cooled Furnace Wall Circuits

STATEMENT BY GEORGE A. ORROK AND N. ARTSAY, 52 VANDERBILT AVE., NEW YORK, N. Y.

In the earlier years of boiler construction and operation when fire tube and shell boilers were standard, it was appropriate to consider the bubbles of steam apart from hot and cold water and their effect on the circulatory system. Later when water tube boilers and steam pressures up to 300 lb. were the rule, ideas on circulation became highly individual and many boiler models were evolved, most of which, through troubles, were soon eliminated. Quite naturally, designers still thought in terms of bubbles, and the idea of the "free path for the bubbles of steam" may be still seen here and there in boiler literature and designs.

With the present high pressures, high rates of heat absorption, and the extension of radiant heat surface, it is time to consider the close mixture of water and suspended steam bubbles which in its action resembles an emulsion or perhaps a colloid. In modern steam generators, satisfactory circulation in the "boiler" part is taken for granted, since for some time most of the unsatisfactory types have been eliminated. The connection between the "furnace walls" and the main circulation and the effect of this connection on the whole circulatory system is still a matter of conjecture, with the usual natural consequences. As to circulation in the water wall circuits proper, very little has been published, although many plants have run tests to ascertain the state of water or its mixture with steam behind the surfaces exposed to the radiant heat. The variety of engineering opinion as to what happens in these furnace

wall tubes makes a theoretical investigation in a first approximation desirable, and the present article will deal with a simple furnace wall circuit beginning and ending in the boiler drum. Fig. 3 shows the circuit. Let us denote:

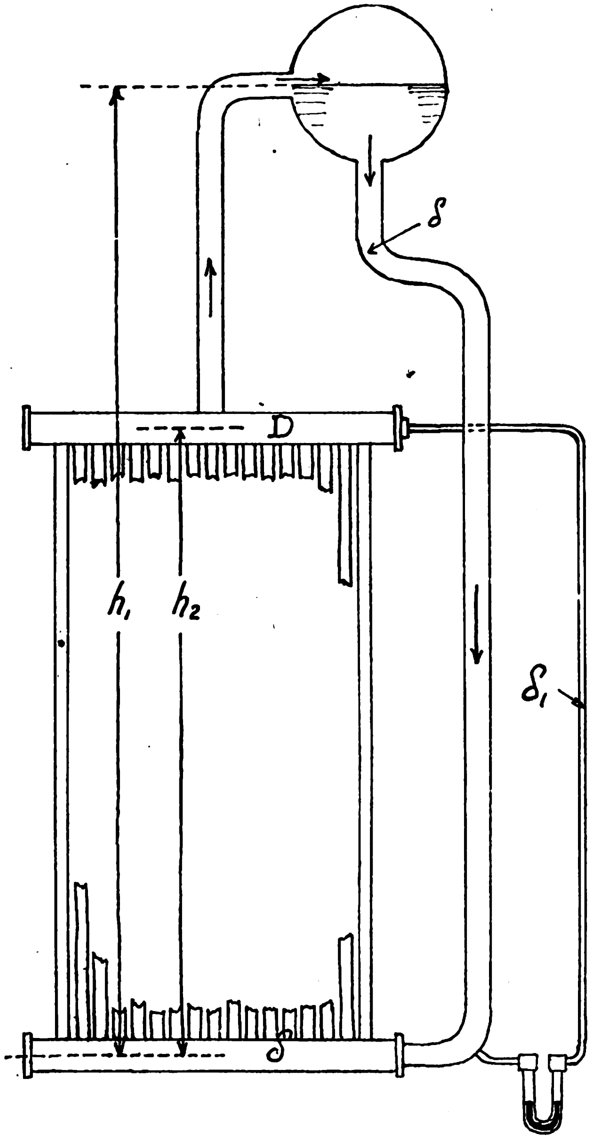

FIG. 3—Typical Water-Cooled Furnace Wall Circuit Considered in Calculating Circulation. Orrok and Artsay.

H = Total heat absorption in the circuit, B.t.u. per second.
p = Circulation of water, pounds per second.
λ = Latent heat of evaporation, B.t.u. per pound.
h_1, h_2 = Heads in feet as shown in Fig. 3.
δ = Density of water at saturation temperature.
Δ = Density of dry steam at drum pressure.
D = Density of the mixture entering the drum. All densities in pounds per cubic foot.
S = Orifice of the circuit into the drum, square feet.
αp^2 = Hydraulic resistances in feet solid water column in different portions of the circuit.

In the first approximation to the actual conditions, that is, neglecting the variation of boiling point along the vertical direction of the circuit, we can write:

$$D=\frac{\delta}{1+\frac{H}{\lambda p}\left(\frac{\delta}{\Delta}-1\right)} \qquad \text{(1)}$$

$$\text{or from (1)} \quad H=\frac{\lambda p\left(\frac{\delta}{D}-1\right)}{\left(\frac{\delta}{\Delta}-1\right)} \qquad \text{(2)}$$

By taking the outlet end of the circuit:

$$h_1\delta-h_2\times\frac{\delta+D}{2}-(h_1\text{-}h_2)D=\delta\left(\Sigma\alpha+\Sigma\alpha\frac{\delta}{D}\right)p^2+\frac{D}{2g}\left(\frac{p}{DS}\right)^2$$

which reduces to:

$$\left(h_1-\frac{h_2}{2}\right)(\delta-D)=\delta\left(\Sigma\alpha+\Sigma\alpha\frac{\delta}{D}+\frac{1}{2g\delta DS^2}\right)p^2 \qquad \text{(3)}$$

The most convenient way of using the equations is to choose a set of values for D and calculate p's from (3), plotting them against H calculated from (2). The resistance factors $\Sigma\alpha$ for the stretches where water moves in a solid column change to $\Sigma\alpha\,\frac{\delta}{D}$ and where the density of hot water is decreased by the presence of steam bubbles. The increase in the factor for the mixture of steam and water is due to the higher velocity of the less dense fluid and the second power of the velocity element. The resistance factors refer to the flow in pounds per second and can be derived from any suitable formula of hydraulic resistance corrected for the temperature of the water. Let us take now a numerical example. Let the circuit contain 300 sq. ft. of projected heating surface 20 ft. high (h_2), the bottom header of which is 30 ft. (h_1) below the level of water in the drum. The inlet and outlet pipes are 8-in. diameter inside, and the resistance of the circuit is equivalent to an 8-in. pipe, 240 ft. long, of which length 140 ft. will be in the region of solid water, while 100 ft. are in the region of the steam water mixture. The evaluation of resistance gives $\alpha=\frac{89}{\delta}\times10^{-6}$ ft. per foot circuit length of the 8-in. pipe per lb. per second of circulation; δ is the pounds of hot water per cubic foot.

Calculations were made for 150, 300, 600 and 1500-lb. steam pressures, and the results are represented in Fig. 4 and 5 plotted against heat absorption in B.t.u. per hr. per sq. ft. of projected water wall surface. First we notice that the circulation is quite intense already at moderate rates of heat absorption. With the increase of bubble content, the resistance in the mixture part of the circuit begins to be felt and reduces the amount of water circulating per second. This is clearly seen on Fig. 4 from the curves of inlet solid water

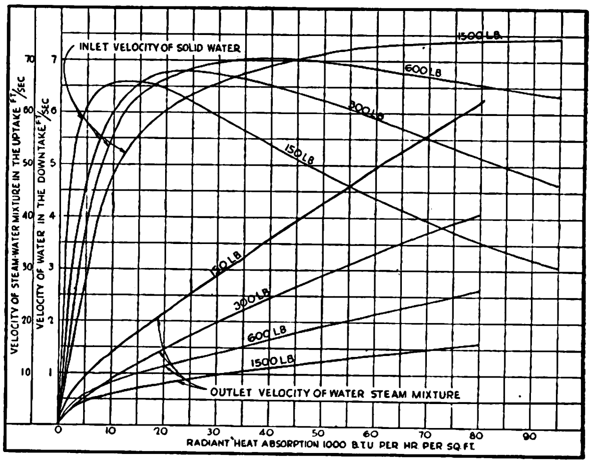

FIG. 4—Water-Cooled Furnace Wall Inlet and Outlet Velocities. Orrok and Artsay.

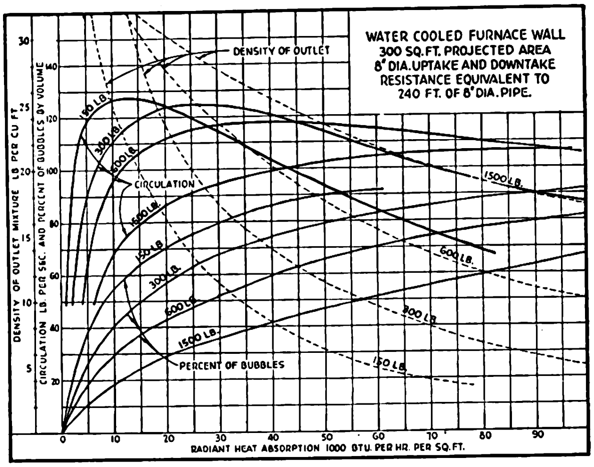

FIG. 5—CIRCULATION CHARACTERISTICS, WATER-COOLED FURNACE WALLS. ORROK AND ARTSAY.

velocity. Next we notice the beneficial effect of higher pressure on the mean density of the fluid in the circuit. This fact is reflected in the steadier water level at variable steam demand observed in the high-pressure boilers. The percentage of bubbles shown on the curves of Fig. 5 gives the indication of the actual state of the steam-water mixture in the tubes. At high ratings, one might say, the tubes are blowing out very wet steam, and in this they approach the flash type of evaporating coils.

Suppose now that we connect a closed mercury U-tube with the upper and lower headers as shown on Fig. 3, the connecting tubes being filled with solid columns of water. The indications of such a device need an interpretation even in the first approximation. If we denote by δ the lb. per cu. ft. of cold water in the small connecting tubes of the device, by v the velocity in the lower header, and by m the reading of the mercury U-tube in inches, then

$$m = \frac{12}{13.6}\left[h_1\left(1-\frac{D}{\delta}\right)-h_2\left(\frac{\delta 1}{\delta}-\frac{D}{\delta}\right)+\frac{v^2}{2g}\left(\frac{\delta}{D}-1\right)-\alpha_2\frac{\delta}{D}p^2\right]\frac{\delta}{62} \quad . \; . \; . \; . \; . \; (4)$$

where α_2 is factor of resistance in the uptake.

It is quite tempting to neglect the resistance and the velocity heads and to consider the U-tube readings as reflecting the densities only. In such a case:

$$m = \frac{12}{13.6}\left[h_1\left(1-\frac{D}{\delta}\right)-h_2\left(\frac{\delta 1}{\delta}-\frac{D}{\delta}\right)\right]\frac{\delta}{62} \quad . \; . \; . \; . \; . \; (5)$$

but the value of the neglected terms is so large that the positive reading m, according to (5), must be negative, according to (4), due to the cold column of water in the connecting tube, as can be easily ascertained by using data in Fig. 4 and 5. This effect of velocity and resistance must be always kept in mind in setting up a test device.

Several secondary phenomenæ occur in circuits such as the one here described.

1. The inlet velocity into the circuit at average ratings is of the order of 6.5 ft. per second, involving a pressure drop of about ¼ lb. per sq. in. or boiling point drop of about 0.1 deg. fahr. However small is this drop of temperature, it involves a partial evaporation which will reduce the density in the top of the downtake by about 6 per cent, which will be equivalent to a restriction of the passage and hence should be considered as an additional resistance. This effect is greater at lower steam pressures.
2. The height of water column above the center of the heating surface is considerable, 20 ft. for this case and more in many instances. The involved rise of the boiling point varies from 3.8 deg. fahr. (150 lb. pressure) to 0.5 deg. fahr. (1500 lb. pressure), and the superheating of water is equivalent to a retardation in the evaporation. It is possible to estimate the order of this effect. The average circulation is 120 to 100 lb. per second (150 to 1500 lb. pressure). Hence the percentage of latent heat involved in superheating of water is 0.52 per cent to 0.09 per cent. At 45,000 B.t.u. per hr. per sq. ft. heat absorption rate (= 3750 Bt.u. per second in the circuit), the percentage of the circulating heat capacity involved in the absorption is 3.9 to 6.75 per cent and the shift upward of the center of evaporation will be 2.67 ft. and 0.27 ft. at 150 and 1500 lb. per sq. in. pressures. The effective heads h_1, h_2 of the circuit must be correspondingly reduced, but the correction is slight.

The elementary calculations shown here permit us to estimate the effect of connecting a furnace wall circuit to the boiler circulation. Many surprising effects can be anticipated, but in this connection every case will be an individual one, where the dimensions and pipe connections play the most important role, and it is impossible to deal with these cases in an article of general character.

Steam Generating Capacity of the Water Tube Boiler

STATEMENT BY E. B. POWELL, CONSULTING ENGINEER, STONE & WEBSTER ENGINEERING CORP., BOSTON, MASS.

In the past it has been customary to regard the potential capacity of the modern water tube boiler as limited only by the increase in moisture carry-over with the steam. It was felt that, while undoubtedly there was a theoretical limit to the rate of circulation which could be attained, given clean heating surfaces, the circulation would be adequate to meet safely the maximum commercial requirement. Meanwhile, however, the introduction of the boiler separator has removed the problem of moisture carry-over as a factor in steam boiler capacity, and within the past few years the greatly increased rates of steam generation have in a number of instances been found to overtax the circulation capacity of the individual boiler. Similar experiences have been encountered with many types of furnace water walls.

The boiler circulation is, of course, merely a problem of heat absorption on the one hand and of hydraulics on the other. We now have very dependable heat transmission formulas, and one might expect that suitable hydraulic formulas would be equally available. Unfortunately, however, there are very large gaps in our data on both aspects of the problem. The work of Broido, Orrok, Wohlenberg, Haslam and Hottel, supplemented by the field investigations of Kreisinger and of Sherman, have accomplished much toward clearing our understanding of the factors influencing the temperatures in different parts of the boiler furnace, but we are still unable to predict with assurance, for untried conditions, the temperatures which will obtain in the path of the combustion gases at any short distance beyond the boundaries of the furnace. Dependable values for such temperatures are, of course, essential as a basis for the application of our heat transmission formulas. Consideration of the hydraulic aspect of the problem has suggested some very creditable theories, but there are extremely few data of definite value on the properties of mixed fluids such as obtain in the boiler circulating system.

It is true that, with our present information, limitations of boiler circulation can be estimated as rough approximations. However, the question of maximum dependable boiler capacity is of such increasing importance that further research appears highly desirable. The problem is suggested for the attention of our recently formed Special Research Committee. In the meanwhile it would seem advisable, because of the absence of data required for definite determinations that estimates of steam boiler capacities and of water wall circulation requirements include a conservative factor of safety.

Thermal Stresses

STATEMENT BY GEORGE A. ORROK AND N. ARTSAY,
52 VANDERBILT AVE., NEW YORK, N. Y.

The minuteness of the effects of thermal expansion in metals and the same order of magnitude for the elastic deformations, in the majority of cases being invisible to the naked eye, has without doubt been the cause of the widespread neglect of these most important stresses produced by inequalities of temperature even in continuous pieces of metal.

The condition of very long metallic members in a structure (pipes, rails), or very small clearances (steam turbines), very limited total deformation before breakdown (cast iron, glass) and very large temperature differences (welding, shrinkage stresses at cooling of castings), represent the phenomena of thermal stresses with obvious visible results. Practically every piece of metal anywhere is subject to these stresses; for instance, the millions of frying pans in daily use. In the great majority of cases these stresses pass unnoticed because they do not inflict any permanent harm. This high percentage of harmless effects has detracted from the attention due to the small residual where danger occurs.

Thermal stresses are usually superimposed on mechanical stresses, and hence the case of thermal engines deserves a closer attention from this viewpoint than is given at the present moment, and power station engineers must be on the continuous lookout for trouble which may be caused by them.

Let us take open-hearth steel with a 40,000 lb. per sq. in. elastic limit, 30×10^6 lb. per sq. in. Young's modulus and a 6.3×10^{-6} coefficient of thermal expansion per deg. fahr. These figures mean that a temperature difference of 215 deg. fahr. across a closed contour or in a system with restricted expansion will produce stresses equal to the elastic limit. If the steel is under stress already, then lesser inequalities of temperature may produce residual deformations. If the thermal conditions are fluctuating around some such values, fatigue will set in with the course of time. If the metal is already strained in the same main directions as the running thermal stresses, the fatigue limit will be reached with smaller temperature differences.

For instance, very often the feed water is 100 to 150 deg. fahr. below the temperature of saturated steam in boiler drums; the streamlets of the colder feed which have not yet mixed thoroughly with the hotter boiler water may reach the drum walls and thus cause the fatigue in spots where the sum of thermal and mechanical stresses is above the fatigue limit. Such spots may be numerous in a boiler drum, the most common ones are under the rivet heads and in the curved drum heads. The continuous agitation of water in the drum will produce the necessary number of stress changes and minute fatigue cracks will appear which will be further worn out by the chemical action of the boiler water and its impurities. This may be the explanation of the so-called caustic embrittlement of boiler plate.

Let us take a boiler tube 0.4 in. thick, exposed to radiant heat and let, additionally, a flame play on it. The total heat transfer in such conditions may easily reach 150,000 B.t.u. per hr. per sq. ft. The heat conductance of open-hearth steel is approximately 300 B.t.u. per hr. per sq. ft. per deg. fahr. per in. thickness. Thus in the tube 0.4 in. thick transmitting 150,000 B.t.u. per hr. per sq. ft. there will be a temperature difference of 200 deg fahr. between the outer and inner surfaces. A complete analysis of such a case (see paper on "High-Pressure Boilers," A. S. M. E. Trans., 1928) will show that the outer fibers of the tube will be not only relieved of tension due to pressure but also compressed to a serious extent. The inner fibers, consequently, have to bear a very much increased stress of tension. The "creep limit" will be passed and the metal will begin to thin out locally, with a blister as the result. Many other points of large thermal stresses may be found in any boiler.

Let us take now a turbine blade. In the wet zones of steam expansion a droplet of moisture separated from the steam may strike the blade with a high velocity. A shock at 700 ft. per sec. relative velocity will heat up the droplet instantly, raising its temperature and of the nearest thin layer of the metal about 10 deg. fahr. In the wet zones of steam expansion the turbine blading has the temperature of the under-cooled steam. Stodola's investigations,[1] permit us to consider the 3.5 ratio of under-cooling, meaning that the actual temperature of steam below the saturation line on the Mollier chart corresponds to a pressure equal to

$$\frac{1}{3.5} = 0.286$$

of the actual value. We may thus expect in the lower pressure stages of a turbine an under-cooling of 50 to 60 deg. fahr. Whenever a droplet of moisture strikes the metal it is flattened immediately, with consequent breaking of the unstable state of under-cooling. Thus, the mean temperature of the spot hit by a droplet will be about 65 deg. fahr. higher than the temperature of the surrounding metal. The thermal stress involved locally on a polished blade surface will be about 14,000 lb. per sq. in. for nickel steel and 19,000 lb. per sq. in. for brass. To this must be added the very indefinite stress due to the kinetic energy of the shock. The metal of the blade is well stressed already by centrifugal force, vibration and steam impulse, hence the addition of recurrent thermal stresses of this value will produce fatigue and the microscopic cracks so often reported. Once the latter set in, the shearing stresses parallel to the surface, evolved by the thermal conditions, will begin to act and will scale off minute portions of metal. We may go even deeper: in the crystalline structure of the blade alloy the steep temperature gradients (due to the smallness of droplets and space affected) and the uneven heat conductance and thermal expansion between the crystals may produce a loosening of the structure and hence more marked and serious erosion.

A blade already slightly corroded, will present a very uneven surface layer and to the surface stresses of compression and tension must be added stresses due to bending moments; it is obvious that the rate of erosion will increase quickly. The actual behavior of blade metals in service strongly supports this idea. Moreover, a study of steam conditions across a blade shows that the maximum erosion occurs in places in the curved steam path where the pressure of steam falls off and under-cooling and temperature differences are greater.

One well-organized turbine and boiler concern in Europe has promulgated a rule in its design departments to write all the stress calculations in hot metals in red pencil while calculations for cold metals are written in black. This is being done to call continuous attention to the change of resistance in materials at high temperatures as well as to the possibility of thermal stresses.

With proper attention paid to the thermal stresses on the part of operating engineers who have the opportunity to observe the different manifestations of these forces and on the part of designing engineers who have the means of analysis, some common troubles with metals may be well reduced if not avoided entirely by judicious criticism of present constructions.

It is most desirable to collect in one place information on all the troubles in power plants which may be attributed to thermal stresses and to arrange a periodic survey of the general conditions producing these troubles. The Prime Movers Committee of the N. E. L. A. seems to be the proper place for this work.

Embrittlement in Steam Boilers

STATEMENT BY FREDERICK G. STRAUB, ENGINEERING EXPERIMENT STATION, UNIVERSITY OF ILLINOIS, URBANA, ILL.

[This article is an elaboration of part of the material that has appeared in Bulletins 155 and 177 of the Engineering Experiment Station of the University of Illinois. The publication of this article has been authorized by Dean Ketchum, Director of the Engineering Experiment Station.]

The subject of embrittlement of steam boilers has received much consideration in the reports dealing with feed water treatment. Operating engineers frequently find it necessary to consider whether or not their boilers, or proposed boilers, will be subject to this distress. They call in their chemical staff and ask for data, and the chemist turns to the reports and finds that he must work to a so-called sulphate to alkalinity ratio. This, in turn, is dependent on the boiler pressure. To determine this ratio he refers to the A. S. M. E. Boiler Code, which recommends ratios up to 250 lb. per sq. in. pressure. If the boilers under consideration operate above 250 lb., he is at a loss to know what to recommend. If he finally decides upon a desired ratio, he must then determine how much effort must be spent in maintaining this ratio. Shall it be a lower limit, an average or a value to be reached once in a while? Furthermore, what alkalinities must be considered in maintaining these ratios?

---

[1] A. Stodola, Dampf und Gas Turbinen, 6th edition, par. 41, page 96; par. 178, page 853.

Much effort has been expended in attempting to clear up the uncertainties connected with the subject of embrittlement. To date there is much unknown about this cracking of boiler plate which occurs very rapidly and with practically no warning. On the other hand, much definite knowledge is available, and a brief résumé of this is as follows:

1. The cracking is the result of using a water having too much sodium carbonate in respect to the sodium sulphate content.
2. The workmanship in the boiler is not necessarily the primary cause.
3. The quality of steel does not influence the cracking to any marked extent.
4. The cracks will occur at almost any period after about one year's operation.

If a water has sufficient sulphate, no cracking occurs. The A. S. M. E. Boiler Code has given ratios of sulphate to alkalinity for pressures up to 250 lb. This will undoubtedly be modified shortly to include pressures up to 600 lb. For increase in pressure the sulphate ratio should be raised. Thus, at 400 lb., 5 seems to be advisable, and at 600 lb. it should be about 7. These ratios are of sodium sulphate to total alkalinity expressed as sodium carbonate in the actual boiler water. They are not determined by the composition of the feed water.

Plant experience in the past has indicated that these ratios are minimum values that must be maintained at all times. One-half the ratio is no better than none.

Some engineers ask whether the undecomposed sodium carbonate in the boiler water could be considered as an inhibitant and be added to the sulphate. This is undesirable since the ratios are based upon actual plant data, which in turn allow for the various rates of decomposition at various pressures. The total alkalinity in the boiler water should be calculated as sodium carbonate, and this value compared to the sodium sulphate content in order to obtain the desired ratio.

If the boilers have been operating at intervals below the recommended ratios, it would be well to start a thoroughly systematic inspection of all seams in order to ascertain whether or not cracking has started.

Structural Stability of the Steam Boiler

STATEMENT BY E. B. POWELL, CONSULTING ENGINEER, STONE & WEBSTER ENGINEERING CORP., BOSTON, MASS.

In the last half dozen years, and particularly since the first 1200-lb. boiler unit was placed in operation at the Edgar Station in 1925, there has been frequent questioning as to the hazard involved in the operation of the new higher pressure equipment as compared with that for the lower pressures regarded as standard a short time before. A report rendered after the investigation of one of the instances of caustic embrittlement which came to attention in 1928 describes the failure of a cross-drum boiler in which the drum shell pulled apart perhaps ½ in. and, although the boiler was under full operating pressure of 400 lb., the escape of water and steam merely put out the fire and, beyond the boiler itself, caused practically no damage. The account of this experience, reinforced by the experience of tube failures under much higher pressures at the Edgar Station and at the Lakeside Station, Milwaukee, suggested that the pressure zone of maximum hazard from a steam boiler of present-day construction might lie below 425 lb. It appeared that the greater thickness of metal employed with the high pressures might give such stiffness that, notwithstanding the same factors of safety were applied for all pressures, there would be greater stability of shape under rupture in the higher pressure boiler.

A study of stresses in plates of thickness corresponding approximately to those used in the standard 54-in. cross-drum developed the following relations:

Length of plate element which, considered as a cantilever beam, will withstand drum pressure without exceeding elastic limit stress (27,500 lb. per sq. in. for the plates of the 150 and 450-lb. drums, and 37,500 lb. per sq. in. for the 1400-lb. drum forging):

Drum Pressure, Lb. per Sq. In.	Plate Thickness, In.	Element Length, In.	Length Ratio
150	0.60	4.7	1.0 (Base)
450	1.65	7.4	1.6
1,400	4.00	12.0	2.6

Relative deflection obtained under drum pressure in plate element considered as a cantilever beam of fixed length, so selected that stress will not exceed elastic limit:

Drum Pressure, Lb. per Sq. In.	Plate Thickness, In.	Deflection Inverse Ratio
150	0.60	1 (Base)
450	1.65	7
1,400	4.00	32

The deflection ratios shown in the second table would seem to afford the closer measure for the relative stability of the different drums. While these values cannot, of course, be regarded as demonstrating immunity from destructive explosion, even for the 48-in. drum of the 1400-lb. boiler, they do point toward a decrease in operating hazard for the higher pressures where suitable materials and modern construction are employed.

Operation of High-Pressure Cross Cracking Stills

Relative to the maximum availability of large boiler units which is reasonable of attainment, the Committee has considered it worth while to obtain from one of the large oil refining companies a statement for the calendar year of 1928 for operation of their sixteen high-pressure Cross cracking stills. The operating problems for the oil heaters are not unlike those encountered in the operation of high-pressure boilers and are in many respects more difficult.

Oil at a temperature of approximately 150 deg. fahr. is delivered to the suction of the reciprocating steam-driven feed pumps. The feed pumps deliver the oil to the inlet of the oil heater at a pressure of 800 lb. The oil heaters which are fired with still gas are arranged for series flow of oil, and there is no provision for storage of oil in the heater or for recirculation. Straight tubes are used in the oil heaters, and in general the construction is similar to that used in a high-pressure water economizer. The oil is heated to a temperature of 890 deg. fahr. The pressure drop through the heater averages 150 lb., but is appreciably higher than this near the end of the run, as a result of the heavy accumulation of coke in the tubes at the hot end. The oil is delivered at a temperature of 890 deg. fahr. and a pressure of 650 lb. into a forged steel drum, closely resembling the boiler drum for the 1400-lb. boilers in the Edgar Station in Boston, in which the liquid phase cracking takes place. The product is bled out of the reaction drum through a needle valve and delivered to a fractional distilling tower.

Each of the Cross cracking stills is made up of an oil heater with its feed pump, a reaction drum and a fractional distilling tower. The feed pumps of each pair of stills are interconnected so that one feed pump can supply oil to two heaters in parallel.

The flow through each of ten oil heaters is 52 g.p.m.; for each of three oil heaters, 117 g.p.m., and for the remaining three oil heaters, 140 g.p.m.

The operating records for each of the sixteen stills are shown in Table II. The sixteen stills were on stream (in effective operation) during 1928 an average of 92.63 per cent of the hours in the year. They were down cold for an average of 214 hr. for each still. The work performed during a periodic cleaning is: Cleaning coke out of tubes, cleaning coke out of reaction drum, taking down high-pressure piping for cleaning and inspection, and cleaning of fractional distilling towers. The tubes in the oil heaters are inspected for defects during each periodic cleaning and changed when necessary.

Table II

Outage Schedule, Oil Refinery

Number of Still	Time on Stream, Hr.	Times Down for Periodic Cleaning	Average Time Required for Periodic Cleaning, Hr.
1	8,213	32	18
2	8,147	31	20.5
3	8,177	33	18.5
4	8,182	32	18.75
5	8,142	34	19
6	8,204	32	18
7	8,016	33	23
8	8,249	32	16.5
9	8,275	31	16.5
10	8,266	31	16.5
11	8,101	30	22.5
12	8,089	29	24
13	7,840	31	30.5
14	8,135	23	28
15	7,913	27	32
16	8,221	29	19

This same company is installing four additional Cross cracking stills, each to have a capacity of 400 g.p.m. A single turbine-driven centrifugal feed pump will supply oil to each oil heater, with no cross connections. Oil will be delivered to the feed pump suction at a temperature of 650 deg. fahr. and to the inlet of the oil heater at a pressure of 1500 lb.

Statement by the American Uniform Boiler-Law Society, 253 Broadway, New York, N. Y.

During the past two years the activities of the Chairman and Administrative Council of the American Uniform Boiler-Law Society have been directed toward bringing into accord the Massachusetts Boiler Rules and the A. S. M. E. Boiler Code. It has been rather a long and tedious struggle covering some years, but practically all minor differences have been eliminated and only one or two major differences remain to be adjusted.

During the coming season of the convening state legislatures it is intended to take up the question of code legislation, if advisable, in Virginia, Illinois, Colorado, Florida, Georgia and possibly others, if upon investigation it is deemed advisable to introduce code legislation. Sometimes, under certain local conditions, it does more harm to advocate code legislation during a session than to wait until a later date when conditions have become more favorable. There are two or three of the states named in which the possibilities of code legislation being enacted are good, such as Colorado and Florida. The Florida Engineering Society has gone on record unanimously in favor of A. S. M. E. Code legislation, and has appointed a legislative committee to work with this Society.

A number of bills were introduced during the above period in several code states that were inimical to the best interests of this society as well as its members, and it was necessary to use a great deal of time and effort in order to insure the non-passage of these bills. In one instance it was necessary to appeal to the governor of the state.

The Society has been, and is at the present time, spending as much time, labor and expense in keeping the present code states in line, in order not to disrupt the uniform practice of administering the code, as in introducing new code legislation. At times it has been found difficult to convince some of the administrative powers that a change in their law to meet local conditions, if followed by other code states would entirely disrupt the uniformity which took much effort to bring into being and to maintain.

A part of the work that may not be generally known consists of acting as advisors to the several boiler inspection departments on matters pertaining to the Boiler Code, inspection rules and administration. From time to time it has been possible to adjust differences that have arisen between Society members and the inspection departments. A few of our contributors, not knowing these conditions, have been under the impression that since eighteen states have adopted the Code, others would be added to the list without any work on the part of the Society. This is far from being the case. The work of the Society includes:

Keeping in constant touch with the administrative authorities and legislatures in the eighteen states which have adopted the Code,

Acting as a clearing house for matters vital to the administration of the A. S. M. E. Uniform Boiler Code,

Watching bills that are inimical to the Society's interests.

STATEMENTS BY OPERATING COMPANIES

Statement by the Alabama Power Company, Birmingham, Ala.

New Boilers at Gorgas Steam Plant

Two new boilers of 30,315 sq. ft. each for supplying steam to a 60,000-kw. unit known as Gorgas No. 4, will be ready for operation in April, 1929. These boilers are designed for 475 lb. drum pressure with superheater outlet conditions of 462 lb. and 725 deg. fahr. at 350,000 lb. per hr. normal output. The maximum rating on each boiler is 450,000 lb. per hr., at which the corresponding pressure and temperature are 453 lb. and 740 deg. fahr. The drums are 72 in. dia., 34 ft. 2¾ in. long, and are said to be the largest size built for 475 lb. pressure. Interdeck superheaters are located above the first deck of 7 boiler tubes.

Three sides of the furnace are water-cooled with fin tube water walls having a total surface of 3505 sq. ft.—900 sq. ft. in each side wall, 1180 in the rear wall and 525 in the hearth screen. The furnace volume is 24,000 cu. ft., which at normal ratings will give a heat liberation in the furnace of 18,000 B.t.u. per cu. ft. per hr.

Each boiler is equipped with a C. E. Corp. plate type air preheater with a total heating surface of 30,600 sq. ft. The preheated air will range in temperature as follows:

Rating, lb. per hr.	Air Temp. Leaving Heater, deg. fahr.
160,000	372
300,000	422
350,000	445
450,000	492

Fig. 6 shows the calculated performances expected from this unit at various ratings.

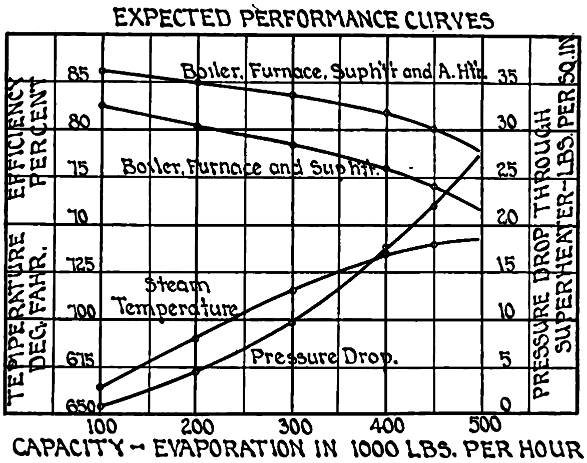

FIG. 6—Calculated Performance Data, Gorgas Steam Plant. Alabama Power Co.

Statement by W. S. Barstow & Company, Inc., Reading, Pa.

Boiler Units in the Holland Station

In considering the steam generating units for the Holland Station, it appeared that the building of each steam generator with its reheater as one unit would facilitate operation, simplify regulation and would cripple the plant less if one steam generator went out of service.

The first arrangement considered consisted of a bent tube boiler with an interdeck convection superheater, combined with one of the radiant type, and a reheater consisting of radiant type apparatus located in the side walls of the setting. This proposed arrangement of equipment was not entirely satisfactory.

After carefully considering all of the possible arrangements of water walls, boiler, superheater, reheater, economizer and air preheater, taking into consideration the cost of the various equipment, it appeared that the best arrangement was a first stage steam reheater and a second stage gas reheater with a convection type superheater, an economizer and an air preheater. The distribution of surfaces is as follows:

	Sq. Ft.
Boiler	7,928
Water walls and screens[1]	2,194
Superheater, approximately	4,600
Steam reheater	1,508
Gas reheater	11,450
Economizer	11,880
Air preheater	32,450

[1] No. 1 boiler with fin tubes on rear and front walls —2194 sq. ft.

No. 2 boiler with plain tubes on rear and front walls —1866 sq. ft.

Steam from the boiler flows to the convection superheater and thence to the high-pressure section of the turbine, which exhausts to the steam reheater operated in series with a flue gas reheater. It is then returned to the low-pressure section of the turbine. Saturated steam from the boiler is used for heat supply in the steam reheater, constant reheat temperature being obtained by thermostatic regulation of the steam. The proportions of the two reheaters are so arranged that at full loads the steam reheater is nearly cut out, the flue gas reheater furnishing all the heat required.

Comparisons between bent tube and straight tube boilers favored the adoption of the straight tube type for this case, there being four major considerations: (1) in high-pressure boilers, drums constitute the greatest expense, and the straight tube boiler with one drum had an advantage in cost; (2) the straight tube boiler allowed a more satisfactory arrangement for the gas reheater, it being difficult to place this between the first and second passes of the bent tube boiler; (3) the straight tube boiler allows all of the high

priced boiler surface to be located in the highest temperature zone with the reheater immediately above, and makes the most economical general arrangement of all the heating surface; (4) the straight tube boiler construction lent itself more economically to space considerations with the desired method of pulverized fuel firing.

Each boiler is to be built for a maximum capacity of 250,000 lb. of steam per hr. at a pressure of 1400 lb. per sq. in. The boiler section will consist of one forged-steel steam and water drum, 52 in. inside diameter by 4 in. thick, 46 ft. 0 in. long, connected by circulating tubes to 45 sections, each section consisting of 8 tubes, 3¼ in. o. d., 20 ft. 0 in. long, expanded at each end into headers sufficiently long to accommodate 13 tubes. The tubes are so arranged in each section that, counting from the bottom, the second, fourth and sixth spaces on the headers are to be left blank to form a slag screen, and the twelfth and thirteenth spaces are to be left blank, so that additional tubes may be added later.

The connections from the sections to the steam drum will be provided by a row of horizontal circulating tubes, curved at one end to enter the top of the corresponding uptake header. These tubes will enter the steam drum in two horizontal rows. The downtake end of the sections will be connected to the steam drum by one row of circulating tubes. Each section will be connected at the bottom to a wrought steel mud drum by nipples.

STATEMENT BY THE BROOKLYN EDISON COMPANY, INC., BROOKLYN, N. Y.

Operation of No. 5 Unit, Hudson Ave. Station

A statement covering a description of the No. 5 unit installation at Hudson Avenue Station was given in the 1928 Report of the Boilers, Superheaters and Economizers Subcommittee (N. E. L. A. Publication No. 278-65). These boilers have been in operation since September, 1928, and have given very good performance from the start. The superheat was slightly high at first, and in order to limit the maximum steam temperature from 730 to 740 deg. fahr. at the superheater outlet, a total of 102 tubes were removed from the three passes of the interdeck superheater.

The superheater performance curve as obtained from checks on the superheater of No. 52 boiler is not flat, as the steam temperature is 40 deg. below the expected temperature of 670 deg. fahr. at 80,000 lb. per hr. steam flow; it checks the expected temperature of 700 deg. at 140,000 lb. per hr. steam flow; and is 17 deg. higher than the expected 708 deg. temperature at 220,000 lb. per hr. steam flow.

Feed water regulation by means of the Copes regulators is satisfactory and approaches very closely the results secured on boilers without water walls. There has been no evidence of priming on this installation.

The performance of the No. 5 unit boilers for the last three months of 1928 has been 84.4 per cent overall efficiency of boiler, superheater, economizer and water walls, with an average steam flow of 191,000 lb. of steam per hr., corresponding to 256.5 per cent (8.6 k-B.t.u. per sq. ft. per hr.) boiler rating.

An efficiency and capacity check run on boiler No. 54 to determine operating performance gave an overall efficiency of 84.9 per cent at 254,500 lb. of steam per hr. equivalent evaporation, and 78.3 per cent without the economizer. This run was of 27 hr. duration, made in accordance with the A. S. M. E. Code. Capacity runs were made for 6 hr. at 352,300 lb. per hr. equivalent steam flow (430 per cent rating) and for 3 hr. at 405,800 lb. per hr. (495 per cent rating). No trouble was experienced in obtaining the high ratings. Table III gives the results of these runs.

A check of the effect of various percentages of excess air upon the degree of superheat for the different types of furnace walls at Hudson Ave. Station is tabulated below.

EFFECT OF PERCENTAGE OF EXCESS AIR ON SUPERHEAT WITH BARE AND COVERED FURNACE WATER WALLS AT HUDSON AVE. STATION

Boiler number	11-34	41-44	51-54
Size, sq. ft.	19,650	22,920	23,760
Furnace construction	Refractory walls	Bare water walls	Bailey water walls
Superheater	Single pass	Single pass	3 pass
Location of superheater	Interdeck	Interdeck	Interdeck
Steam temperature increase per 10% change in excess air, °F.	3.0	7.0	1.5

Check on Boiler No. 54:

Boiler	B. & W. cross drum, 23,764 sq. ft.
Superheater	B. & W. 3 pass interdeck, 3037 sq. ft.
Water Walls	Fuller Lehigh, 1326 sq. ft.
Economizer	B. & W. return bend, 14,975 sq. ft.
Stoker	Westinghouse underfeed, 15 retort, 33 tuyere

STATEMENT BY THE CLEVELAND ELECTRIC ILLUMINATING COMPANY, CLEVELAND, OHIO

Cross-Baffling in Stirling Boilers

Fig. 7 shows a cross baffle installed by the Engineer Company of New York in one of our Class "P" 13-26, 14,460 sq. ft. Stirling boilers. Comparing the operation of this boiler with a similar one having four-pass baffling usually recommended by the B. & W. Co., we find the following:

With the same grade of coal and as nearly as possible the same percentage of excess air, there is no difference in the final temperature of the gases. It has been found possible to increase the capacity some 23 per cent of normal rating to a limit of roughly 300 per cent (10 k-B.t.u. per sq. ft. per hr.) rating. With a cross baffle the water level is not as stable as with the regular baffles.

STATEMENT BY THE CONSOLIDATED GAS, ELECTRIC LIGHT & POWER COMPANY OF BALTIMORE, BALTIMORE, MD.

Radiant Heat Superheaters, Westport Generating Station

In the Westport Generating Station, a total of eight Foster Wheeler radiant heat superheaters are installed in connection with the 10,470 sq. ft. boilers. The first of these, an experimental installation in No. 24 boiler made in January, 1924, marked the first use of a radiant heat superheater in a stoker-fired furnace for central station service. Following two years of experimenting with the first installation, the second superheater was placed in operation in boiler No. 30, January, 1926. This second installation incorporated several changes in design, the major change being the use of forged steel instead of cast steel elements.

The radiant heat superheaters operate in series with convection type superheaters installed above the first boiler pass. Based on the satisfactory performance of the radiant heat superheater installed in boiler No. 30, and further, because the expected increase in the average temperature would effect economies to justify the expense, six additional boilers were so equipped, the latest installation being placed in service in March, 1927.

FIG. 7—14,460 Sq. Ft. Stirling Boiler Showing Cross Baffling. The Cleveland Electric Illuminating Co.

Each superheater is made up of 48 elements of rectangular cross-section, each 5 ft. 4 in. long by 4 in. wide, installed in a vertical position in the furnace bridge wall. Each superheater has a heating surface of 84.5 sq. ft. Steam enters one end of a divided top header, flows vertically down through 24 elements into a common bottom header, thence vertically up through the remaining 24 elements and out the opposite end of the divided top header. Both headers are 10 in. in diameter with walls 9/16 in. thick and are slightly flattened on two opposite sides to allow the entrance of 2 in. No. 9 gage (0.148 in.) nipples connecting the headers to the elements, and for the 2 in. handholes which are necessary for rolling the nipples into the elements and headers. The nipples connecting the headers and elements are about 30 in. long. Both top and bottom headers are supported on spring hangers.

All of the superheaters have forged steel elements with ends forge-welded in, the cast steel elements on the first installation having been replaced by forged steel elements after about two years of unsatisfactory operation. The elements have a wall thickness of about ¾ in., but at the point where the nipples are rolled in, the wall thickness was increased to about 1¾ in. to allow a suitable tube seat for rolling. The tube seat is fitted with two grooves, ¼ in. wide and 1/16 in. deep, of the "Lufkin" type. Each element has a 4 in. x 4 in. x ⅜ in. angle iron welded to the back of the element and midway its length, for resting on cast iron plates built into the bridge wall so as to transfer the weight of the elements from the nipples to the bridge wall.

Between every second nipple at the bottom and every third nipple at the top a box is formed by a section of 8 in. cast iron I-beam, having a ⅛ in. sheet iron plate front and back. This box is filled with long fiber asbestos packing and allows movement of the nipples due to warping of the elements.

Fig. 8 and 9 show the construction at the front and back of the superheaters.

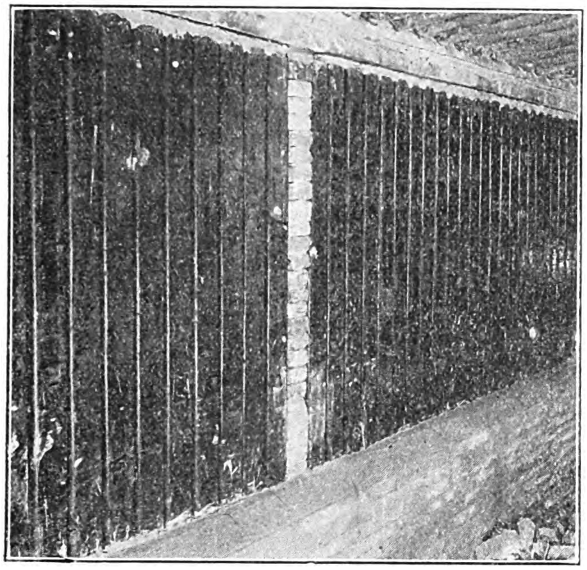

FIG. 8—RADIANT SUPERHEATER, FRONT VIEW, WESTPORT STATION. CONSOLIDATED GAS, ELECTRIC LIGHT & POWER CO. OF BALTIMORE.

Operating Troubles

The troubles which have been experienced with these radiant heat superheaters were, in the main, confined to the initial experimental installation. The cast steel elements used in the first installation were subject to excessive warping. When hot they took a shape convex toward the fire, and when cold, concave toward the fire. The headers were arranged on roller supports in such a manner as to provide for longitudinal expansion, but with no allowance for vertical movement. When the elements warped, it was either necessary that the nipples take up the movement or that the headers move vertically. The nipples proved rigid, with the result that the rolled joint where the nipple entered the element was placed under severe stress, and in several instances actually parted, creating a very troublesome operating condition until the boiler could be taken off the line. A change to spring supports for the headers and an increase in the width of tube seat, where the nipples are rolled into the element, together with the provision of grooves in this tube seat, served to remedy the trouble. The increase in the bearing surface for rolling of the nipples into the elements was very successful, as it had been very difficult to keep these joints tight because of the movement of the elements and the inability to inspect carefully the rolling. The excessive warpage of the cast steel elements was still unsatisfactory and, coupled with the successive appearance of leaks caused by sand holes, finally made it necessary to replace the cast steel elements with others of forged steel.

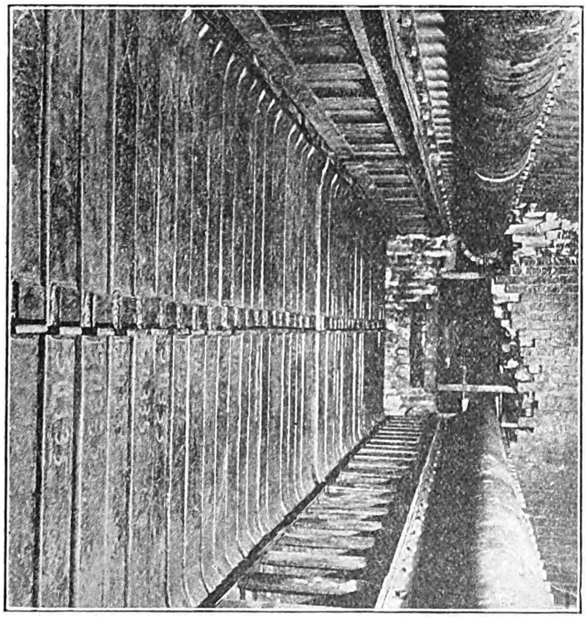

FIG. 9—RADIANT SUPERHEATER, REAR VIEW, WESTPORT STATION, CONSOLIDATED GAS, ELECTRIC LIGHT & POWER CO. OF BALTIMORE.

The illustration of the back of the superheater shows very clearly the individual angle iron supports welded to the back of each element. In the first installation two continuous angles were used, each being rigidly bolted to and supporting 24 elements. This method of support interfered with individual movement of the elements, due to warping, and it was found necessary to change to individual supports for each element in order to allow free movement.

The cleaning of the exterior surface of the superheater presented quite a problem. It was found very important to keep the superheater surfaces clean, as tests definitely showed that there is as much as a 40 per cent reduction in steam temperature rise when comparing a dirty with a clean superheater.

The first installation was provided with what was termed "rosette" type steam soot blowers. The nozzles were installed on the front of and directly attached to the superheater elements, steam being fed to the nozzles through cored holes in the cast steel elements. There were six nozzles or heads, one located at the center of every eighth element, which directed steam in all directions along the surface of the superheater. This type of soot blower proved unsatisfactory due to stoppage of the holes in the nozzles and its inability to remove slag.

A wall type of steam soot blower, consisting of stationary nozzles located at each side of the superheater, was also tried and proved unsuccessful. In addition to the soot blowers, steam lances were also tried but did not prove satisfactory. All efforts to use steam for cleaning the superheater failed. Sand-blasting was tried, with very satisfactory results, and is now being used on all of these superheaters. There has been no evidence of harmful effect on the elements because of the sand-blast. A period of about 8 min. with two men is required for cleaning.

As previously mentioned, the troubles which have been experienced were practically limited to the initial experimental installation. All of the radiant heat superheaters installed are now operating with very little trouble and require a minimum of attention from the operating forces.

STATEMENT BY THE DETROIT EDISON COMPANY, DETROIT, MICH.

Boiler Units at Delray Power House No. 3

The initial installation in the new Delray Power House No. 3 comprises 5 boiler units, each consisting of a screen boiler, a main boiler, a superheater, an economizer and an air preheater. This equipment is now being installed and will not be completed until the latter part of 1929.

These boiler units will be operated in conjunction with single end underfeed stokers, each capable of burning efficiently 34,000 lb. of coal per hr.

Screen Boiler

The screen boiler, Fig. 10, consists principally of a 54 in. o. d. steam and water drum 33 ft. 10 in. long, built from 2-in. plate, with complete water screening for all fire faces of the furnace walls and a slag screen for the exit gas passage. All pressure parts are built for 470 lb. operating pressure.

Each side wall is an independent unit, designed for recirculation between the top and bottom headers. Water flows from the screen drum to the lower headers through

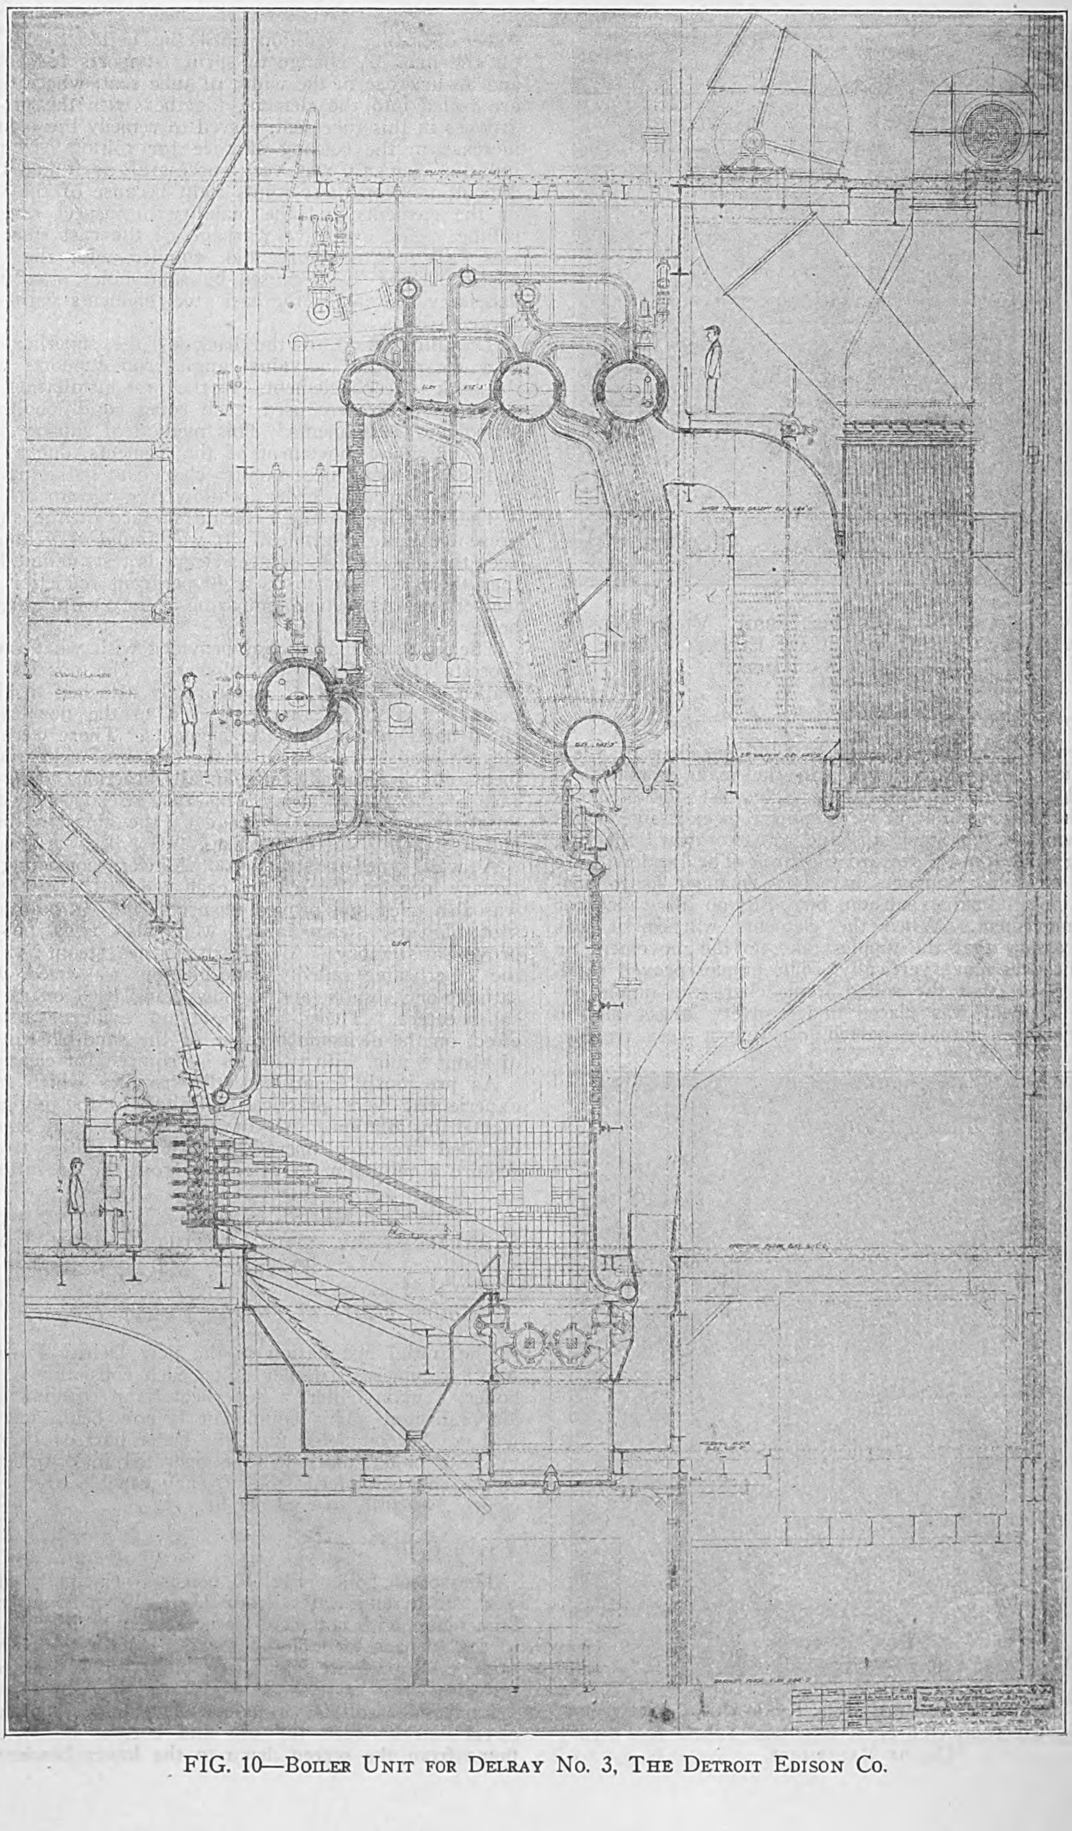

FIG. 10—BOILER UNIT FOR DELRAY NO. 3, THE DETROIT EDISON CO.

four 4 in. o. d. make-up tubes of No. 6 B.W.G. (0.203 in. thick), and steam is taken off the upper header through six 4 in. o.d. riser-tubes of No. 6 B. W. G. (0.203 in. thick) and delivered to the screen drum. Each side wall has forty-five 3¼ in o. d. wall tubes of No. 5 B. W. G. (0.220 in.) and eighteen 3¼ in. o. d. recirculating tubes of No. 5 B. W. G. (0.220 in.). Both upper and lower headers are 11¾ in. o. d. forged steel drums of 1⅜ in. thickness. All tubes within the furnace are on 6 in. centers.

The front wall is continuous with a combustion arch terminating in the screen drum. The water flows directly from the screen drum to the front wall header through twenty-four 3¼ in. o. d. tubes of No. 6 B. W. G. (0.203 in.). The wall has fifty-two 3¼ in o. d. wall tubes of No. 6 B. W. G. (0.203 in.). The header is a 11¾ in. o. d. forged steel drum of 1⅜ in. thickness.

The rear wall is continuous and in series with the slag screen which crosses the gas outlet and terminates in the steam drum. The rear wall lower header receives its water from the screen drum through two 12 in. o. d. outside pipes (one on each side of the screen boiler) bolted to the flanged ends of the header. The rear wall tubes terminate in an upper header accommodating the slag screen tubes thereby completing the circuit. The wall has fifty-two 3¼ in. o. d. wall tubes of No. 6 B. W. G. (0.203 in.), and the slag screen has the same number of tubes of the same thickness. The lower header is a 13⅜ in. o. d. forged steel drum of 1 in. thickness; the upper header is a 11¾ in. o. d. forging of ⅞ in. thickness.

The lower portion of the side walls, the lower portion of the rear wall and the entire front wall and arch will be covered with Bailey blocks, the exposed Bailey furnace wall surface being distributed as follows: Two side walls approximately 330 sq. ft., front wall approximately 808 sq. ft., rear wall approximately 312 sq. ft. The bare tube surface in the furnace is distributed as follows: Two side walls approximately 640 sq. ft., rear wall approximately 364 sq. ft. and the slag screen approximately 1040 sq. ft. Where the Bailey furnace wall construction terminates in the side walls and the rear wall, a refractory wall continues and completes the wall construction. The tiles are in close contact with half of the wall tubes, leaving the bare portion of the tubes facing the furnace.

The screen boiler is a complete self-contained unit, having its own feed water supply and a water circulation system entirely independent of the main boiler. This boiler delivers its steam through two 8 in. pipes to a superimposed 11¾ in. o. d. header located above the main boiler. From this header the steam is distributed to the rear drum through twenty-six 3¼ in. o. d. tubes of No. 7 B. W. G. (0.180 in.). The screen drum is provided with two blow-off connections, one in each end of the drum.

Main Boiler

The main boiler is a 4-drum, Stirling type water tube boiler, 53 tubes wide, having one front steam drum 42 in. diameter, 28 ft. long, built from 1 15/16 in. plate, one middle steam drum and one rear steam drum, both 48 in. diameter, 28 ft. long, built from 2 3/16 in. plate, and one mud drum of the same dimensions as the middle and rear steam drums. All tubes are 3¼ in. o. d. No. 7 B. W. G. 0.180 in.).

The boiler has approximately 23,900 sq. ft. of effective heating surface and is designed for 455 lb. working pressure.

Saturated steam from the screen boiler is introduced into the rear drum where it mixes with the steam from the main boiler. Steam is taken off the top of the rear drum and introduced into the superheater inlet header through forty-three 3¼ in. o. d. tubes, No. 7 B. W. G. (0.180 in.). The mud drum is provided with one 2½ in blow-off connection at each end.

Superheater

The superheater is of the multiple loop type and has approximately 4900 sq. ft. of heating surface arranged as shown in Fig. 10. It is designed for 455 lb. working pressure, 725 deg. fahr. Both inlet and outlet headers are 28 ft. long. The inlet header is 11¾ in. o. d., the outlet header is 13⅜ in. o. d. There are fifty-two 2 in. o. d., No. 8 B. W. G. (0.165 in.) tubes connecting the headers, the continuous one-piece length being obtained through the medium of resistance electric welding. The steam is taken off the superheater through two 12 in. steam pipes bolted to the flanged ends of the superheater outlet header. The design of the superheater does not permit of draining.

Economizer

The economizer is of the horizontal bare tube, return bend type having approximately 6032 sq. ft. of heating surface designed for a safe working pressure of 555 lb. The inlet and outlet headers are 7 in. square flanged at one end for 8 in. inlet and outlet connections. The economizer is 24 tubes wide by 20 tubes high by 24 ft. exposed length, tubes being 2 in. o. d., No. 6 gage (0.203 in.).

The amount of surface in the economizer is of sufficient size to absorb enough heat so that, with an exit gas temperature of 350 deg. fahr. at the maximum coal burning rate, the temperature of the air leaving the preheater will not exceed 350 deg. fahr.

Air Preheater

The air preheater is of the vertical tube type having approximately 30,200 sq. ft. of heating surface. It has 30 rows of 64 tubes, 23 ft. 8½ in. long, 2½ in. o. d., No. 11 gage (0.120 in.). Gas from the boiler enters at the bottom and leaves at the top. The air enters at the top, and after passing crosswise of the bank of tubes twice, leaves at the bottom. The preheater is designed to preheat the air for combustion to a maximum temperature of 350 deg. fahr. at the maximum coal burning rate.

STATEMENT BY THE DUKE POWER COMPANY, CHARLOTTE, N. C.

Buck Steam Station

The equipment in the Buck Steam Station consists of two 35,000 kw. turbines and four 26,600 sq. ft. pulverized coal-fired boilers. Steam is delivered from these boilers at 425 lb., 700 deg. fahr. In the first twelve months 429,370,000 kw-hr. were generated, which is an indication of the reliability of the plant, including the boilers. In normal operation three of the boilers carry full 70,000 kw. load, one boiler being out for routine inspection and maintenance. The plant has not yet been in operation a sufficiently long time to determine whether the availability of the boilers is equal to that of the turbine or not.

The boilers have at times evaporated as high as 340,000 lb. of steam per hr. The superheater delivers steam varying in temperature with rating from 670 to 730 deg. fahr. The feed to the boiler is controlled by thermostatic type feed water regulators with individual excess pressure valves in each boiler feed line. This combination is entirely satisfactory under normal load changes, but in the case of total loss of load, water disappears from the gage glass, and if the boiler is immediately brought back to rating, there is a decided tendency to prime. When the plant was originally started, some slight trouble was had with burning of superheater tubes, which was attributed to the poor arrangement of baffling in the superheater drums, coupled with the tendency of the boilers to prime at sudden increases of rating, although a concentration of but 5 to 7 grains per gallon (85.75 to 119.85 p.p.m.) total solids was being maintained in the water. The baffling in both the boiler drums and superheaters was changed, eliminating the tendency to prime at high rates of evaporation and completely stopping trouble with the superheater.

STATEMENT BY THE EDISON ELECTRIC ILLUMINATING CO. OF BOSTON, BOSTON, MASS.

Edgar Station

One of the main defects in the design of many stations is the ratio of the kilowatt capacity of the steam generating units as compared with the capacity of the turbine-generator units. The capacity of the boiler units has always lagged behind the capacity of the turbine-generator units and has resulted in a much higher cost for the boiler plant. We should strive to approach as nearly as possible the ideal arrangement, where the capacity of the steam generating unit matches the capacity of the turbine-generator unit. The trend of design is in this direction.

In the past, boilers have been operated far below the ratings that would result in the highest commercial economy. Much data have been obtained during the past few years on the maximum capacity of boiler sections of various designs, but the data are not complete and every effort should be made to obtain this information so that the most economical steam generating unit can be designed.

In the design of the steam generating unit an attempt should be made to distribute the heat-absorbing surface between the boiler, superheater, reheater, economizer, air heater and water-cooled furnace walls, so as to obtain the lowest first cost and the overall efficiency that is justified by the operating conditions. This balance has been obtained very seldom in the past.

Water-cooled furnace walls have come into general use during the past few years, and operating troubles have shown that the heat-absorbing capacity of the walls of the various designs under various operating conditions is not fully known. Since this type of equipment has become such an essential part of the steam generating unit, both the manufacturers and the users of this equipment should cooperate and obtain all the essential data necessary to permit of safe and economical design. The present designs are far from being ideal.

The regenerative cycle has made the air heater an essential part of steam generating unit design. In fact, for certain operating pressures the air heater apparently cannot be omitted without a large sacrifice in commercial economy. Accurate data as to the relation of combustion air temperature to furnace temperature are needed. Information as to the maximum air temperature that can be utilized with various types and makes of fuel-burning equipment is lacking.

In other words, recent developments have been so revolutionary that accurate information as to the relation of the various pieces of equipment that go to make up a steam generating unit is lacking. As a result, it is probable that the designs now being utilized do not have the proper relation between the various parts.

Fig. 11 shows the developments that have been made in the design of steam generating units utilizing cross-drum boilers for pressures of from 1200 to 1400 lb. during the past five years. Let us compare them item by item.

The first two designs have 48-in. forged steel drums with dry pipes of the customary design. The third design has a 52-in. drum without a dry pipe. The saturated steam is taken from this drum at 12 different points, and the result is a material increase in the effective size of the boiler drum. This company does not agree with the advocates of smaller boiler drums. It is believed that the capacity of the boilers should be increased per section, and that the boiler drum should be of adequate size. Furthermore, by delivering the steam to the superheater header at 12 different points along

its length, much better distribution is obtained and the effective size of the superheater inlet header is materially increased. Those who have had trouble with the distribution of steam in superheater headers can readily appreciate the advantages of this change in design.

The first boiler is constructed of 2-in. tubes throughout, and due to the tube size the section headers are perpendicular to the boiler tubes. The tubes are 15 ft. long and arranged in two banks. The second design utilizes 3¼-in. tubes in the lower deck and 2-in. tubes in the upper deck. The 3¼-in. tubes permit the use of vertical headers for the lower bank, which in turn allow the use of tubes 19 ft. long. This construction materially improves the shape of the furnace and gives a much better design of boiler. Quite a radical step is taken in the third design. The upper bank of boiler tubes is omitted, and the boiler made single-pass instead of three-pass; the tubes are 20 ft. long. Additional economizer surface is installed to do the work formerly done by the upper bank of boiler tubes.

The superheater in the first design is four-pass across the width of the boiler and is designed for 700 deg. fahr. total steam temperature. In the second design the superheater is three-pass across the boiler and is designed for 733 deg. fahr. The superheater in the third design is four-pass from the bottom to the top and is designed for 750 deg. fahr. As will also be noticed, in the third design the superheater headers are entirely removed from contact with the flue gases.

The 370-lb. steam reheaters in the first two designs are located above the first and second passes of the boilers below the horizontal circulators. In the third design the reheater is located above the boiler beside the economizer with a consequent material improvement in accessibility. The reheater in the first design is designed for an outlet temperature of 700 deg. fahr., and in the second and third designs for 750 deg. fahr.

The first design has a steel tube economizer with square boxes connecting the ends of the tubes. The second and third designs utilize both economizers and air heaters, and the economizers are of the return bend type. In the third design the economizer tubes are hairpin shaped, which reduces the number of joints to approximately one-half that in the first two designs.

The use of air heaters in the second and third designs requires the installation of water-cooled walls on three sides of the furnaces.

Many other refinements have been made in the design which do not show in the picture. The net result of these changes in design has been a lower cost per unit of capacity and a further reduction in the building space required per kw. of station capacity without a sacrifice in overall efficiency.

Table IV shows the distribution of surface between the various pieces of equipment that go to make up the steam generating units shown in Fig. 11. As can be seen, the area of the boiler heating surface has been reduced 54 per cent, while the steam generating capacity has been doubled. However, the total heating surface has been increased approximately 67 per cent. It simply means that an attempt has been made to distribute the heat-absorbing surface between the boiler, economizer and air heater so as to obtain the most economical combination for the steam generating unit.

Capacity in lb. per hr	143,000	250,000	300,000

Soot Blower Test

The object of the test was to determine the effect of the operation of soot blowers upon the performance of a boiler, superheater and economizer, when operated for a prolonged period under normal station conditions.

Considerable thought was given to the selection of the factors whose variation might be used to measure the effect of the soot blower operation. The combustible consumed per kw-hr. is the best measure of performance; however, the errors entering into its determination might be greater than the entire difference caused by the soot blowers. For instance, the saving in coal which can be attributed to the use of soot blowers would only amount to a small per cent, whereas the effect of errors in weighing coal and of fluctuations in moisture content, ash content and volatile combustible might easily exceed this amount. It is, therefore, apparent that some other standard of comparison should be adopted.

Soot blowers are designed to increase the heat absorbing power of the boiler, superheater and economizer tubes by keeping them free from soot. Therefore, their use should reduce the flue gas temperature at the economizer outlet and increase the steam temperature at the superheater outlet. The fluctuations in flue gas temperature and in superheated steam temperature were therefore selected for comparison. Both of these can be determined within 1 per cent and both have a direct bearing upon the quantity of combustible consumed.

Another object in using soot blowers is to keep the tube surfaces free from hard slag, thereby reducing the draft losses and, under certain conditions, increasing the time between shut-downs for thorough cleaning.

The object of the tests may, therefore, be more specifically stated as the effect of soot blower operation upon flue gas temperature, steam temperature and draft loss.

The tests were run on No. 4 boiler at the Edgar Station, which was operated by the regular boiler room forces at normal variations in steam output.

No. 4 boiler, Fig. 12, is a B. & W. cross-drum boiler operating at 375 lb. gage pressure. It is equipped with an interdeck superheater and an economizer; is stoker fired and operates with forced and induced draft.

The soot blowers are supplied with saturated steam at boiler pressure from both ends of the superheater inlet header. There are ten pairs of horizontal elements in the boiler and superheater, designated by the letters A to J, and located as shown on the cross-section. The economizer contains ten single vertical elements.

The boiler instruments record steam pressure, steam flow from the boiler, gas flow to the boiler, and temperatures of flue gases and feed water at the inlet and outlet of the economizer. Draft and steam temperatures were recorded hourly by the station operators, the former by an Ellison draft gage and the latter by a thermocouple. All instruments were calibrated at the beginning and at the end of each period of the test.

Before the tests the boiler, superheater and economizer were thoroughly cleaned. They were then inspected and all parts found commercially clean and in proper condition for the test.

The boiler was put on the line on April 6, 1928, and operated under station load conditions 42 days until May 17, all soot blowers being operated three times each day. Units A, B, C, D, E and F were operated for three revolutions and the other units for one revolution at each blowing period. At the end of this period the boiler was again inspected. As soon as it could be shut down, on June 9, it was again thoroughly cleaned and inspected to insure that its condition was the same as before the start of the test. It was then put on the line June 14 and operated for thirty days without soot blowers under station load conditions. At

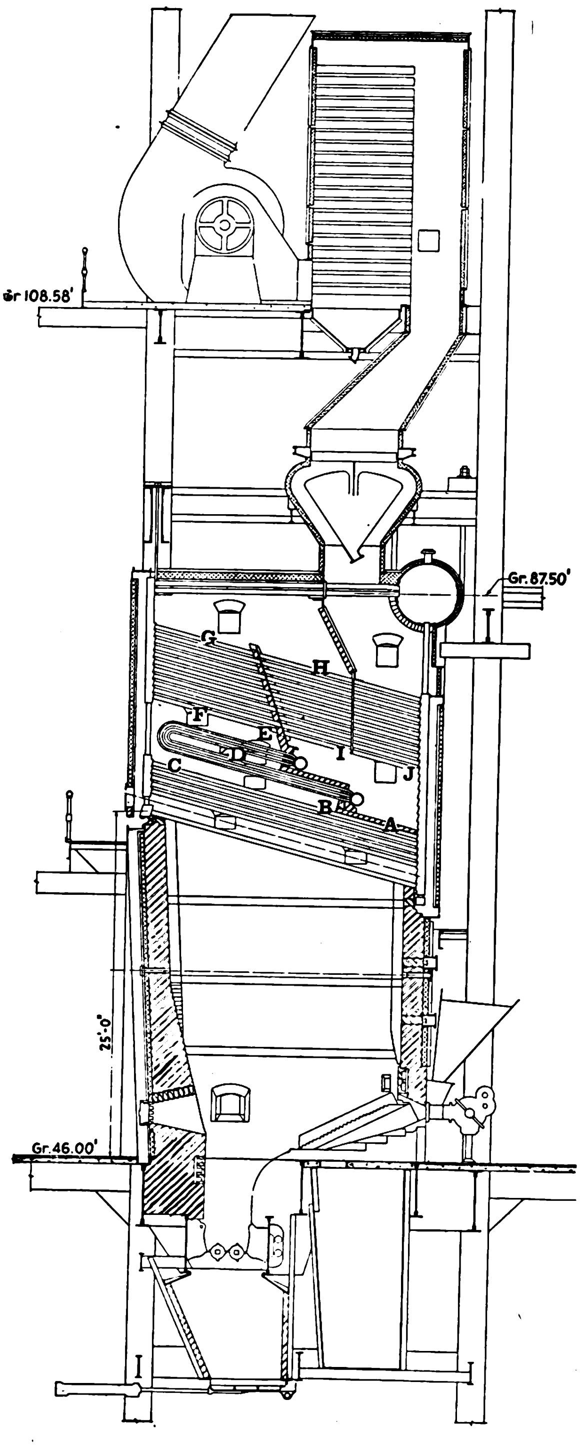

FIG. 12—19,743 SQ. FT. BOILER NO. 4, EDGAR STATION, THE EDISON ELECTRIC ILLUMINATING CO. OF BOSTON.

the end of this period it was shut down and inspected again.

At the completion of the tests a large amount of data was available, reflecting the effect of many varying conditions. Inasmuch as the two most important of these, viz., load and excess air, might affect the boiler performance far more than the soot blower operation, they were eliminated by selecting only readings at which they were substantially the same.

Fig. 13, 14 and 15 show the change in superheated steam temperature and flue gas temperature at the economizer outlet for three conditions during the test.

Fig. 13 is a comparison based on a steam output of 120,000 to 125,000 lb. per hr. and excess air of 35 to 40 per cent. It shows the steam superheat maintained constant at 670 deg. fahr. during thirty days of operation using soot blowers, and dropping from 670 to 630 deg. for an equal period when the soot blowers were not operating, a difference of 40 deg. in favor of the soot blowers. It also shows the flue gas temperature at the economizer outlet maintained at 277 deg. while operating soot blowers, and increasing from 280 to 292 deg. during the period when soot blowers were not operating; a gain of 12 deg. in favor of soot blower operation.

Fig. 14 is a similar comparison for steam outputs of 145,000 to 150,000 lb. per hr. and excess air of 35 to 40 per cent; it shows a reduction in steam temperature of 10 deg. while using soot blowers and of 40 deg. when not using soot blowers, a gain of 30 deg. in favor of soot blower operation. The gas temperature at the economizer outlet shows a reduction of 7 deg. while soot blowers were operated and a rise of 8 deg. when they were not operated, a gain of 15 deg. in favor of soot blower operation.

Fig. 15, which is based on steam outputs from 165,000 to 170,000 lb. per hr. and excess air of 30 to 35 per cent shows a drop of 7 deg. in steam temperature while operating them, a gain of 35 deg. in favor of soot blower operation. However, the gas temperature shows an increase of 10 deg. while operating soot blowers and an increase of 12 deg. while soot blowers were not operating, a gain of 2 deg. in favor of soot blower operation.

These curves are not entirely consistent, so that it is possible to draw only approximate conclusions from them. However, based on a study of the curves and of a large amount of uncorrelated data obtained during the tests, we are of the opinion that the use of soot blowers during a period of thirty days of operation at 120,000 lb. of steam per hr. would retard the drop in superheated steam temperature by 30 deg. or by 1 deg. per day, and that it would also retard the rise in flue gas temperature by 15 deg. or by ½ deg. per day at a load of 120,000 lb. of steam per hr. Therefore, our subsequent calculations have been based on these figures and upon a steam output of 120,000 lb. of steam per hr., the average output of boilers No. 1 to 4 at the Edgar Station during the three months of the test.

Fig. 16 shows the daily net saving in tons of coal each day by the use of soot blowers, based on the assumption that the retarded change in superheat and flue gas temperature takes place at a uniform rate. This saving takes into consideration the coal equivalent of the steam which was required to operate the soot blowers. The curves show that for several days after a clean boiler is placed in service, the cost of the steam required to operate the soot blowers exceeds the saving obtained by their operation. Considering all soot blower elements this period is 7 days, after which there is a gain each day by using soot blowers. This sheet also shows separately the saving from the elements which clean the superheater only and the saving from all other elements in the boiler unit. The gain from increased superheat offsets the steam consumption of the blowers on the fifth day while twelve days are required before the saving of the other elements equals their steam consumption.

Fig. 17 shows the cumulative savings due to the operation of superheater elements and to all other elements. It shows that it takes ten days of operation before the saving due to higher steam temperature is sufficient to offset the steam used by the soot blower elements and twenty-three days before the lower flue gas temperature offsets the steam consumption of the other soot blower elements.

Assuming a period of thirty days of operation between thorough cleanings of the boiler unit, the fuel saving due to operating the superheater soot blower elements would amount to 20 tons of coal for the period, while the saving due to all other elements would amount to about 2 tons of coal. These indicated savings are also subject to further reduction by the cost of maintaining the soot cleaning equipment and by the fixed charges on its initial cost.

An examination of the data of draft losses through the boiler for both operating conditions gives no evidence that soot blower operation makes any change in boiler draft loss.

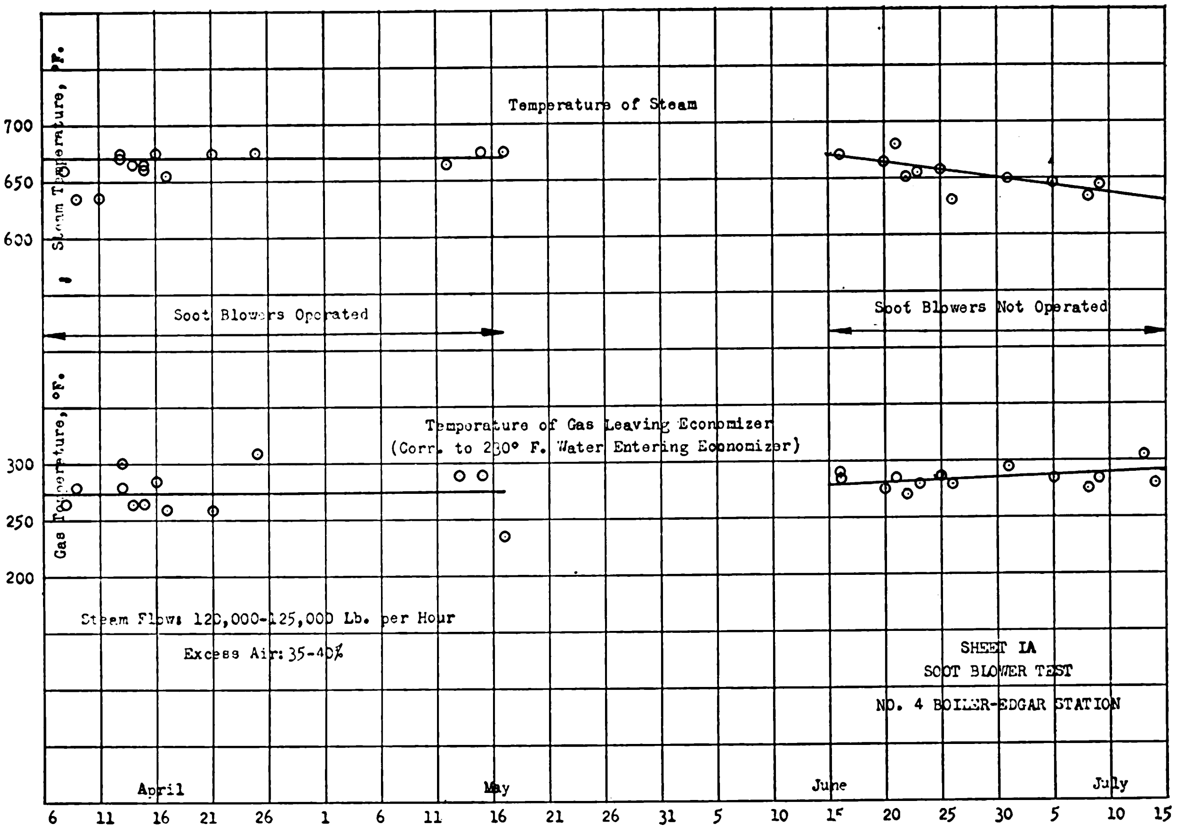

FIG. 13—Effect of Soot Blowers on Gas and Steam Temperatures, 125,000 Lb. per Hr. Rating, Edgar Station.

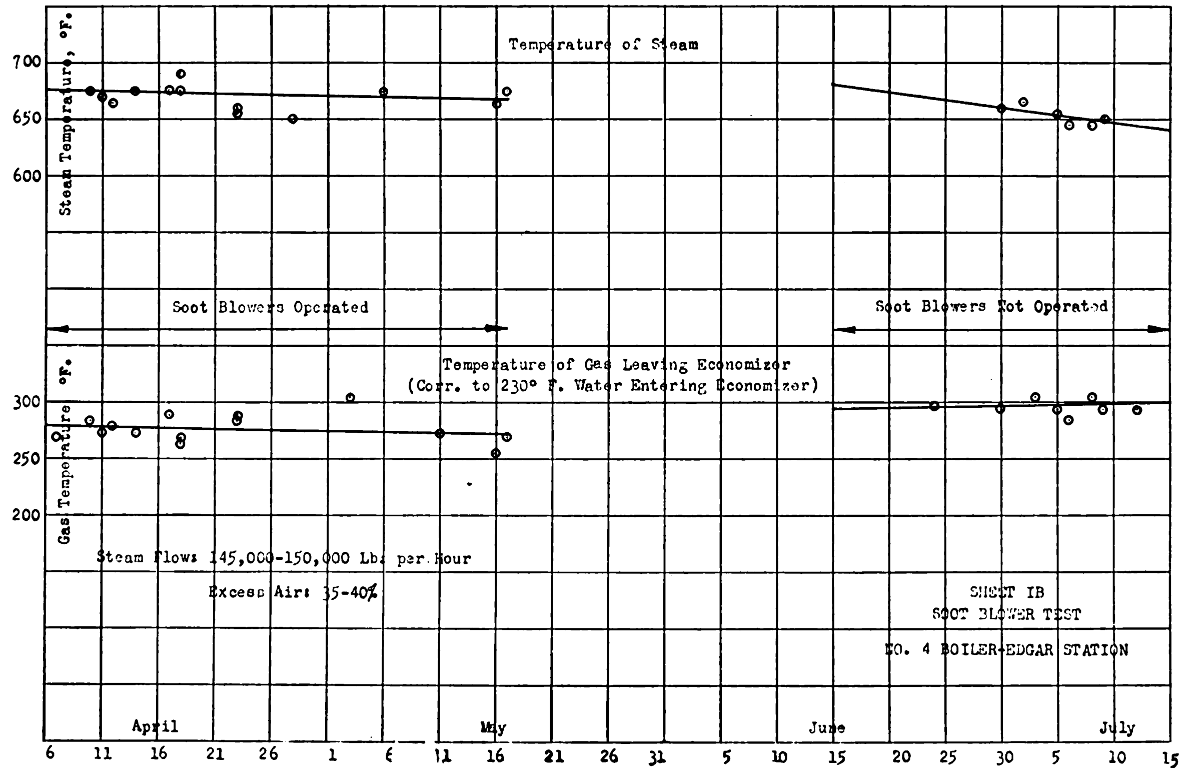

FIG. 14—Effect of Soot Blowers on Gas and Steam Temperatures, 150,000 Lb. per Hr. Rating, Edgar Station.

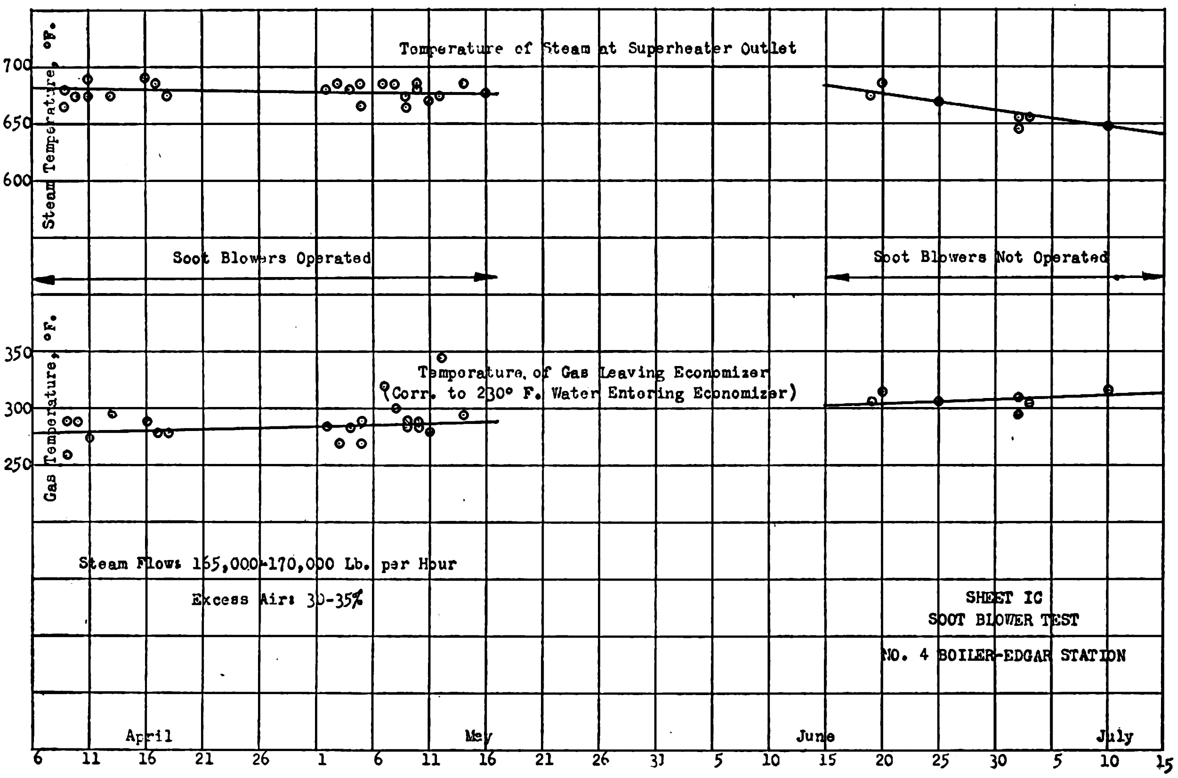

FIG. 15—Effect of Soot Blowers on Gas and Steam Temperatures, 170,000 Lb. per Hr. Rating, Edgar Station.

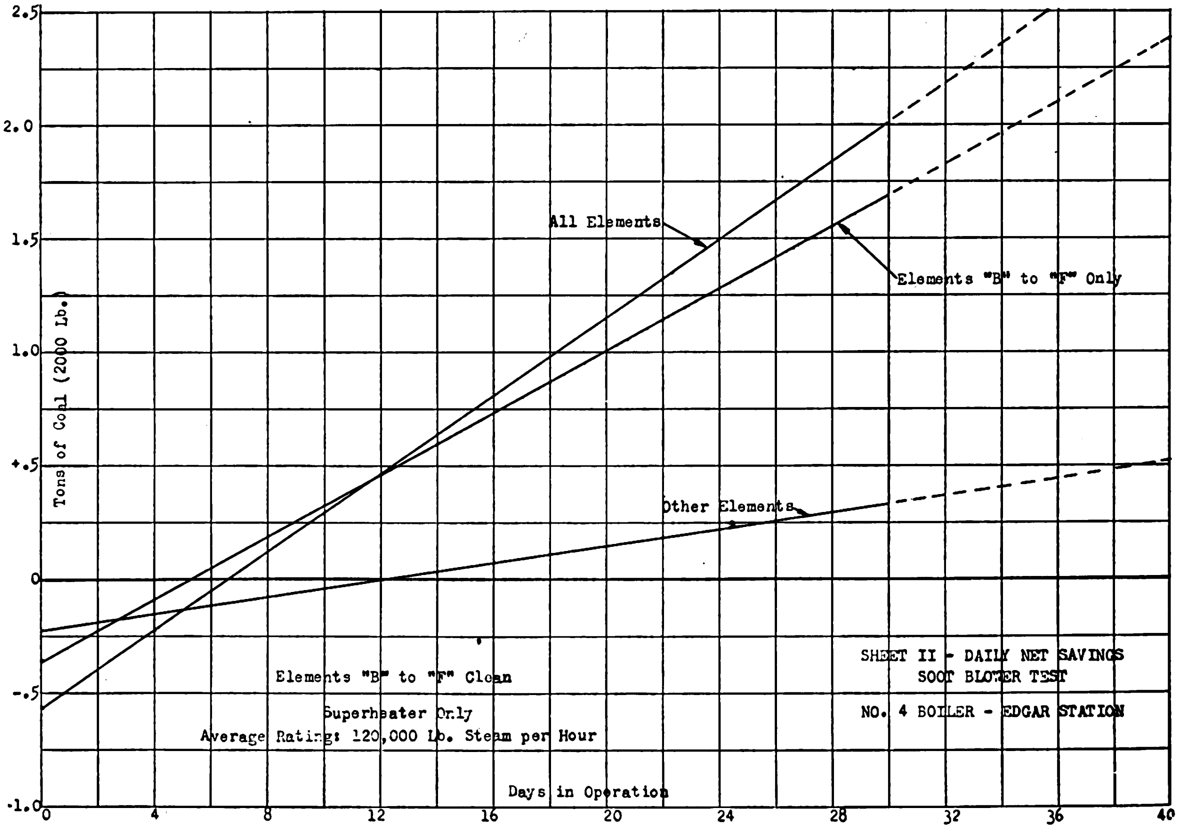

FIG. 16—Daily Net Saving Due to Use of Soot Blowers, Edgar Station.

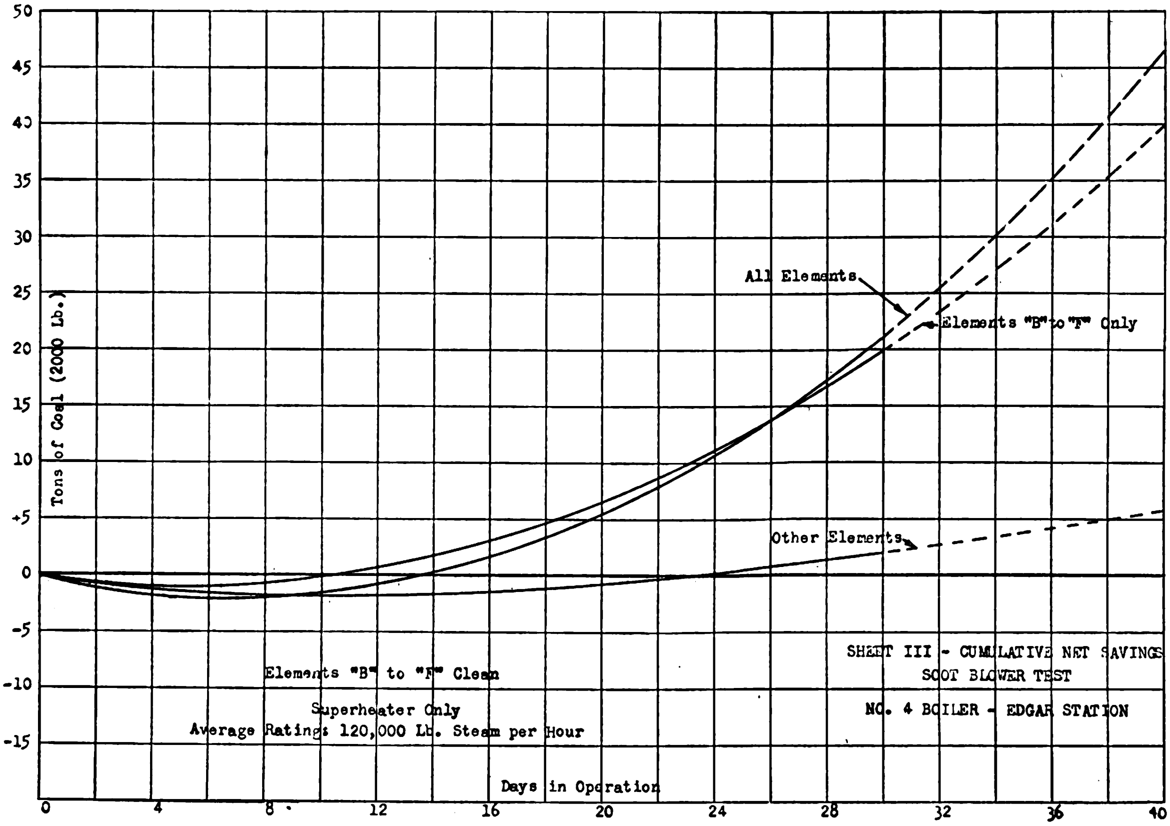

FIG. 17—CUMULATIVE NET SAVING DUE TO USE OF SOOT BLOWERS, EDGAR STATION.

The following conclusions can be drawn from the test:

1. Soot blower operation results in an increase in steam temperature at the superheater outlet, the gain from which is substantially greater than the steam consumption of the soot blower elements.
2. It also results in a reduction in the temperature of flue gases leaving the boiler unit, the saving from which is but little greater than the steam required to operate the soot blower elements.
3. Soot blower operation has a negligible effect upon draft loss.
4. The use of soot blowers appears to reduce the amount of slag deposited on the lower deck of boiler tubes. However, the slag deposit when soot blowers were not used was not sufficient to cause the boiler to be taken out of service for cleaning. It is possible, however, that higher boiler ratings might alter this condition.
5. These conclusions might have been somewhat more favorable to soot blower operation had the elements been operated less frequently, or for a fewer number of revolutions, thereby reducing their steam consumption.

STATEMENT BY THE GREAT WESTERN POWER COMPANY OF CALIFORNIA, SAN FRANCISCO, CAL.

San Francisco Steam Plant

The Great Western Power Company of California has under construction a new reserve steam plant in southeast San Francisco, with an initial capacity of 35,000 kw. and ultimately at least three more units designed for unusually low annual load factors and quick load "pick-up" conditions.

This company's system and that of the San Joaquin Light & Power Company, both under the same management, are tied together by a transmission line. The former serves part of San Francisco and nearby cities and towns and others northeastward, principally from the Caribou, Bucks Creek and Big Bend hydroelectric plants on the Feather River. The Caribou plant and its 1,300,000 acre feet of storage are farthest upstream, about 200 miles from San Francisco. The San Joaquin system serves the valley south to Bakersfield about 300 miles from San Francisco.

The hydro capacity of the combined systems is now about 343,000 kv-a., the steam capacity about 87,000 kv-a., not including the capacity of the new plant, or a total of 430,000 kv-a. This new steam plant is near the end of the transmission lines, terminating through 11 mile long bay cables from the step-down station at Oakland, with one small, old steam plant in Oakland and another in the northern part of San Francisco for reserve.

The hydro plants are of sufficient capacity and have sufficient water storage to require very little output of the steam plants, the estimated average annual load factor of the new steam plant being about 5 per cent. The steam plant capacity must be immediately available to prevent interruptions in service when submarine cables are damaged by dragging ships' anchors, or when other transmission line outages occur. The steam plant is designed to take on almost instantly the San Francisco load up to the full capacity of the turbine-generator.

Specially designed Hedges-Walsh-Weidner boilers have been provided. For the first turbine there will be two 22,250 sq. ft. cross-drum boilers, each 56 sections wide, 13 tubes high, 24 ft. long. Each boiler will be equipped with a 72-in. main drum, about 40 ft. long. Eleven feet above the main drum is an auxiliary drum 36 in. in diameter and 30 ft. long, connected to the main drum through 45 4-in. tubes. This auxiliary drum has two steam purifiers connecting to the two 10-in. outlets which go to the convection type superheaters located above the tube bank. The boiler design pressure is 450 lb., and the initial total temperature 625 deg. fahr. The boilers will have initially a capacity of 300,000 lb. per hr. each and an ultimate capacity of 450,000 lb. per hr. each. By the addition of radiant surface to superheaters, the total temperature can be later increased to 725 or 750 deg. fahr. There will be no air heaters or economizers initially, but space and provision has been left for adding them when capacity increase becomes desirable. The boilers will be oil-fired with 20 main burners and 9 pilot burners, arranged to operate over a range of 800 to 30,000 lb. of oil per boiler. Furnaces will be of the air-cooled type, 33 ft. wide and with a total volume of 17,400 cu. ft., designed for the addition of water walls when capacities are increased and for the possible ultimate use of powdered coal.

The very wide boiler gives relatively low velocities of steam leaving the tubes and entering the drum, and the relieving area in the 72-in. drum is large compared to practice for more usual conditions. These features, combined with the dry drum and steam purifiers, are specially provided for preventing water from being carried over to the turbine.

Under normal conditions, the main turbine and house turbine will operate as synchronous condensers for power factor correction with sufficient cooling steam going through the main unit to prevent injurious heating. Special overload valves have been provided on the turbine to permit development of full capacity with steam pressures as low as 235 lb. gage, dry and saturated steam, although the machine is of 400-lb. design. It is expected that the unit will be able immediately to take on any load up to its capacity, and that the boilers will be steaming at required capacity within a few minutes after the assumption of load with a steam pressure drop of 125 lb. During this interval, due to the particular design of part of the turbine, the steam pressure can be permitted to drop 125 lb., and in doing so utilize the large water storage capacity as an accumulator to make steam while the boiler is being brought from stand-by condition of say 5 per cent load to required steam output. Special automatic equipment will be provided to synchronize and adjust the various auxiliaries which will have to be started or increased in capacity during this period.

STATEMENT BY THE MILWAUKEE ELECTRIC RAILWAY & LIGHT COMPANY, MILWAUKEE, WIS.

Radiant Superheaters

Approximately two and one-quarter years' operation of the high-pressure installation at the Lakeside plant, a total of 14,000 service hours, has proved the use of radiant surfaces for the 1300-lb. superheater and 300-lb. reheater to be a commercial success. Heat transfer has averaged 45,000 B.t.u. per sq. ft. per hr., and temperatures have been as desired. The average outlet temperatures during the major portion of the operating time are:

	1927	1928
Superheater outlet temp., deg. fahr......	733.5	728.6
Reheater outlet temp., deg. fahr..........	713.1	708.3

Both reheater and superheater temperatures have averaged 750 deg. for over 100 hr. operation. There is no doubt that the radiant superheater affords unlimited opportunities for high steam temperatures.

Reliability of the superheater and reheater elements has been satisfactory, for at no time has an enforced outage been occasioned by failures. Outside of reducing the superheater surface 3 per cent, no concern has been caused by the high-pressure superheater. Metal temperatures and stresses are such in the high-pressure installation, due to high mass flow of the dense high-pressure steam and due to its high specific heat giving good heat transfer characteristics, that creep limits of the high carbon-steel employed are not exceeded.

Radiant vs. Convection Superheaters

For a high-pressure installation, consideration of the radiant superheater characteristics will show it more desirable than the convection superheater because of its rising temperature characteristic at lowered ratings. Reference to Fig. 18 shows that although the superheater outlet temperature increases 50 deg. when lowered to 40 per cent maximum rating, first-stage turbine temperatures vary less than 10 deg. and are almost identical at low loads and high loads. Consideration of the Joule-Thomson effect of lowering temperatures when throttling high-pressure steam explains this condition and points out the desirability of using superheaters with radiant characteristics if maximum gain of high steam temperatures is desired at high pressures. Even the flat temperature characteristic of the combination radiant and convection superheater is undesirable, and the drooping characteristic of the convection superheater causes a 100-deg. drop in first-stage temperature of a high-pressure turbine from full to zero load.

Uniform first-stage temperatures result in uniform stage temperatures throughout the machine if the unit is operating in compound with a condensing turbine. There is no doubt but that this characteristic of uniform steam temperature throughout the turbine is desirable when running with the small clearances found necessary in high-pressure machines.

High superheat temperatures at low loads cause no concern as regards superheater metal temperature. The actual metal temperature is the criterion of safety—not the steam temperature. At full load the temperature difference between the steam and metal is about 250 deg. At half load this temperature difference decreases approximately to 200 deg. In spite of 50 deg. higher steam temperature, the internal metal temperature is thus no higher at low ratings. Temperature drop through the metal decreases, and the external metal temperature is actually lower at reduced ratings.

There being no heat transfer through the metal piping and fittings, their temperature is essentially that of the steam, and they present no problem when subjected to the higher temperatures attendant with low ratings, providing they are purchased originally with proper specifications. Creep phenomena limit the safe steam temperatures only in metals considerably higher in temperature than the steam. Close clearances demand careful consideration of temperature at the turbine, but the problem presented by intermediate piping and fittings is much less in degree.

Consideration of the above points indicates that the radiant superheater is desirable for high-temperature, high-pressure installations. Used in combination with a convection reheater, and the high-pressure turbine operating in compound with a low-pressure one, the overall combination results in remarkably uniform steam temperatures in both turbines over a wide range of load. The Joule-Thomson throttling effect at low pressures is greatly less than at 1300-lb. pressure, as shown by Fig. 19, rendering a flat temperature curve characteristic fairly acceptable for the low-pressure turbine. Use of the combination radiant superheater and convection reheater plan, in most cases, greatly facilitates and improves the overall unit design.

From the experience with the radiant-superheater high-pressure installation, there seems little doubt but that the radiant design will be retained in the future, and will be found increasingly desirable as higher temperatures are used.

STATEMENT BY THE NEBRASKA POWER COMPANY, OMAHA, NEB.

Boiler Outage

Four boilers are operating at 300 lb., and eight 5000 sq. ft. boilers are operating at 200 lb., being connected with the high-pressure boilers through a reducing valve. The following data will give the most concise picture of the operation of the 300-lb. boilers during the year 1928:

Boiler Number.............	20	21	22	23
Year installed	1920	1922	1922	1924
Water-heating surface, sq. ft.	13,828	13,828	13,828	18,923
Total steaming hr...........	8,173	7,338	5,783	8,315
Average steaming rate, k-B.t.u./sq. ft./hr.	6.5	6.7	6.9	6.1
Total hr. banked...........	138	1,057	2,496	20
Total service, hr............	8,311	8,395	8,279	8,335
Service hr., % of total......	94.6	95.5	94.2	94.8

It will be noted that the average service hours for these boilers were 8330 hr., or 94.8 per cent.

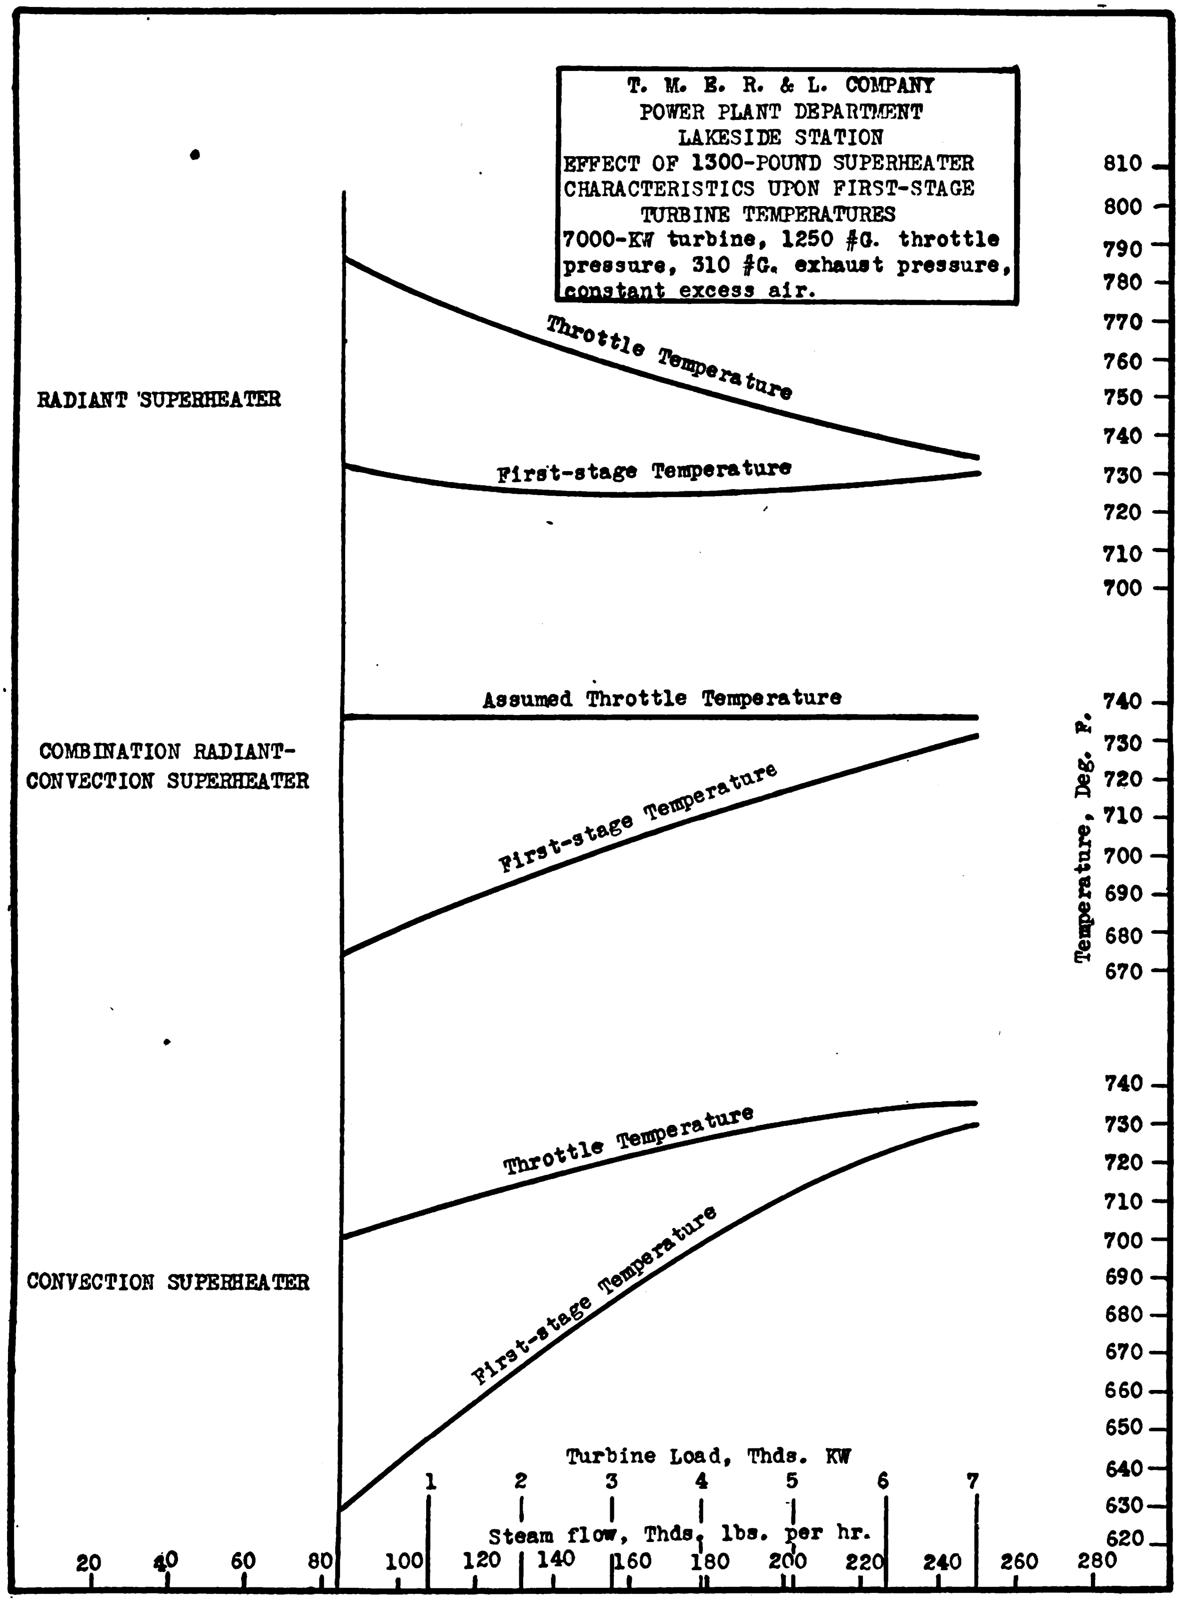

FIG. 18—EFFECT OF 1300 LB. SUPERHEATER CHARACTERISTICS ON FIRST STAGE TURBINE TEMPERATURES, THE MILWAUKEE ELECTRIC RAILWAY & LIGHT CO.

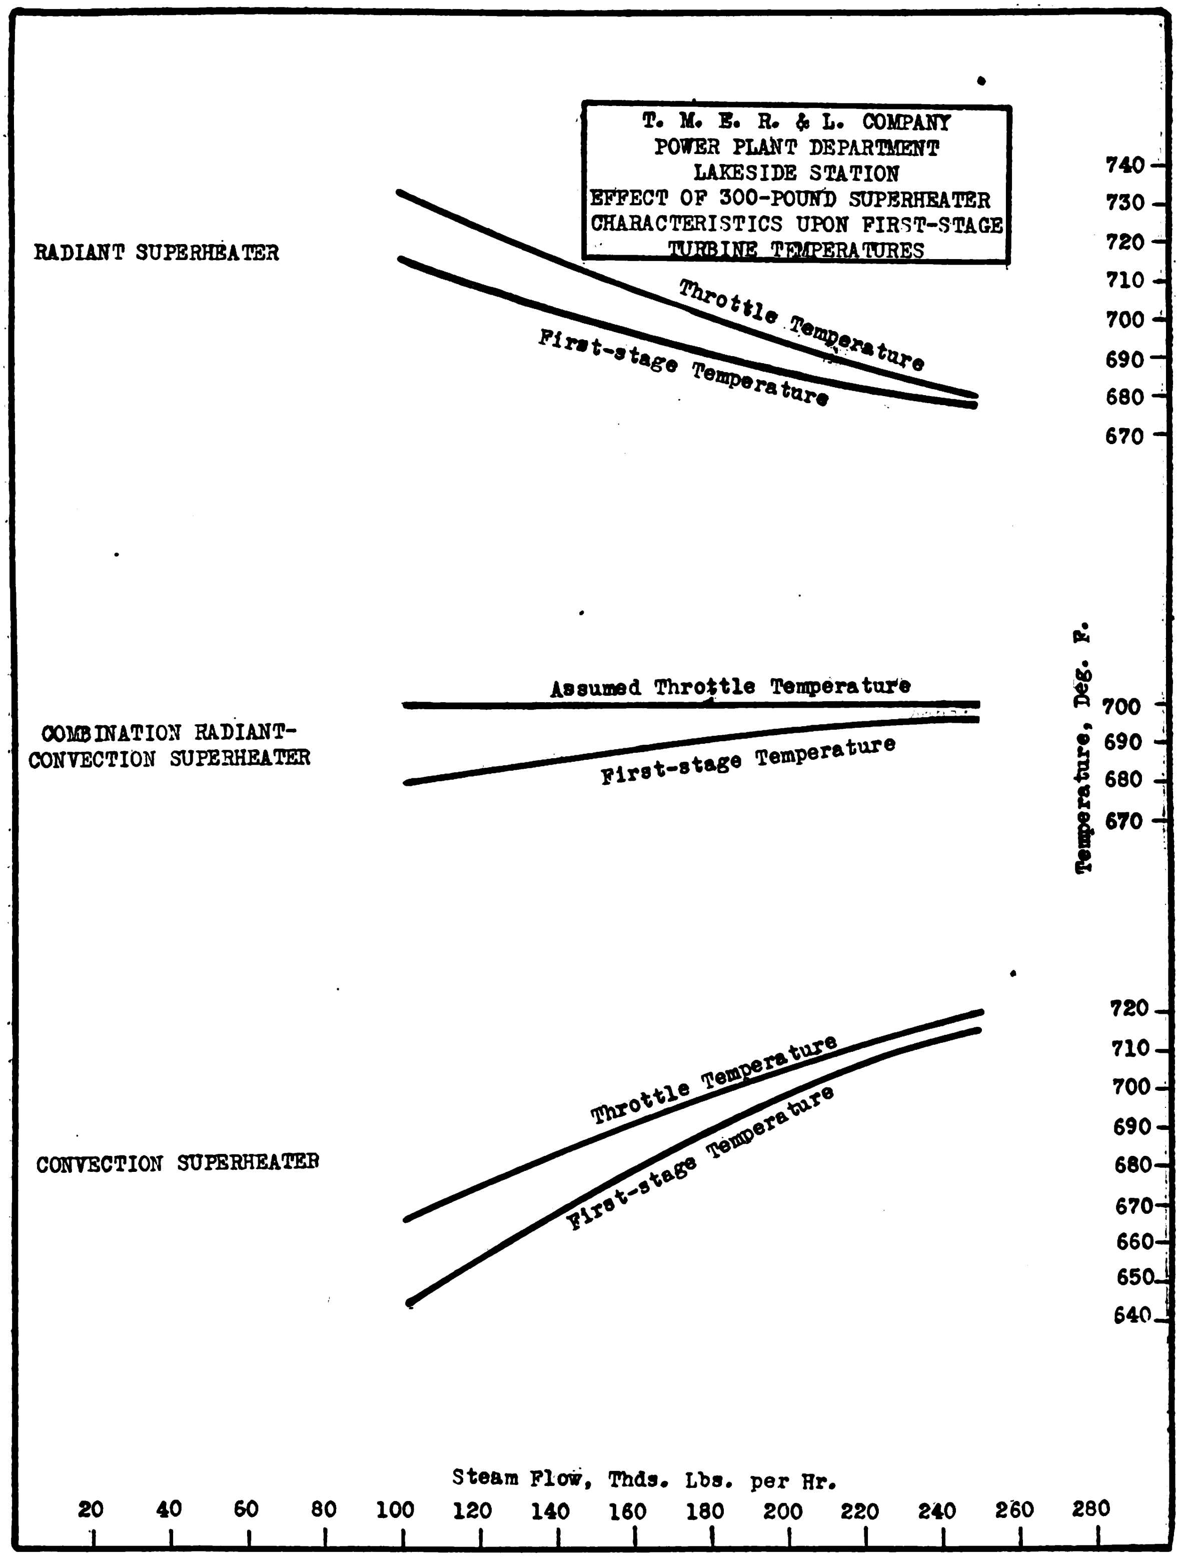

FIG. 19—EFFECT OF 300 LB. SUPERHEATER CHARACTERISTICS ON FIRST STAGE TURBINE TEMPERATURES, THE MILWAUKEE ELECTRIC RAILWAY & LIGHT CO.

Owing to the increased cost of operating the low-pressure boilers and turbines, every effort is made to use only high-pressure equipment. These boilers give varying superheats so that the boiler schedule is arranged to bank those boilers which give the lowest superheat at low ratings. Three boilers are run after 10 P. M. at about 3.3 k-B.t.u. per sq. ft. rating, the fourth boiler being banked.

Every Saturday night one unit is let down as soon as the other three can carry the load, usually about 10:30 P. M. At midnight, the induced draft fan is started and the boiler cools until 7:30 A. M., when the bricklayers get in to repair the furnace lining. The boiler is generally quite hot at this time, but it has been possible to do most of the work under these conditions.

This work is finished by noon, and a crew of slaggers gets in to clean the tubes in the first pass and superheater. This cleaning requires from 4 to 8 hr., depending on the kind of coal burned during the preceding weeks. As a usual thing the unit is ready to be fired up by 5 P. M. Sunday. However, if the coal has been particularly high in ash, causing severe slagging, or if soot conditions require extra cleaning of the superheater, the boiler may be kept off the line and put on Monday morning.

While the above-mentioned gangs are at work inside the boiler the mechanics and steam-fitters go over the various portions of the boiler and stoker, including fans.

The unit generally has been let out for about 18 to 20 hr. once a month for general cleaning and inspection. Once a year each unit is let out for 3 or 4 days for complete overhaul. There is nothing spectacular in this proceeding except that the crews are well organized, every man being assigned to a definite job, and every minute is made to count. In this way the boilers are kept out of service a minimum number of hours throughout the year.

During the summer months this work has been a little hard on the bricklayers who have to get into the boiler early in the morning; in the future it may be possible to operate in such a way that the boiler will always be left off until Monday morning, giving it a chance to cool a little longer after it has been shut down, before starting work.

STATEMENT BY THE NEW YORK STEAM CORPORATION, NEW YORK, N. Y.

Kip's Bay Station

The design of the Kip's Bay Station of the New York Steam Corporation was discussed in a statement appearing in the August, 1927, Report of the Subcommittee on Pulverized Fuel. This report may be referred to for details of design not appearing in this statement.

On Dec. 23, 1926, the first boiler at Kip's Bay Station was put into service, and boilers 2 and 3 were put into service within six months thereafter, although building construction, equipment installation and minor operating installations were still in progress. The station was shut down for the summer of 1927 in order that construction could be completed without interference from operation. Thus, the first period which could be depended upon to bring out any features of design and construction as related to capacity and continuity of service, was the winter of 1927-1928.

Boiler No. 4 was put into service on Dec. 2, 1927. In any statement of the operating experience at Kip's Bay Station, the experiences were common to four boilers unless specific reference is made to the contrary.

Three difficulties developed during the winter 1927-1928 which, until recently, have delayed the realization of some of the guarantees and expectations. These were:

1. Feed water treatment.
2. Moisture in steam.
3. Changes in coal characteristics, resulting in the slagging of the boiler tubes.

The plants of the New York Steam Corporation operate with no returns other than the steam from the plant auxiliaries. This feature of operation is not met with in other utilities and the importance of feed water treatment under these conditions of operation can be readily understood. During the winter season approximately seven million pounds of raw water are fed each day to each boiler at Kip's Bay, and although this water is drawn from the drinking water supply of New York City, it contains sufficient dissolved material to endanger the heating surfaces within ten days of operation at the existing rates. The protection of the heating surfaces by turbining would be costly, inasmuch as that part of the plant investment represented by boilers would have to be increased about 20 per cent for sufficient spare capacity to permit cleaning. The chemical method of preventing scale deposit is used and has been successful to a remarkable degree, but before the boilers were operated at high capacities for long periods, it was necessary to insure that the treatment was keeping the surfaces clean. The frequent inspections which were made and the earlier lack of assurance prevented the attainment of peak capacities and high percentages of active hours. All of the details and refinements of the treating system have not been worked out, but the boilers have been cleaned internally only two or three times within the last 16 months, and this only to insure against deposits on surfaces not readily inspected. No water wall tubes have been lost in this period, and such few boiler tube failures as have occurred have been caused by soot blower impingement and similar causes not traceable to deposits on the heating surfaces.

The economizer surfaces have required the greatest amount of cleaning. The cause of the formation of the deposit on these surfaces is understood, and it is expected that a minor change now being made in the treating system will completely eliminate this condition. The deposit has a major effect on water pressure loss which limits the peak attainable.

The chemical conditions in the boiler, the boiler design, and the rate of operating the units have all combined to produce an excessive amount of moisture in the steam. After an extensive investigation, a solution to the problem has been found which has eliminated the moisture problem in one boiler and which is being adapted to the other boilers as rapidly as operating conditions permit. The increase of moisture with rating naturally restricted capacity under normal conditions but did not constitute an absolute limitation.

It was found that the amount of moisture in the steam increased rapidly with increases in rating. With some types of separating equipment, there was a critical point on the rating curve above which the steam was very wet and below which the steam was commercially dry. The equipment now installed in one boiler, and which is being adapted to the other three, gives steam with less than ½ of 1 per cent moisture at an average rate of evaporation of 21.5 lb. per sq. ft. of boiler and furnace surface. The problem of moisture and the investigations carried out by the New York Steam Corporation will be discussed in detail in a paper to be presented before the A. S. M. E.

Variations in the composition of the ash in the coals used have caused serious curtailment of capacity at infrequent intervals because of the deposit of ash on the tubes at the entrance to the boiler and, until the cause was found, made it inadvisable to force the boilers to their greatest capacity. The coal used is a mixture from a number of mines among which there are some with a very low ash fusion temperature and with comparatively large quantities of pyritic sulphur in the ash. There was apparently no other variable than the coal to which the infrequent trouble with slag could be attributed, and it was found eventually that, although approximately constant proportions of the total coal used came from each mine, the shipments were separate and were not mixed at the piers in the same proportions in each barge. Therefore, a single barge might contain a comparatively high proportion of the harmful ingredients, and although the analyses were carefully made, sampling errors might cover up the troublesome features. After the proportioning of barge loadings had been stressed, no further trouble arose due to stoppage of the gas passage by slag. The units were designed to burn coal with an ash fusion temperature of 2200 deg. fahr. at a liberation rate of approximately 22,000 B.t.u. per cu. ft. and have burned this coal at liberation rates of 30,000 B.t.u. per cu. ft. for sustained peaks without trouble.

Fluctuating water levels have not given trouble. The reasons for this are probably two: First, that the multi-drum boiler has a large internal volume which can diminish the effect of changes in fluid volume, and second, that instantaneous load fluctuations are very rare. In addition, the effect of the economizer on these units is to decrease the condensing effect of large quantities of comparatively cold feed water which otherwise would enter the boiler directly from the open feed water heater.

Continuity of operation has been excellent in the last few months and no instance of enforced boiler outage is recalled for the period from Nov. 1, 1928, to the date of the preparation of this statement (Jan. 16, 1929). During this period the total outage of boilers was less than 14 per cent of the time and was made up principally of internal inspections, moisture experiments and ash cleaning. The figures are summarized in the following table:

ANALYSIS OF PRODUCTION

	Period			
	Nov. 1-30	Dec. 1-31	Jan. 1-16	Total
Total steam gen., M-lb.	679,738	798,048	760,348	1,938,134
Peak load, M-lb.......	1,467	1,466	1,513	1,513
Load factor, %........	64.3	73.2	79.2	69.3
Average rate per productive boiler hr., M-lb.	283	316	326	306
ANALYSIS OF SERVICE HOURS				
On the line, %........	83.4	84.7	91.8	86.2
Off for inspection and cleaning, %	2.0	7.0	4.1	4.4
Off for moisture experiment, %	5.8	5.8	0.0	4.5
Off for slag and ash removal, %	6.4	1.5	2.1	3.5
Off for minor repairs, %	2.2	0.9	1.1	1.4

In reference to the above table, it is interesting to note that the original guarantees covered a steam production of 325,000 lb. per hr. at maximum and, although some changes have been made to the boilers, the furnaces are exactly as installed and peak loads 15 to 20 per cent in excess of guarantees have been carried. On Jan. 16, 1929, the last day included in this summary, the plant generation averaged 1,501,000 lb. per hr. for 11 consecutive hours on 4 boilers.

STATEMENT BY THE PACIFIC GAS & ELECTRIC COMPANY, 245 MARKET ST., SAN FRANCISCO, CAL.

Large Boilers at Station "C," Oakland

The installation at Station "C," Oakland, consists of two oil-fired boiler units for operation at 450 lb. gage drum pressure, one of which is shown in Fig. 20. Each unit consists of boiler, water walls, superheater and air heater. Each unit was designed for a maximum output of 425,000 lb. of steam per hr., 730 deg. fahr., feed water at 365 deg. fahr., temperature of air to furnace 498 deg. fahr. and temperature of gases leaving air heater 353 deg. fahr.

The boilers are B. & W. cross drum, each with a heating surface of 35,453 sq. ft. The drums are 60 in. diameter and the tubes are 4 in., No. 6 gage (0.203 in.), 24 ft. long, arranged 51 wide and 24 high. Each drum is provided with a separating baffle to reduce moisture in the steam to the superheaters. The boilers are steel cased.

The furnaces are water cooled with Bailey walls in side and rear walls and front wall above burner wind box. The total water wall surface for each boiler is 1674 sq. ft. The furnaces are 25 ft. high at the uptake end; heat liberated at maximum output is at the rate of 37,000 B.t.u. per cu. ft. per hr. The external surface of the water walls is finished with hard surface insulating plaster.

The superheaters are B. & W., three-pass, interdeck, each with 6553 sq. ft. heating surface. The tubes are 2-in., No. 10 gage (0.134 in.).

Each air heater is of the tubular type, having a total heating surface of 51,323 sq. ft. The tubes are 2½ in. diameter, No. 11 gage (0.120 in.), 36 ft. long, arranged 32 deep by 68 wide.

There is one forced and one induced draft fan per boiler unit. These are both Sturtevant vane control type. The forced draft fans each have a capacity of 550,000 lb. of air per hr. against a pressure of 15 in. of water. The capacity of each induced draft fan is 600,000 lb. of gases per hr. at 7½-in. draft.

Each fan is driven by two 2300-volt, squirrel cage motors, one high speed and one low speed, either one of which may be started by throwing directly across the line. All of the higher speed motors are 400 h.p.; the lower speed motors are 150 and 210 h.p. for the forced and induced draft fans respectively.

Firing is controlled by the Bailey Control System, arranged for either push button or automatic control. Automatic devices have been installed to shut down the fans in the event of excessive furnace draft; also, to shut off fuel supply in case the induced draft fan stops.

The water columns are approximately 50 ft. above the firing floor and a periscope was installed for showing the water level at the firing floor. This has proved very satisfactory, but in addition, distant water level gages were provided.

The water level in the drums is automatically maintained by S-C controllers. A differential pressure regulator is cut in ahead of each controller and a constant pressure of approximately 550 lb. is maintained at the feed water header to each boiler.

A power control valve was installed on each superheater outlet principally in order to permit of higher operating pressure at the superheater outlet.

The single stack for the two units is 150 ft. above the firing floor and is of welded steel, lined with Gunite.

These units went into service about the middle of October, 1928, and have been in continuous service since. Experience, so far, indicates that very large boiler units, equipped with water walls, and with proper feed water are going to prove very reliable with low maintenance and operating costs. It is believed that they will be as reliable as other equipment in the plant. Especial mention should be made as to the flexibility and ease of control of these large units as compared with a larger number of small units. Brief experience indicates that the anticipated advantages of very large boiler units will be realized in every respect.

1200-Lb. Installation at Station "A," San Francisco

In the new 1200-lb. installation at Station "A" it is expected that the operating pressures and temperatures will be as follows: Boilers, 1350 lb., 750 deg. fahr.; turbines, high pressure, 1200 lb., 750 deg. fahr.; low pressure, 400 lb., 750 deg. fahr.; feed water 430 deg. fahr.; air temperature to furnaces approximately 450 deg. fahr.; final gas temperature approximately 325 deg. fahr.

Some of the boilers will have reheaters and the remainder will be of standard design. The standard boiler unit will consist of boiler, water walls, superheater, economizer and air heater. The boiler will be 8 high and 62 wide, with 20-ft. tubes, and the unit will have a maximum output of 400,000 lb. per hr.

The reheat units will be exactly like the standard unit with the addition of a 400-lb. reheater with a capacity of 440,000 lb. per hr. Live steam reheaters will be used in connection with the convection type gas reheaters to maintain the temperature at approximately 750 deg. fahr. at all loads and also to give some reheat if the reheat boilers are out of service.

The boiler feed pumps will probably be of the so-called "interrupted" type, driven by steam turbines.

The station will contain two compound units rated at 50,000 kw. (55-60,000 kw. maximum).

STATEMENT BY THE PENNSYLVANIA POWER & LIGHT COMPANY, ALLENTOWN, PA.

Boiler Outage, Water-Cooled, Hopper-Bottom Boilers

At the Pine Grove Steam-Electric Station one of the boilers has been equipped with a water-cooled hopper bottom only since May, 1928, and so the proportions given below for that boiler are for only a part of a year:

Boiler Station No.	8	9
Period reported on	June-Dec. inc., 1928	Year, 1928
Available hr., %	82.5	81.2
Repair hr., %	17.5	18.8
Operating hr.	3,725	5,843
Available hr.	4,238	7,129

The data given in the above tabulation are not strictly typical, even for these boilers. Due to their newness, considerable experimenting has been done and the outage caused by changes in furnaces, superheaters and soot blowers included, cannot be classed as outage for maintenance.

To date outages have been due chiefly to furnace maintenance, caused by failure of the arches on top of the Dutch ovens. Failure of the upper part of the back wall above the water-cooling surface also accounted for numerous outages. Soot blower misalignment, causing cutting of the tubes, was also responsible. Difficulties in obtaining the proper steam temperature from the superheaters caused the boilers to be taken out of service a number of times. In all, each of these boilers has averaged about one outage a month.

It should be possible this coming year to predict nearly all maintenance required, and schedule the outages accordingly. It is hardly likely, though, that it will be possible to keep these boilers available for service 95 per cent of the time which, as has been stated, is the goal for which to strive. However, as familiarity is gained with their peculiar characteristics, it may become possible to approach that very desirable goal.

Boiler Baffling, Shamokin Station

The results with cross baffling and parallel baffling are widely different and could not be called comparable. In addition to changing the baffling of two boilers, their furnaces have been changed to an entirely different type to utilize No. 4 buckwheat and culm, where previously No. 3 buckwheat was burned. The stokers also have been changed, and although of the same type are of later design. In all, combustion conditions have been improved, permitting operation with considerably less excess air due, largely, to reducing stratification of gases in the furnace throat.

To what extent flue gas temperature has been improved by the changed baffling is hard to say. Draft losses appear to be greatly decreased. Specific data for comparison are not available as these units have only been in service about two months and tests are under way at this time.

STIRLING BOILERS (5890 Sq. Ft.)

STATEMENT BY THE PHILADELPHIA ELECTRIC COMPANY, PHILADELPHIA, PA.

Soot Blower Tests

At the Chester Station a series of tests were run to determine the effect of economizer soot blowing on stack losses and also on scale or soot formation. To determine the

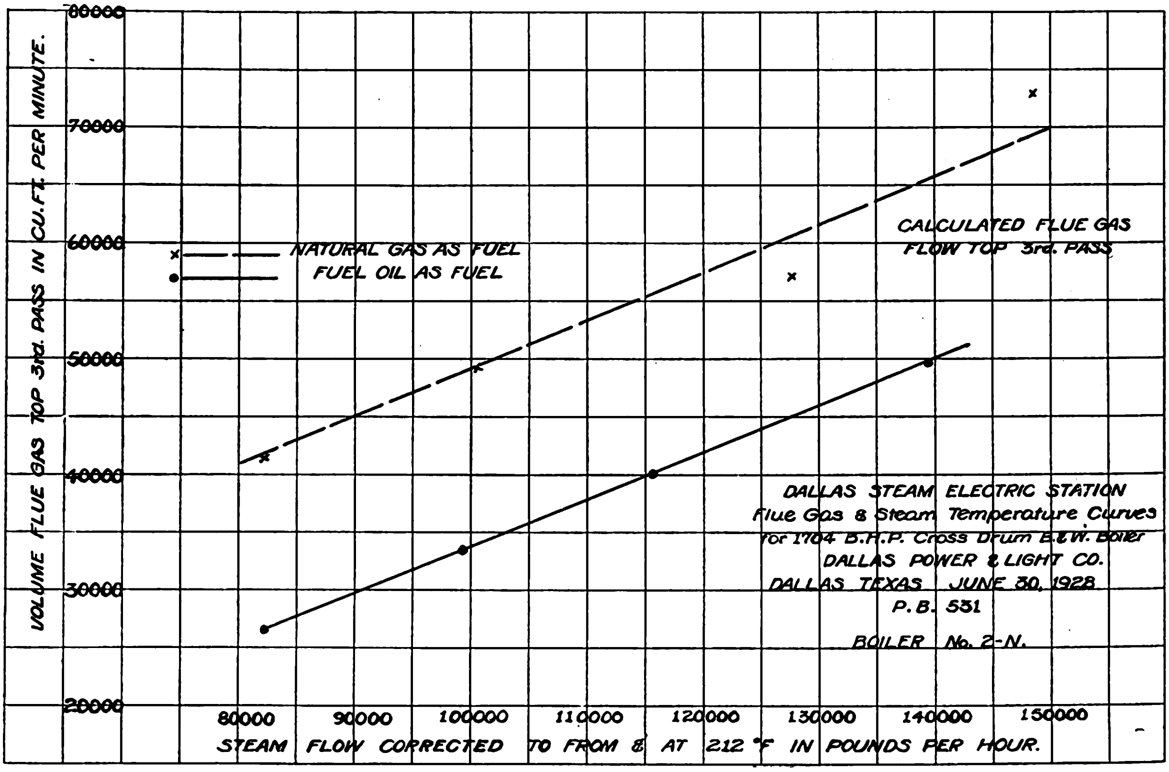

FIG. 21—FLUE GAS FLOW, 17,041 SQ. FT. BOILER, DALLAS POWER & LIGHT CO.

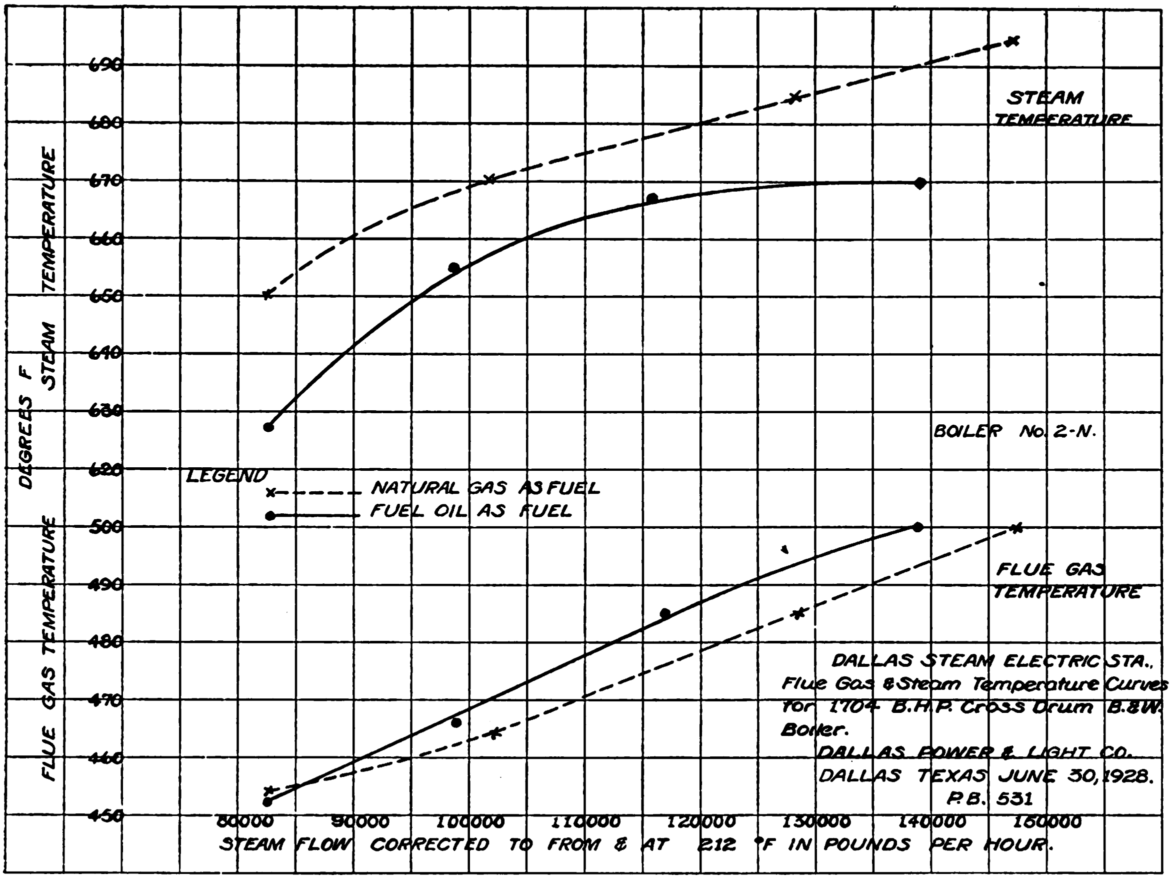

FIG. 22—FLUE GAS AND STEAM TEMPERATURES, 17,041 SQ. FT. BOILER, DALLAS POWER & LIGHT CO.

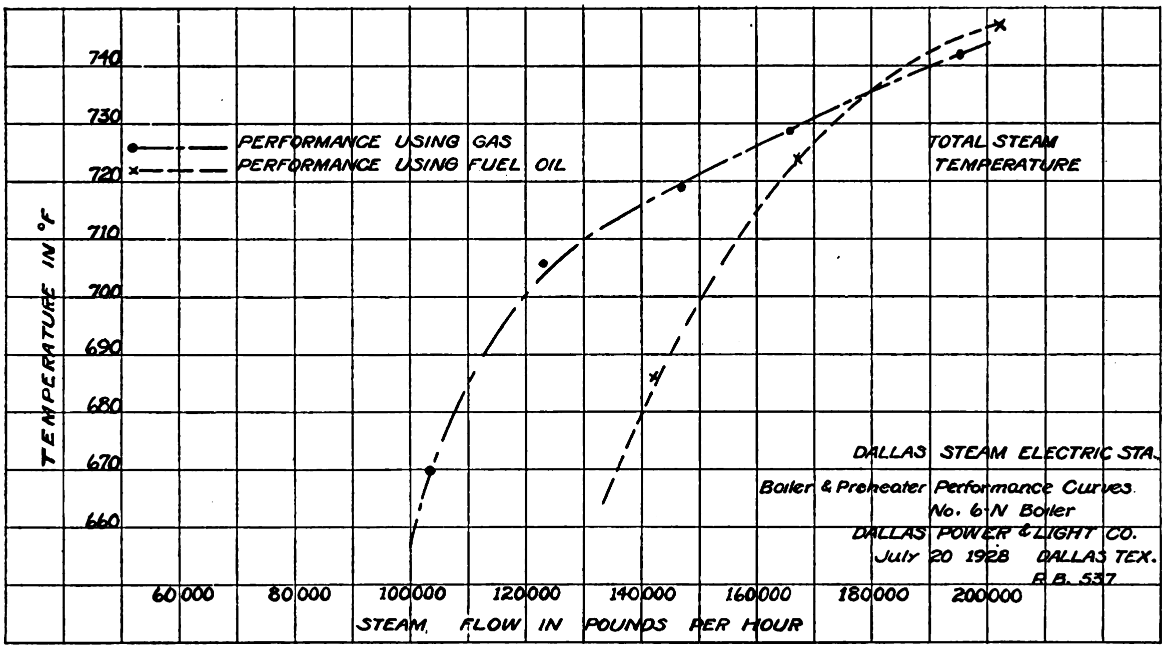

FIG. 23—STEAM TEMPERATURE, 14,220 SQ. FT. BOILER, DALLAS POWER & LIGHT CO.

effect on stack losses, tests were run on four boilers, two with soot blowers and two without. The tests were taken over a period of six months, during which readings were recorded on boiler exit gas temperature, economizer exit gas temperature, boiler feed temperature, steam temperature, air flow and CO_2. The data did not indicate any perceptible difference between the stack losses on the soot blown boilers and on those that were not blown.

To determine the effect of soot blowing on soot or scale formation on the economizer, two boilers were cleaned equally well. On one of these the soot was blown from the economizer, and the other was merely given the usual brushing during the regular inspection period. At the end of three months it was found that the operation of the economizer soot blowers made no appreciable difference in scale or soot formation.

Tests were also run at Delaware Station similar to those at Chester to determine the effect of economizer soot blowing on stack losses, and similar results were obtained; that is, it was found that economizer soot blowing caused no appreciable decrease in flue gas exit temperatures.

The test at Richmond Station was made to determine, in this case, the effect of superheater soot blowing on steam temperature. The steam temperatures on two boilers were recorded for several months, one boiler having a soot-blown superheater and the other not provided with a soot blower. The steam temperatures in the two cases were found to have approximately the same average, showing that there was no appreciable effect on the superheat due to soot blowing.

As a result of the investigations referred to above, soot blowers are not being used in connection with either the boilers, the superheaters or the economizers in the Chester, Delaware and Richmond Stations of the Philadelphia Electric Company.

Comparative Results with Oil and Natural Gas as Fuel

There is some little difference in results obtained from superheaters when change is made from natural gas to oil, or vice versa. There is also some difference of opinion as to whether the superheat is greater with gas or oil firing. The probable reason for this apparent discrepancy is that the amount of superheat changes with the rating at which the boiler is operated, and the curves showing superheat with the two kinds of fuels burned where results are carefully taken over a wide range show that at some ratings superheat with gas firing is higher and at other ratings lower than with oil firing. It is, therefore, necessary to run a series of very careful tests over a wide range of ratings in order to obtain reliable data as to the superheat to be expected from any particular set of boilers.

The amount of superheat is dependent upon the amount of excess air, the location of superheating surface, the presence or lack of water wall surface and the rating at which the boiler is being operated. The volume of the products of combustion from natural gas is greater than from fuel oil for any given rating when the percentage of excess air is kept the same.

Fig. 21, 22 and 23 show curves obtained from a series of tests conducted by the Dallas Power & Light Company on two types of boilers with oil and natural gas burned under each of them. Extreme care was taken during these tests to maintain stable conditions, and the boilers were operated as nearly as possible under similar conditions. The excess air was approximately 15 per cent with each fuel, and the feed water temperatures were kept as closely as possible to the same values. The gas was burned with Forney gas burners, manufactured by the Forney Combustion & Engineering Company, Dallas, Texas, and the oil with B. & W. San Diego type oil burners. The description of the two boilers tested is as follows:

Boiler No. 2N is a B. & W. cross drum water tube boiler, 22 tubes high, having 17,041 sq. ft. of water heating surface, baffled for 3 passes. There is installed a 2361 sq. ft. B. & W. interdeck superheater located above the 6th row of tubes. The setting is of the ventilated fire brick type.

Boiler No. 6N is a B. & W. cross drum water tube boiler having 14,220 sq. ft. of water heating surface with water walls having a surface of 609 sq. ft. The 3210 sq. ft. superheater is of the interdeck B. & W. type located above the 9th row of tubes.

Table V gives the data obtained from tests of these boilers.

STATEMENT BY THE SOUTHERN CALIFORNIA EDISON COMPANY, LOS ANGELES, CAL.

Operation of Three 34,164 Sq. Ft. Cross Drum Boilers

Early in 1928 three 34,164 sq. ft. B. & W. cross drum boilers were installed with the first unit in the new Long Beach Steam Plant No. 3. These boilers have been in operation about 7 months, supplying steam for a 94,000 kw. turbine-generator unit. The unit has carried gross loads of 110,000 kw., the steam for which was generated by the three boilers. At the present time no spare boiler is provided.

The boilers (Fig. 24) are 51 tubes wide and 23 tubes high. The tubes are 4 in. diameter, No. 6 gage (0.203 in.); the drums are 60 in. diameter. The furnaces are directly below the boilers, and are completely inclosed by water-cooled walls. The burners are combination gas and oil, manufactured by the Peabody Engineering Corporation. Twenty burners are installed in each furnace. The furnace volume is 19,800 cu. ft., about 14,000 cu. ft. of which is above the lower burners. The lower portion of the furnace forms a hopper for possible future pulverized coal burning. The water-cooled walls are of the Bailey type, manufactured by the Fuller Lehigh Company, constructed of refractory-faced cast iron blocks, cemented and bolted to the water-cooling tubes. Each B. & W. air heater contains 2176 tubes, 2½ in. diameter and 36 ft. long. The total external heating surface is 51,232 sq. ft.

The superheaters are convection type, three-pass, quadruple deck and located immediately above the lower deck of boiler tubes in the first pass. The tubes in the first two passes of the superheater are of steel. The tubes in the third pass are of seamless Enduro S-188, a chrome nickel steel alloy. The contract heating surface of each superheater was 6553 sq. ft., of which only 5823 sq. ft. was initially installed. It is intended that the full amount of heating surface shall be installed as soon as the boilers can be released for this purpose.

Each boiler is served by two forced draft fans, each driven by a 140 h.p. type BTS variable speed motor, and one induced draft fan, driven by a 300 h.p. type BTS variable speed motor. The fans are manufactured by the Green Fuel Economizer Company and the motors by the General Electric Company. The capacity of each forced draft fan is 53,000 cu. ft. per minute, and the capacity of the induced draft fan is 180,000 cu. ft. per minute. The maximum forced draft air pressure is 15 in. of water, and the maximum induced draft fan pressure is 7 in. of water. To insure tightness at these pressures the flues and forced draft air ducts are all welded.

The maximum allowable boiler operating pressure is 460 lb. All joints in the feed water piping on the boiler side of the valves nearest the boiler are Sargol, welded for tightness, as are all steam joints, including the joint between the safety valves and the boiler drum. All joints in the water-cooled furnace walls, except where tubes are rolled into headers and drums, are welded. By this precaution of welding all joints for tightness, the danger of being forced to shut down one of these large boilers because of blown gaskets is minimized.

Complete automatic combustion control manufactured by the Bailey Meter Company is used. In addition to the Bailey boiler meter and multipoint draft gage, each boiler gage board is equipped with a Foxboro water level recorder, a flow meter for feed water, a flow meter for fuel oil, a Westcott gas flow meter for fuel gas, a Mono CO_2 and CO recorder, and a Leeds & Northrup six-point temperature recorder. The water and oil flow meters are Venturi type, manufactured by Builders Iron Foundry. Flat gage glasses are used in the water column gages, located 49 ft. above the floor.

The summary of operation results, boilers 49, 50 and 51 for the period from June 20, 1928, to Jan. 15, 1929, in Table VI, presents a summary of operation data from the date of placing these boilers in service to the date of this report (Jan. 16, 1929).

The weighted average evaporation per boiler for the period reported was 293,000 lb. per hr., or 262 per cent of builder's rating. The maximum evaporation for one hour was 433,000 lb. of steam, or 386 per cent of builder's rating. The longest continuous operation period for one boiler was 2601 hr.

No unusual operating conditions developed during the seven months that these boilers have been in practically continuous service. Sudden changes in load cause considerable changes in water level in the boiler drum, but not great enough to cause concern. The apparent reliability of the water level recorders has contributed to this assurance. Fluctuations in output from 200,000 to 325,000 lb. of steam per hr., cause 4 in. fluctuation in water level. An accidental closure of the main steam lead from boiler No. 49 on Oct. 20, 1928, with a sudden drop in output from 310,000 lb. of steam per hr. to zero, dropped the water level to 1.5 in., with a momentary swing up to 14.5 in. when the valve was opened. Of course, the safety valves were blowing during this period, although the fuel flow, which was gas, was immediately cut to zero.

Tested moisture contents in the saturated steam line were found as follows:

Output, lb./hr.	100,000	200,000	300,000
Water in glass, in.	Moisture, per cent		
5	0.10	0.12	0.13
10	0.13	0.16	0.18
15	0.16	0.21	0.24
20	0.20	0.25	0.30
Highest observed value with 20 in. in glass, per cent	0.20	0.29	0.36

The realized steam temperature has been lower than anticipated. It is hoped, however, that the manufacturer's guarantee of 750 deg. fahr. total temperature at a steam flow of 350,000 lb. per hr., or 322 per cent rating (10.8 k-B.t.u. per sq. ft. per hr.) will be realized when all of the superheater surface has been installed. The pressure drops through the superheater have conformed closely to the manufacturer's predictions.

Burning gas with about 11.5 per cent CO_2 and operating the boiler at about 320 per cent (10.7 k-B.t.u. per sq. ft. per hr.) rating, the following temperatures are observed:

Gases leaving boiler, °F	510
Gases leaving air heater, °F	295
Air entering air heater, °F	100
Air leaving air heater, °F	385

Under these conditions steam is delivered to the turbine throttle at 400 lb. gage pressure, 709 deg. fahr. total temperature, with feed water to the boiler at 388 deg. fahr. The feed water is heated by steam extracted from four stages of the turbine.

Statement by the Texas Electric Service Company, Dallas, Texas

Comparative Results with Oil and Natural Gas as Fuel, Wichita Falls Steam Electric Station

A series of tests were recently run on two Edge Moor 5870 sq. ft. boilers for the purpose of determining the effect on the temperature rise and pressure drop across the convection and radiant superheaters at various ratings when burning either gas or oil. Fig. 25 shows a vertical section of these boilers, the general arrangement being the same for both of them. In No. 6 boiler short U bends have been substituted for the original convection elements, and the radiant superheater is of two pass design. In No. 7 boiler the original Foster convection superheater has been retained, and the radiant superheater is single pass. Fig. 26 shows relative temperature rises and pressure drops through superheaters on boiler No. 6 when burning oil and gas. Fig. 27 gives similar data for No. 7 boiler. Table VII summarizes the pressures, temperatures and combustion conditions for each test.

Tests were run on each boiler at four different ratings. Excess air was kept as low as possible during all tests. With the low rating on oil only the two center burners could be used, and considerable excess air passed through the two outside burners. The curves, Fig. 26 and 27, show the superheat obtained divided between rise in convection and radiant superheaters.

Superheater Test

Boiler No. 6 is an Edge Moor 3 drum, 2 pass boiler, 250 lb. pressure, 5870 sq. ft. There are 263 tubes, 4 in. by 20 ft. arranged 18 tubes wide by 15 tubes high.

The Foster Wheeler convection superheater is located at the top of the first pass and consists of short U bends to replace the original convection superheater elements. There are 19 U bends with an approximate area of 48 sq. ft. each.

The Foster Wheeler radiant superheater, 2 pass type, is located at the furnace rear wall and consists of 20 elements, 4 in. by 111 in., or an area of 62 sq. ft. A curtain wall of brick is 27 in. high above the bottom of the elements, leaving 47 sq. ft. of superheater exposed.

Furnace dimensions are 10 ft. 5 in. wide by 17 ft. deep, with an average height of 12 ft., making the furnace volume 2400 cu. ft.

There are four Duquesne low-pressure gas burners located in a Dutch oven at the front of the furnace. For emergency oil burning a Leahy steam atomizing oil burner is inserted in center of each Duquesne gas burner.

Boiler No. 7 is the same as boiler No. 6. The Foster Wheeler convection superheater with cast iron external surface is located at the top of the first pass. There are 22 U shaped elements of 2 in. tube, 20 ft. long overall.

The Foster Wheeler radiant superheater, single pass type, located at the rear wall of the furnace, consists of 12 elements, 4 in. by 91 in., or an area of 30 sq. ft. A curtain wall of brick 15 in. high above the bottom of the elements leaves 25 sq. ft. of superheater exposed. Furnace and burners are the same as in boiler No. 6.

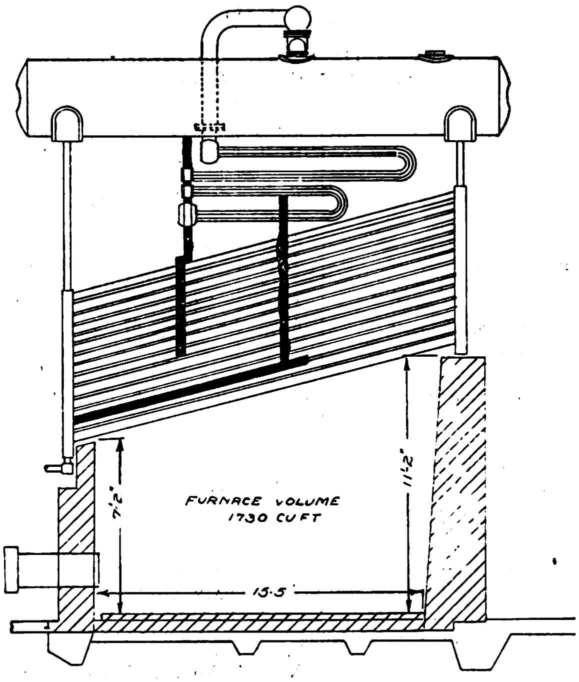

FIG. 28—6000 SQ. FT. BOILER, WACO STATION, TEXAS POWER & LIGHT CO.

STATEMENT BY THE TEXAS POWER & LIGHT COMPANY, DALLAS, TEXAS

Effect of Variation in CO_2 Content of Flue Gas on Superheat, Waco Steam Electric Station

In the 1923 Report of the Subcommittee on Boilers, Superheaters and Economizers, the effect of variation in CO_2 content of flue gas on superheat in a 6000 sq. ft. B. & W. boiler was reported. Recently a number of tests were run on a duplicate boiler arranged for gas firing for the purpose of determining the effect on superheat temperature when varying the CO_2 in the flue gas. Fig. 28 shows a section of this boiler as arranged at present. It is a 6000 sq. ft., 3 drum B. & W. boiler with 294 tubes, 14 tubes high by 21 tubes wide. The B. & W. superheater is a double loop convection type with 1277 sq. ft. of heating surface located at the top of the first pass. Fig. 29 shows the variation in superheat, flue gas temperature and draft loss with variation in CO_2 at different ratings.

For comparative purposes the superheat data given in the oil burning tests mentioned above have been included in Fig. 29. In comparing these results for oil firing, due consideration should be given to the change in furnace and baffle arrangement from that shown in Fig. 342, p. 252 of the 1923 Report.

Operation of Three 18,750 Sq. Ft. Cross Drum Boilers, Trinidad Station

Table VIII gives the history of boiler operation at Trinidad for 1928.

During the past year considerable outage has been due to soot blower maintenance and troubles, superheater troubles and special jobs. Because of the high cost of soot blower maintenance and the increased length of outage for soot blower inspection and repair, their use has been discontinued

Column B is outage during no-demand.

in favor of a hand lance, in view of the negligible improvement in efficiency obtained with soot blowers.

The table shows that on a basis of boiler outage for scheduled inspections, brickwork and turbining of tubes, the maximum possible unit operation factor ranged from 87.4 per cent for boiler No. 1 up to 89.2 per cent for boilers No. 3 and 4. For 1929 operations, a tentative schedule of two weeks' outage in each four months' period has been set which would give an availability factor of 88 per cent.

It is believed that the difficulties have been overcome which made frequent inspection and long outage necessary, and that it will be possible to increase the length of service between outages and decrease the length of outage below the two weeks allotted, but do not feel justified in predicting better than an average of 88 per cent at this time.

Boiler capacity at the Trinidad Station is such that three boilers will supply the maximum station load, and the only need of keeping a fourth boiler available is to insure against curtailment of load in case of unexpected boiler failure.

STATEMENT BY THE UNITED GAS IMPROVEMENT COMPANY, PHILADELPHIA, PA.

Deepwater Station

The Deepwater Station, which is now in the process of construction, will contain six 1400 lb. boilers, each of which will have 9000 sq. ft. of heating surface. Two will be erected with reheaters installed having 23,562 sq. ft. of surface. The steam temperature delivered by the superheaters will be 725 deg. fahr., and that delivered by the reheaters will be 750 deg. fahr. The four standard boilers will have 18,326 sq. ft. of economizer surface, and the reheat boilers 4765 sq. ft. of economizer surface. All boilers will be equipped with plate type preheaters containing 42,693 sq. ft. of surface, from which the outlet temperature is expected to be about 460 deg. fahr. at maximum rating.

The boilers will be fired with pulverized coal. Three boilers, having the bin system and Couch burners, will be equipped with bare tube water walls of 2540 sq. ft. heating surface, consisting of vertical tubes backed up with fire brick. The other three boilers, fired with the unit system and Fuller Lehigh cross tube burners, will contain 2755 sq. ft. of water walls of the same design. The furnace volume will be 19,080 cu. ft., and the maximum liberation 22,640 B.t.u. per cu. ft. The firing system for the three boilers on the bin system will be manufactured by the Combustion Engineering Corporation. The other boilers will be fired with the Fuller Lehigh unit system.

The maximum steaming capacity of the four standard boilers will be 331,000 lb. of steam per hr. each, and that of each reheat boiler will be 290,000 lb. per hr.

STATEMENT BY THE WEST PENN ELECTRIC COMPANY, 14 WOOD ST., PITTSBURGH, PA.

Cleaning of Economizers, Springdale Power Station

Being in doubt as to what method of cleaning to employ on the economizers, only one unit, No. 7, was equipped with soot blowers. An element was placed at one end, having nozzles its full length. In the opposite end two elements were installed, one to clean the tubes in the upper section, the other, those of the lower section. These elements were operated every 8 hr. Inspection of this unit when taken out of service for general cleaning showed the ash to be packed between the tubes and against the headers in such quantities that removal was necessary with hooks and scrapers.

A washer was then installed on No. 10 unit. Test results proved to be very satisfactory, and the remaining units were so equipped, with the exception of No. 7. Unit No. 7 was left as originally installed for comparison, due to the trouble which was being experienced at other stations from leakage at the tube roll.

From September, 1925, to March, 1926, each unit was given a daily washing of three minutes for each of the 8 elements, the boiler operating at approximately 200 per cent (6.7 k-B.t.u. per sq. ft. per hr.) rating.

Tests made at this time showed that weekly washings of one hour each with all elements washing were more efficient than the daily washings, and could be done during the time the boiler was banked to wash the superheater. The units were found much cleaner when taken out of service for general repairs, and that the time required for general cleaning of the boiler was reduced one day. The curve, reproduced in Fig. 30, shows the results obtained.

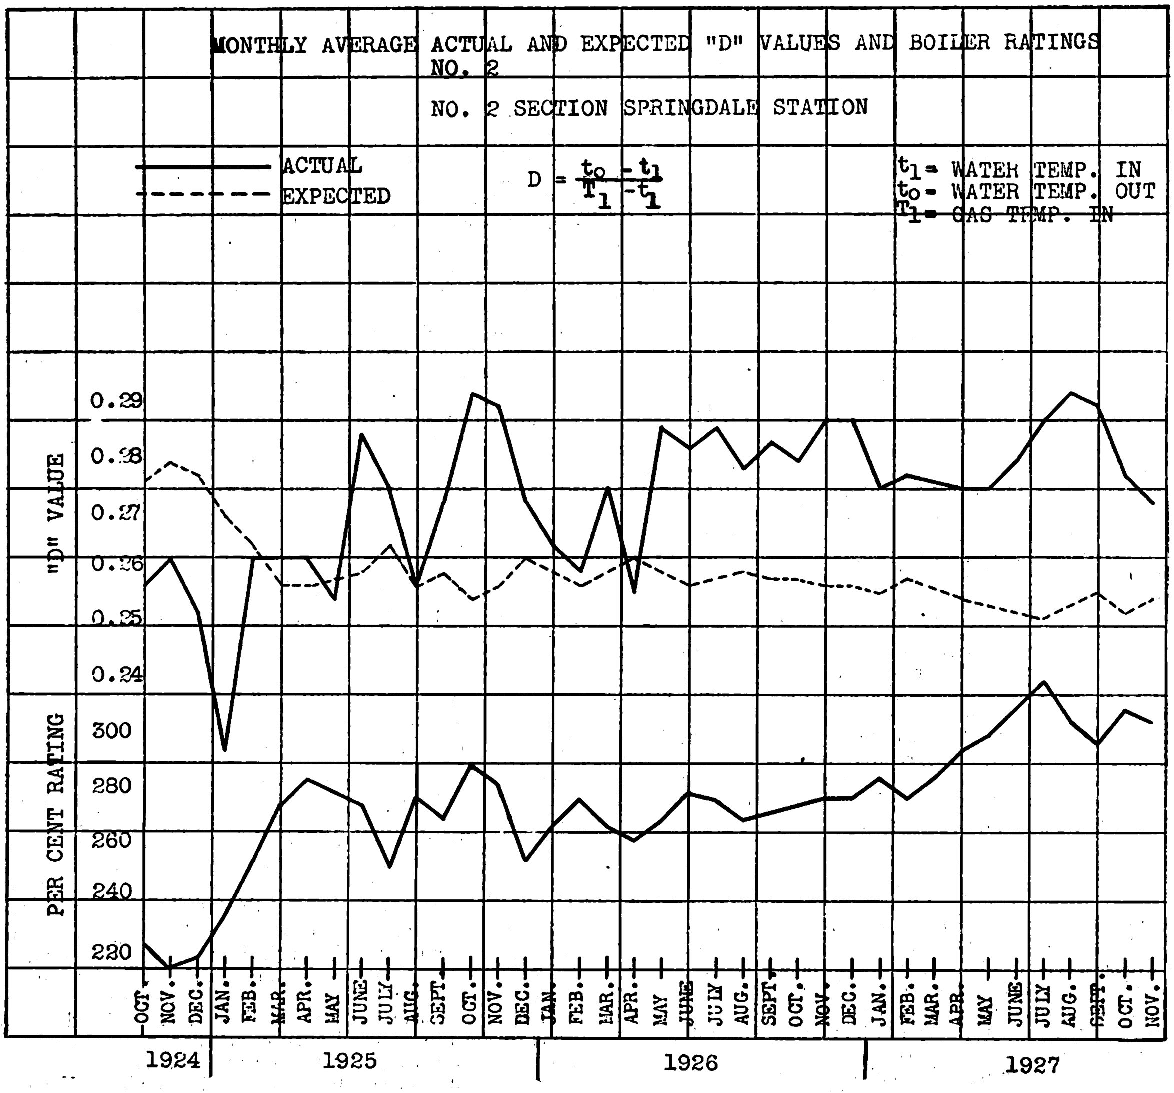

FIG. 30—EFFECT OF ECONOMIZER WASHING, THE WEST PENN ELECTRIC CO.

MANUFACTURERS' STATEMENTS

The Prime Movers Committee does not accept responsibility for any manufacturers' statements in this report.

BOILERS AND WATER WALLS

STATEMENT BY THE BABCOCK & WILCOX COMPANY, 85 LIBERTY ST., NEW YORK, N. Y.

1928 *Design of Stirling Boiler*

With developments in fuel burning equipment, increased furnace sizes and furnace wall protection methods, rates of B.t.u. release per ft. of furnace width became possible that were out of proportion to the amount of heating surface per foot of such width in the earlier designs of Stirling boilers.

With increased rates of combustion, draft losses through the boiler increased correspondingly, but such losses were not a serious factor as economizer, air heater or combination installations came more and more into common use. With lower exit temperatures and increased total draft requirements, natural draft stacks became impracticable, and the use of induced and forced draft fans became a necessity.

To meet these conditions the 1928 design of Stirling boiler was developed. The amount of boiler heating surface per ft. of furnace width was increased over earlier designs some 60 per cent. The increased amount of heating surface per ft. of furnace width, besides a baffle arrangement for making the gases hug the tubes more closely particularly in the second pass, tends toward increased efficiency.

The superheater location relative to the furnace and first baffle results in a flatter superheat curve than in the earlier classes. The new location makes the superheater, in effect, a combination convection and radiation superheater in that it "sees" the furnace through the tube lanes.

The arrangement of tubes relative to the various drums and the number and arrangement of steam and water circulators is such that the new design is able to operate with a higher degree of concentration without priming.

Slagging

The problem of slag screen design and arrangement of boiler tubes in the first pass is very difficult to crystallize in the form of certain definite recommendations because of the number of variable factors which tend to produce slagging. Different fuels and different methods of firing may be expected to cause varying degrees of difficulty, ranging from complete freedom from slag with natural gas to a maximum of slagging with pulverized coal, high in ash of low fusion point. The most trouble occurs with pulverized coal firing because of the higher percentage of ash in suspension. High ratings sustained for long periods and low excess air are other conditions which aggravate boiler tube slagging.

Since high furnace temperatures are necessary for best efficiency and since this aggravates slagging, the problem is one of reducing temperatures to the zone between the minimum temperature for complete combustion and the maximum temperature entering the boiler tubes which will not create troublesome slagging. Factors which must be taken into account are: design of slag screen, arrangement of boiler and superheater tubes, heat liberation in the furnace (particularly above the top of the burners), heat absorbed by radiation, burner performance, size and velocity of ash particles impinging on the tubes.

Close tube spacing in the lower rows makes it easier for formations to build out between tubes and close the gas passages. Close tube spacing results in higher gas velocity, so that a particle of ash does not remain in "sight" of cold tube surface as long as at lower velocity and hence does not have as much time to be relieved of heat by radiation. Certain types of boilers have small tubes grouped close together, the groups being situated relatively far apart. Calculations may show that the total area between tubes is sufficient for a moderate gas velocity, but the actual velocity may be much higher, due to ash and slag quickly filling up the narrow spaces between the tubes in the several nests. High velocity may carry molten slag particles some distance into the pass. A closely set arrangement of superheater tubes will form the final barrier which will intercept slag and ultimately close off the passage.

Some typical arrangements of slag screens with B. & W. boilers are shown in Fig. 31. A satisfactory slag screen has been developed for a Stirling boiler by bending every other front tube of the front bank in such manner that alternate tubes of this row are in a different plane crosswise of the setting, forward of their normal position.

B. & W. Cross Drum Steam Baffles

With cross drum B. & W. boilers operating at capacities up to 150,000 lb. of steam per hr., satisfactory steam quality is obtained with a vertical baffle plate placed somewhat back and away from the steam discharge tubes or circulators. With this construction, steam and water coming into the drum from the circulators are separated beneath the baffle, in the travel lengthwise of the drum under the baffle, and again in the partial lengthwise travel of the drum outside the baffle in the reverse direction.

As capacities are increased materially above this output, the high steam velocities prevent proper separation and actually result in picking up water from the surface. It has, therefore, been necessary to change this standard type of design. The fundamental change was the substitution of transverse flow for longitudinal flow of steam in the drum. The method of accomplishing this is shown in Fig. 32.

Over the steam circulators is installed a set of shutter baffles, the function of which is largely to dissipate the velocity of the incoming steam and water and to separate most of the water from the steam. Outside of the shutter baffles is a typical vertical baffle with an inclined top portion; above this inclined portion another inclined baffle plate forms a channelway for the steam flow. Above this, a box type dry-pan replaces the old round dry-pipe, giving considerably more headroom. This baffling is now standard for capacities in excess of 150,000 lb. per hr.

Sulphate-Carbonate Ratio

The question of sulphate-carbonate ratio has been raised in connection with the possibility of embrittlement in boilers operating at pressures above those considered at the time the A. S. M. E. Code of "Suggested Rules for the Care of Power Boilers" was issued. This company cannot state specifically what ratio would be required to insure absence of caustic embrittlement at high pressures. Further, there are little data on which to base a conclusion, since the mechanism of caustic embrittlement has never been demonstrated. It would, therefore, appear that there was little to do other

STATEMENT BY THE COMBUSTION ENGINEERING CORP., 200 MADISON AVE., NEW YORK, N. Y.

Boilers

Generally speaking, the horizontal water tube boiler is a more efficient heat absorber than the vertical boiler, and it is capable of higher rates of driving without priming. For moderate rates of operation with feed water containing scale forming solids, where turbining and washing of the boiler is necessary at frequent intervals, undoubtedly the bent tube or vertical boiler is preferable. For extremely high pressures the vertical boiler has a definite advantage in that the structure is more flexible and less likely to cause trouble with leaking tubes.

The sinuous header and vertical two and three drum boilers are adapted to pressures up to 1500 lb. or thereabouts. The four drum boiler is not included in this classification because of the additional drum and high price. In general riveted drums are used up to 450 lb., and forged or hammer welded drums for higher pressures. The box header boilers and the horizontal tubular boilers are limited to pressures up to about 250 lb.

The New York Edison Company—East River Station

The three steam generating units for the East River Station of The New York Edison Company are noteworthy because of the high steaming capacity for which they are designed, each having a guaranteed maximum capacity of 800,000 lb. per hr. Normally they will operate through a range from 500,000 to 700,000 lb. per hr. Each boiler, Fig. 34, is designed for 500 lb. pressure with a normal drum pressure of approximately 425 lb. Elesco superheaters will be installed to deliver steam at a total temperature of approximately 725 deg. fahr. Each of the boilers will be of the double-ended, bent-tube type, with four upper water and steam drums and four lower water drums for the complete unit; all drums will be 54 in. in diameter. Steam will be delivered from the two 54-in. upper rear drums into two 48-in. diameter dry drums; from these the steam will pass through a header to the superheater. Each of the three boilers, together with the integral economizer, water-cooled furnace walls, and water-cooled slag screen, will comprise a total area of 67,470 sq. ft. of heat-absorbing surface. Each boiler will be equipped with two plate type air preheaters, each of which will have a total area of 41,360 sq. ft. The furnace will have a volume of approximately 39,000 cu. ft. The unit will be fired by twenty vertical Lopulco burners, ten burners on each side of the furnace. It is expected that the gas temperature leaving the air preheater will range from 365 deg. fahr. at 500,000 lb. per hr., up to approximately 400 deg. fahr. at 800,000 lb. per hour.

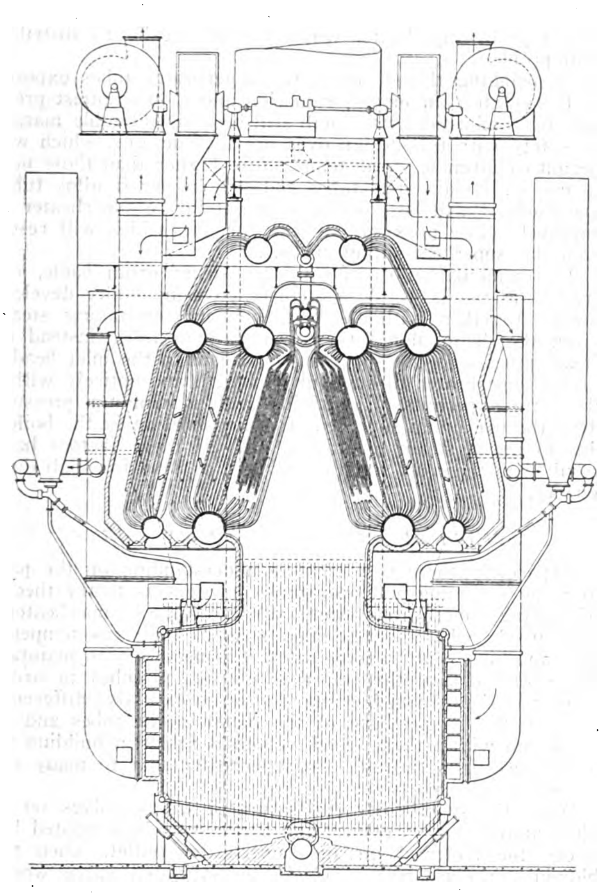

FIG. 34—800,000 Lb. Steam Generating Unit for New York Edison Co., East River Station, Combustion Engineering Corp.

The Philip Carey Co.—High-Pressure Units

Two high-pressure steam generator units are being built for the Philip Carey Company. Each of these units will be designed for a steaming capacity of 150,000 lb. per hr. at an operating drum pressure of 1840 lb. The steam will be superheated to a temperature of 825 deg. fahr. The boilers will be pulverized fuel fired and will have a completely water-cooled furnace. The combustion rate will be held down to a moderate figure.

Slagging

Continuity of boiler operation is largely in the hands of the operators except insofar as the designer has over-rated the boilers or furnaces for the conditions to be met. The two most frequent causes for interruption of operation are fouling of the internal surface of the boiler and fouling of the gas passages with ash or accumulation of large masses of slag in the furnace. The condition of the interior of the boiler is a problem for the operators and can be taken care of within definite limits on any particular job by treatment of the feed water, proper control of the steaming rate at which the boiler is operated, control of boiler water concentration and systematic washing or turbining of the boiler tubes. To minimize fouling of the gas passages, particularly in the front bank of boiler tubes, more moderate combustion rates and complete water cooling of the furnace are recommended.

Probably the most definite limitation to continued operation is the plugging of the first pass of the boiler due to the accumulation of slag or ash on the tubes. There are five contributing causes for these accumulations:

1. Melting point of the ash.
2. Temperature of the gas entering the first pass of the boilers.
3. Velocity of the gas.
4. Carbon in the gas.
5. Gas composition as to relative content of oxygen and carbon monoxide.

Of these items, the last four are directly dependent on the combustion rate, and it is believed they have an accelerating effect on the ash accumulation on the tubes. Obviously, the remedy is reduced combustion rate.

Water Walls and Screens

The problem of cooling pulverized coal-fired furnaces by water-cooled walls and slag screens is exceedingly complex, and although the design of the slag screen has a great effect in keeping the ash below the screen at a temperature below the slagging temperature, the distribution of the flame, the location of the hot zone, the turbulence in the furnace and the fineness of the coal, all have a contributing effect. In some instances a double slag screen was installed with two rows of tubes, each row spaced 10.5 to 14 in. apart horizontally, the two rows being staggered and located 10 to 12 in. apart vertically. This is a logical extension of the basic idea, the additional cooling surface being of value in lowering the ashpit temperature.

An important point which has often been overlooked is that the cooling effect of water-cooled walls is much greater on small furnaces than on large furnaces. In other words, the cooling effect may be expressed as a function of $\frac{A}{V}$, A being the projected area of the walls and boiler surface facing the furnace, and V the volume of the furnace in cu. ft.

Quality of Steam

One of the important problems is the delivery of steam having negligible moisture content to the superheater. In the past few years, operators and manufacturers have coöperated to the extent of securing much higher outputs from boilers without proper regard to steam quality until after the installation was completed. This has intensified the study of baffles to reduce the moisture content.

During the past year this company has made studies and experiments along this line, and progress is being made, though not as rapidly as desired. It is necessary to study at the same time the concentration in the boiler since there is a relation between the quality of steam and the concentration of dissolved and suspended solids in the boiler water. In this connection the matter of feed water control is very important. The usual automatic control by water level in the boiler is entirely inadequate for the high capacity boiler unit. This company is investigating water control by steam flow; some regulator companies are also developing regulators of this type. This is extremely important, and it is believed that eventually a satisfactory regulator must be developed that will proportion the boiler feed water to the actual steam output with, perhaps, an auxiliary or check control by water level.

It is believed that water walls tend to decrease steam quality because of the extremely large volume of water passed into the drum from the walls and the high velocity of the mixture entering the drums. An attempt is being made to minimize this effect by a different distribution of the riser connections to the drum and raising the point of entrance so that the moisture discharge from the water walls will not necessarily pass through the water in the drum.

Sulphate-Carbonate Ratio

This company has made no original investigations on caustic embrittlement, but Professor Straub of the University of Illinois has been consulted in a number of cases where caustic embrittlement has been found. Apparently no recommendations have been made of the sulphate-carbonate ratio for pressures in excess of 450 lb., at which pressure the recommended ratio is 4.5 or 5 to 1. This indicates a prohibitive ratio for pressures of 600 lb. and higher. This company's view is that up to 340 lb., proper control may be had by the sulphate-carbonate ratio and that for pressures in excess of this, there is promise in obtaining the required inhibition by trisodium phosphate. It is this company's opinion that no attempt should be made to operate boilers at pressures of 1200 lb. and over unless 100 per cent condensate is available or unless the feed make-up is evaporated water.

SUPERHEATERS

STATEMENT BY THE BABCOCK & WILCOX COMPANY, 85 LIBERTY ST., NEW YORK, N. Y.

1928 *Design of Superheater*

In the 1928 design of B. & W. superheaters there is but a single row of tube holes in the inlet and outlet headers, each tube being continuous from the inlet to the outlet without intermediate boxes. The total pressure drop thus occurs in the flow of steam through the tubes without intermediate points interfering with the distribution thus obtained. This construction further eliminates the necessity of distribution baffles or ferrules. With this design, short radius tube bends which would maintain a proper cross-sectional area through the tube in the bend and also maintain the proper tube gage on the bend are required, and a new method was developed by this company to make this construction possible.

While it is appreciated that the majority of superheaters in high duty plants seldom, if ever, require cleaning, the evidence is that occasionally something unforeseen occurs when such cleaning is necessary, and the new type of superheater is designed to permit thorough turbine cleaning. This is accomplished by the use of a Y-type return bend on one end of each loop, each Y being fitted with a valve of simple and approved design which can readily be opened for turbining. The location of these valves is such as to be outside of the range of stresses caused by heating and cooling, the entire fitting being protected from soot and ashes. The superheater as arranged is completely drainable. Where temperatures are beyond the limit where expanded joints will remain tight, the outlet superheater tubes can readily be welded to the header.

One of the design problems in connection with minimum pressure drop in superheaters is that of proper steam distribution. In the new design the steam is brought from the drum to the inlet header through a number of tubes arranged with approximately equal spacing along the length of the header, the tubes being located inside of the tube doors. This method of bringing the steam to the inlet header not only gives an improved distribution of the steam, but also eliminates the necessity of either a dry pipe or dry box within the steam drum of the boiler. Further improvement in distribution is obtained by making use of a large diameter outlet header, a source of supply for such headers now being available. The combination of these features results in a type of superheater which has practically no distribution problem.

By bringing the steam to the superheater tubes exposed to the greatest amount of radiation and to the hottest products of combustion, there will still be a considerable margin of safety with this design over previous designs, which will permit of ultimate steam temperature higher than those now in use with plain steel tubes and still higher if alloy tubes are used; it will be possible to maintain the superheater in relatively close proximity to the furnace, which will result in a flat superheat-output curve.

The combination of the shutter steam drum baffle, described in the B. & W. statement covering boiler developments, together with the arrangement for taking steam from the drum along its length through tubes instead of steam pipes, and the supplying of steam to the inlet header of the superheater throughout its length and entirely within the setting, permits of obtaining with a minimum pressure drop the maximum superheat for any location in the boiler, due to better steam separation. All of these factors have resulted in the most satisfactory type of unit for high duty service.

Setting of Superheater Safety Valves

Apparently there is a lack of understanding on the part of some designing and operating engineers as to the theory of setting superheater safety valves. In all superheaters, particularly where located in a zone of high gas temperature and high heat transfer rates, it is necessary to maintain a certain velocity through the superheater tubes in order to protect them from burning, due to an excessive difference between the temperature of the metal in the tubes and of the steam within them. Such velocities result in building up a pressure drop through the superheater that to many engineers seems excessive.

Were the superheater and saturated safety valves set to blow at the same pressure, and a pressure drop existed between the boiler drum and superheater outlet, when the blowing pressure was reached, the saturated valve would blow first and the superheater would have no flow, or little flow, of steam through the tubes for their protection. It is necessary to set the superheater safety valves at a pressure below that of the saturated valves in order that the superheater valves may blow first, insuring a sufficient flow of steam through the superheater at all times.

Other conditions which make lower superheater safety valve setting necessary occur in installations where a number of boilers are connected to a common steam main. Under such conditions, if a saturated valve were to blow before a superheater valve, all of the steam generated by the boiler blowing would not pass through the superheater and the amount of superheat would increase. On slacking back the fire in order to cause the safety valve to shut, a smaller and smaller amount of steam would pass through the superheater, and there would be a corresponding increase in the superheat. Where non-return valves are used between the boiler and the steam main, it is possible for such valves to close on the lowering of pressure in the boiler, after which there would be no flow of steam through the superheater until the pressure is raised to that in the main and the non-return valve opened. Under such conditions it is possible for the superheater tubes to be overheated.

STATEMENT BY THE FOSTER WHEELER CORP., 165 BROADWAY, NEW YORK, N. Y.

In one of the designs of radiant heat superheaters manufactured by this company, heavy-wall rectangular-section forged steel elements are used. These elements are spaced about ¼ in. apart and are backed up by refractory and insulating material, steel casing plates and a reinforcing steel frame. In general, all construction and maintenance problems originally encountered in the development of this type of superheater have been solved, and about 200 are now in satisfactory operation.

The principal difficulties that had to be overcome may be summarized as follows:

1. Overheating of elements due to internal scale, insufficient steam velocity, lack of uniform steam distribution to all elements, and improper operation when taking boilers on or off line.
2. Deterioration of elements due to internal strains resulting from heating of elements on only the one side exposed to the furnace.

About two years ago another design of radiant heat superheater was brought out. In this type relatively thin-wall circular-section elements are used. They are spaced about 3 in. apart and about 10 in. out from refractory walls. This spacing is such that ash does not build up rapidly on the brick behind the elements, nor across the spaces between adjacent elements. Ash that does accumulate does not attack the brick, and is easily removed by permanent disappearing soot blowers or by hand lancing. Heat absorption on the side of the elements away from the furnace is sufficient to eliminate any trouble due to distortion or unbalanced internal strains from uneven heating. Under comparable conditions the heat transfer per square foot of surface around the entire circumference of the circular elements is practically the same as the transfer per square foot on the furnace face only of the rectangular elements in the old design. The effective surface per square foot of wall space occupied and, therefore, the work that can be done is about 30 per cent greater in the new than in the old design.

About 46 radiant superheaters of the new design are installed or on order. For steam temperatures up to 750 deg. fahr., chrome-vanadium steel elements, costing in standard sizes three to four times as much as low carbon steel boiler tubes, are recommended. For higher steam temperatures it would ordinarily be advisable to use high chrome-nickel alloy elements costing ten or more times as much as low carbon steel boiler tubes.

For central station service the Foster Wheeler Corp. is prepared to offer convection or radiant superheaters, separately or in combination for steam temperatures up to 900 deg. fahr. Higher steam temperatures increase the importance of a flat curve of superheat versus rating, and in this connection it is desired to point out that the use of series combination convection and radiant heat superheaters is a means of holding steam temperature within a safe operating range under varying load and combustion conditions that is preferable to the use of sprays or other desuperheating devices for accomplishing the same results.

STATEMENT BY THE SUPERHEATER CO., 17 EAST 42ND ST., NEW YORK, N. Y.

During the past year no striking changes in the design of Elesco superheaters have been attempted. As larger and larger steam units are being designed, the keynote becomes continuity of operation. Therefore, attention has been devoted toward improvement of the small details which make for lower maintenance and outage charges. To the latter end alloy steel bolts are used as standard for superheater supports located in the high-temperature gas zones. In the design of the supports themselves high heat-resisting alloys are being used more extensively.

Another important point is equalization of tube wall temperatures. This company's standard practice is to locate the coolest portion of the units (through which the steam first passes) in the hottest gas zone and the hottest portion (through which the hottest steam passes) in the cooler zone. Even with the increased transmission in the hottest zone, the metal temperature is cooler than in the balance of the unit. In addition to the above, it has been found necessary to design more intricate baffles to provide for the increased expansion of the larger units.

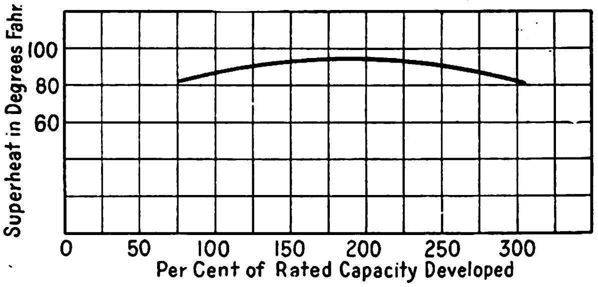

FIG. 35—CHARACTERISTIC SUPERHEAT-OUTPUT CURVE, THE SUPERHEATER CO.

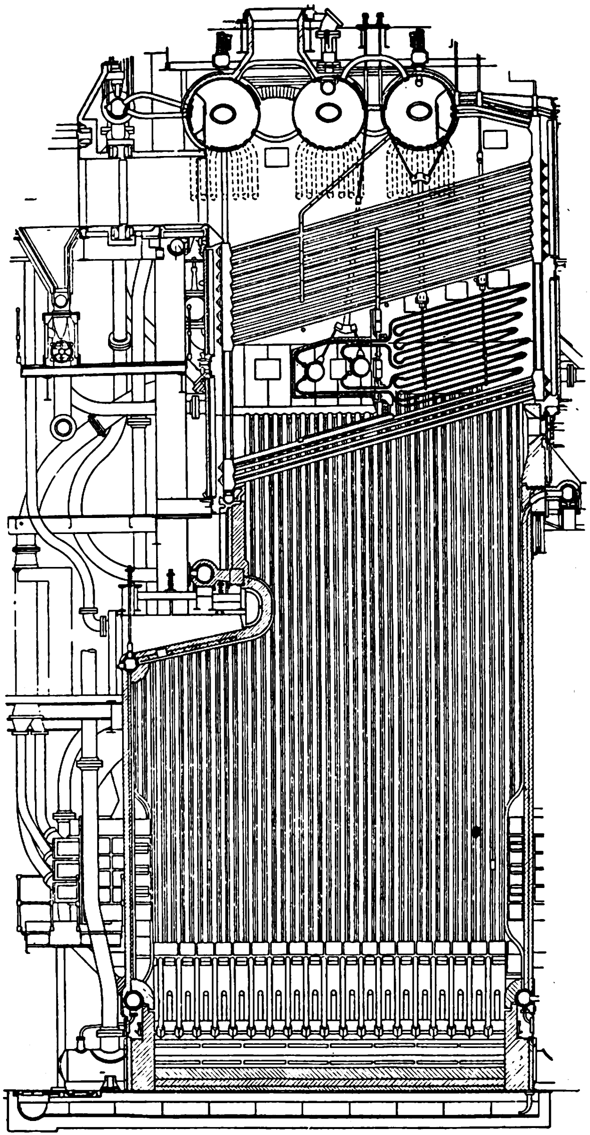

FIG. 36—1928 HELL GATE SUPERHEATER INSTALLATION, THE SUPERHEATER CO.

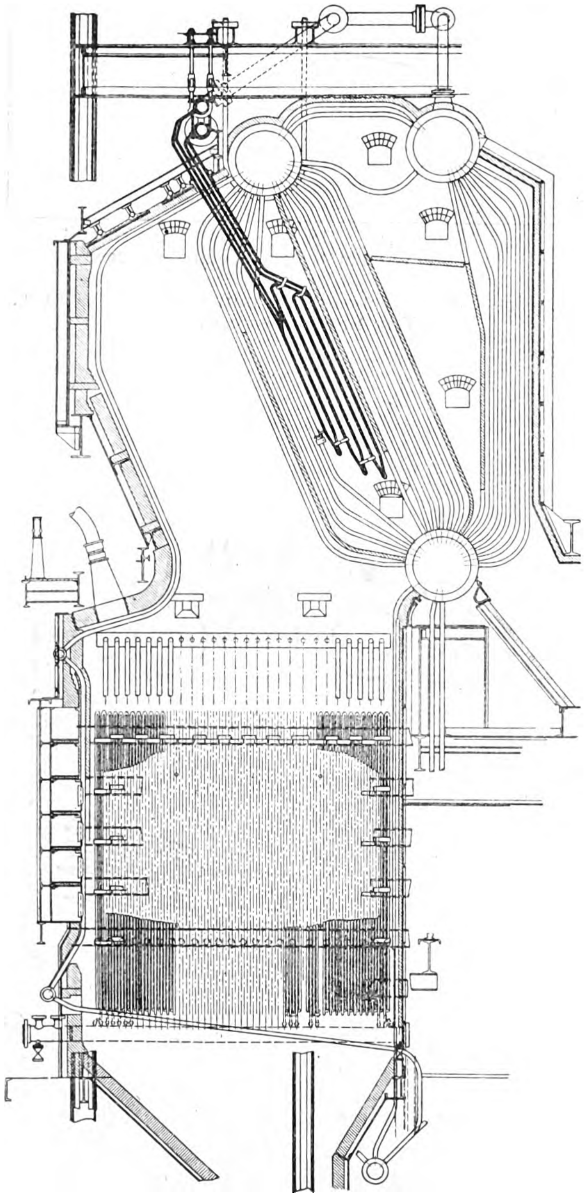

FIG. 37—RECENT SUPERHEATER INSTALLATION, NORTHEAST STATION, KANSAS CITY POWER & LIGHT CO., THE SUPERHEATER CO.

Increasing appreciation of the fact that the superheater is a device to superheat steam and not to evaporate moisture is shown by the greater use of steam purifiers. The problem of delivering dry steam has been intensified by the extensive use of water walls.

The necessity for having clean, dry steam enter the superheater increases with higher pressure and temperature stresses. The revelation that high-pressure boilers must have the purest feed water obtainable if tube failures are to be prevented has focused attention on the superheater, in which pressure and temperature stresses are much higher and into which scale-forming matter must be prevented from entering. This company's standard practice is to limit the moisture content of steam entering the superheater to 1 per cent. Experience has amply indicated that, when high steam velocities are used, the solids contained in 1 per cent moisture will not be deposited on the superheater tube wall. Experience may later indicate that it is necessary to lower the moisture specification for the highest pressures. The plant designer is well advised if he limits the moisture content to ½ of 1 per cent or less for 1400 lb. pressure and above.

Final steam temperatures have been limited to 750 deg. fahr. up to the present. However, superheaters are now being designed for one installation to operate at 775 deg. fahr. and another at 825 deg. fahr. With clean steam and careful supervision there is no great increase in the hazards of operation at 800 deg. fahr. as compared with 750 deg. fahr.

Fig. 35 shows the superheat curve for an Elesco radiant superheater, screened by 4 in. o. d. water wall tubes on 8 in. centers.

Outstanding superheater installations during the past year are listed below:

United Electric Light & Power Co.—Hell Gate Station, Fig. 36. These superheaters are designed to superheat a maximum of 400,000 lb. of steam per hr. at 285 lb. pressure to a final temperature of 705 deg. fahr.

Kansas City Power & Light Co.—Northeast Station, Fig. 37. This installation included a primary convection superheater operating at 1350 lb., 725 deg. fahr., and a radiant superheater, as a reheater, operating at 295 lb., 720 deg. fahr.

Detroit Edison Co.—Trenton Channel Station. Fig. 38. This superheater is designed to superheat a maximum of 360,000 lb. of steam per hr. at 420 lb., 720 deg. fahr. The

feature of this installation is the use of radiant loops in series with convection loops to obtain a more uniform superheat than can be obtained with a full convection type.

Steam Reheaters

That steam reheaters are a practical method of reheating steam is demonstrated by performance to date. Interest in this method is evidenced by the increasing use at pressures up to 1800 lb. Fig. 39 shows the latest design of Elesco steam reheater at the Crawford Avenue Station, Commonwealth Edison Co., Chicago. This company has made extensive studies of reheater design and has arrived at the conclusion that the simpler types will not give the continuity of service which is demanded. The very small number of joints in this design is a feature.

Due consideration must be given to the fact that heat transfer in the high-pressure side in the desuperheating zone is quite different from that in the condensing zone. A high steam velocity is necessary in the desuperheating zone and a low steam velocity in the condensing zone.

ECONOMIZERS

STATEMENT BY THE BABCOCK & WILCOX CO., 85 LIBERTY ST., NEW YORK, N. Y.

A development in economizer design of last year was a change in the design of return bends. These bends were formerly made of seamless steel tubing with threaded flanges on the ends having female facings; the bends are now forged from round bar stock with the flanges integral. The flanges are produced on the ends of the bar by the upset forging process. After the flanges are formed and before bending, the blank is drilled from end to end, making it a seamless tube. Special devices are used in forging and bending to insure the faces of the flanges being in the same plane after bending and having the same angularity, as well as maintaining uniform center distances of the ends.

The return bends for connecting the top and bottom rows of tubes to the headers were formerly made of seamless steel tubing with threaded flanges on each end, one end having male and the other female facing. In order to eliminate threaded flanges throughout on the return bends and at the same time to produce a return bend for the header connections more adaptable to the location than the solid forged bend, a type has been developed having loose flanges and facings similar to the Van Stone type. These bends are of seamless tubing, upset on the ends and having loose fitting bolting flanges bearing against the upset ends, one end being faced for male and the other for female connection.

STATEMENT BY THE COMBUSTION ENGINEERING CORP., 200 MADISON AVE., NEW YORK, N. Y.

This company is developing as rapidly as possible a standard line of straight tube economizers, using both 2 and 2.5 in. tubes, designed for pressures up to 2000 lb. The flexible design of a parallel series of tubes connected at the ends with return bends or expanded into junction boxes and expanded at the inlet and discharge ends into inlet and oulet headers has been definitely adopted. Each vertical coil, composed of return bends and straight tubes, is thus free to expand without stress in the bends or tube joints.

The junction boxes and return bends are outside of the gas passage and separated from it by cast iron plates. Stuffing boxes are provided where the tubes pass through the plates to insure against gas leakage and leakage of vapor from the junction boxes into the gas stream. The return bend connection is similar to an ammonia bend and is held to the tube by two bolts.

In the junction box type the junction box is a rectangular steel forging provided with oval handholes and caps opposite each tube. The latter type is in service at Kansas City and is operated under pressures up to 1880 lb. This high pressure is due to the fact that only one boiler is in use and that the motor speed is a little higher than expected. Changes will be made in the pump to reduce the excess pressure.

STATEMENT BY THE FOSTER WHEELER CORP., 165 BROADWAY, NEW YORK, N. Y.

In the April, 1926, report of the Prime Movers Subcommittee on Boilers, Superheaters and Economizers (N. E. L. A. Publication No. 256-11) a statement was made to the effect that investigations then indicated the life of Foster economizers could be safely estimated at from 15 to 20 years, depending upon inlet water temperature and quality of make-up water used. Later experience tends to confirm the correctness of this statement. For analysis of the reasons in back of it, only three causes of deterioration need be considered. These are:

1. Internal corrosion of elements
2. External corrosion of elements
3. Deterioration of casings.

Internal corrosion will be practically nil, if the oxygen content of water entering economizers is not over 0.2 c.c. per liter and if the hydrogen ion concentration or pH value is not less than 10. These conditions can be easily and regularly checked and maintained. Oxygen contents and pH values can both be determined with sufficient accuracy by means of simple and rugged apparatus permanently installed in or adjacent to the boiler room rather than in a distant laboratory. The installation and regular use of such apparatus by operating engineers is strongly recommended because it will inevitably better plant performance in respect to these two items. In this connection attention is called to an instructive article, "Hydrogen Ions Are the Key to Corrosion," by Messrs. A. A. Markson and Paul Fritz of the New York Steam Corp., which appeared in *Power*, Feb. 5, 1929.

External corrosion of elements will not be a factor in the life of economizer elements unless in operation gases are cooled below the dew point, or if, during shutdown periods, moisture is deposited on the elements by washing or by condensation from atmosphere and is not thoroughly dried before economizers are again put into operation. Some years ago the washing of Foster economizers was recommended. It has been found possible to discontinue this practice with certain fuels and that economizers can be kept clean, and contract heat transfer rates maintained in installations where soot blowers only are used for cleaning. When so operated Foster economizers are adequately protected against external corrosion of elements under all contingencies by shrunk-on, gilled cast iron rings, which completely cover the steel tubes and prevent any contact between them and sulphur bearing gases.

Foster economizer castings are made of flanged cast iron sections, with machined metal to metal joints about 2.5 in. wide, externally bolted together. The end and intermediate supporting tube sheets are also of cast iron so that in casings, as on elements, gases contact only with cast iron parts. This provides a casing that is practically indestructible, will resist any corrosion to which it might be subjected in normal operation, can be made gas tight, and will show less than ½ of 1 per cent loss of CO_2 from economizer inlet to outlet.

In this connection it may be noted that in a certain installation where Foster economizers replaced old cast iron vertical tube economizers without any change in induced draft fans, not only was the overall boiler unit efficiency improved, but the maximum steaming capacity per boiler was definitely increased from 140,000 to 165,000 lb. per hr., or about 18 per cent. This was due not to additional work done in economizers, but almost entirely to elimination of air infiltration into economizer casings and consequent reduction of load on fans per unit of steam generated.

Fig. 40 shows a Foster economizer with a cast iron sectional housing and access doors. Above the economizer is one of the new sectional, plate type Foster air heaters, the first which has been put into operation during the past year. The clips on the sides of the air heater are for holding in-

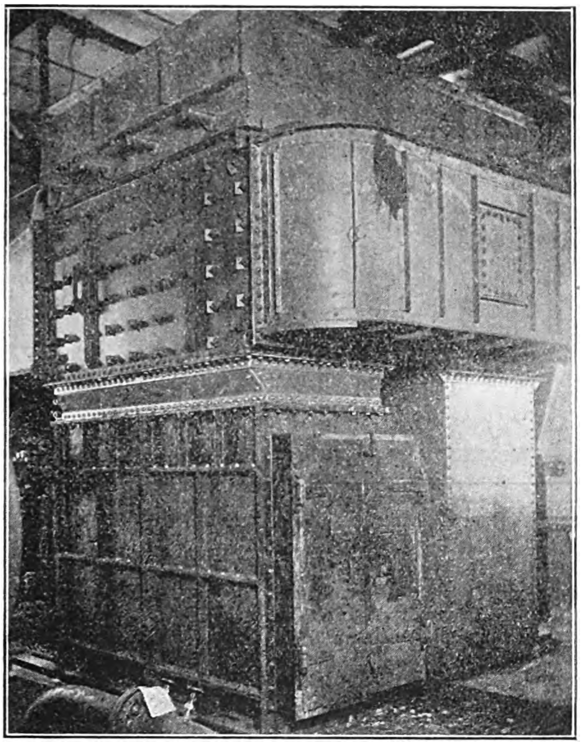

FIG. 40—FOSTER ECONOMIZER AND AIR HEATER, FOSTER WHEELER CORP.

sulation in place; the tubular projections above the air heater section house the ends of the soot blower elements providing for longitudinal movement during blowing.

The gases pass straight up through the economizer and air heater section, then to the right through the steel casing shown at the top and downward through a second air heater section and into the rectangular cinder catcher shown at the right of the economizer.

STATEMENT BY THE B. F. STURTEVANT CO., INC., HYDE PARK, BOSTON, MASS.

There have been no radical changes in the design of plain cast iron tube economizers for a number of years. There has been more of a demand for tubes in a horizontal position, although they can be furnished in both horizontal and the old vertical position. In the case of the horizontal position the economizers are built in two ways: with the headers vertical and the tubes horizontal, or with both headers and tubes horizontal. The latter is far more preferable as it greatly simplifies the installation.

Care must be used in installing any economizer of the vertical header-horizontal tube type to make sure that the water flow is upward. Installing them with the water flow downward is not recommended as convectional currents are set up in several of the different paths of water flow. The surface becomes ineffective in these paths, and there is the possibility of the formation of steam and breaking of the parts, particularly the bends. This is particularly true at low ratings where the velocity of flow is not great enough to overcome the convectional currents which are trying to force their way upward. As the flow increases, the convectional currents are overcome and the danger is eliminated.

This difficulty is not present in the second arrangement of apparatus where both headers and tubes are horizontal, for the reason that there is but one bend connecting each level and the water is forced through this bend at such high velocity that it overcomes the action of the convectional current. Another feature of this arrangement is that the water comes in at one end of the headers and leaves at the opposite end of this section. Thus, even if there is stratification of gases, the temperature of the water in each succeeding level is increased by steady increments.

During the last three or four years soot blowers have been adopted for cleaning cast iron economizers. Heretofore scrapers have been used for the vertical tube type, but it has been found that there is an appreciable amount of air leakage which tends to overload the fans. The present knowledge of combustion permits far more accurate calculation of gas quantities than heretofore, and therefore purchasing engineers are selecting fans with but little margin of safety. Air excluders were sometimes resorted to, but these are not thoroughly effective. Soot blowers can be installed to operate in tight bushings, thus reducing leakage to a minimum. Even though this means the loss of a certain amount of scraper business incidental to economizer sales, this construction has been recommended in the interest of better performance and reduced cost of fan equipment.

Excellent results have been obtained in the application of extended surface steel tube economizers. The relative rates of heat transfer with plain and extended surface are shown in the test curves of both types plotted with velocity as abscissas. The slope of the transfer curve with the plain type is greater than the slope of the curve for the extended surface type. The disk making the extended surface has been so designed that there would not be more than a slight difference in temperature between the outside diameter of the disk and the tube, as this surface becomes less effective the further the distance from the tube. A steel disc pressed onto the tube is as efficient as if it were part of the tube itself and being of similar metal there is no difference in coefficient of expansion. These economizers show continuous operating results, proving that the contact between the tube and the disk is absolutely tight and permanent.

No difficulty has been experienced in maintaining clean surfaces in these economizers, and test results show that the machines can give continuously efficient service in accordance with their guarantees.

SOOT BLOWERS

STATEMENT BY THE DIAMOND POWER SPECIALTY CORP., 10340 OAKLAND AVE., DETROIT, MICH.

The development of a new process for manufacturing calorized soot blower elements was mentioned in last year's statement. After another year of service, these elements have proved to be more successful than was anticipated. Their life is not only very much longer, but they are usable at considerably higher temperatures. Fig. 41 shows the condition of a "New Process" calorized element after seventeen months' service, at a location where the temperatures are close to 1800 deg. fahr.; namely, at the top of the first pass of a Stirling boiler, back of the front bank.

For the hottest locations in the lower part of the first pass, Dialoy continues to be the only successful material. The successful production of seamless Dialoy elements in conjunction with an improved nozzle construction have increased their successful application. Further extended experiments on alloys of the heat resisting group confirm previous conclusions that no other alloy at present available can compare with Dialoy for high-temperature boiler service. That this alloy is immune to attack by the sulphur in the gases is particularly important.

The use of Dialoy bearings with Dialoy elements has now become general practice with this company. A particularly important development in this connection is the welding of these bearings directly to the boiler tubes. This construction is particularly suitable for hot locations, and it has proved entirely practical to weld Dialoy bearings to boiler tubes. Electric arc welding with Dialoy rod is used. This practice has been sanctioned by the Hartford Steam Boiler Inspection & Insurance Co., the welding being subject to approval by their inspection force.

Fig. 42 shows a soot blower element mounted in Dialoy bearings welded directly to the boiler tubes. As typical of the locations in which this construction is most satisfactory,

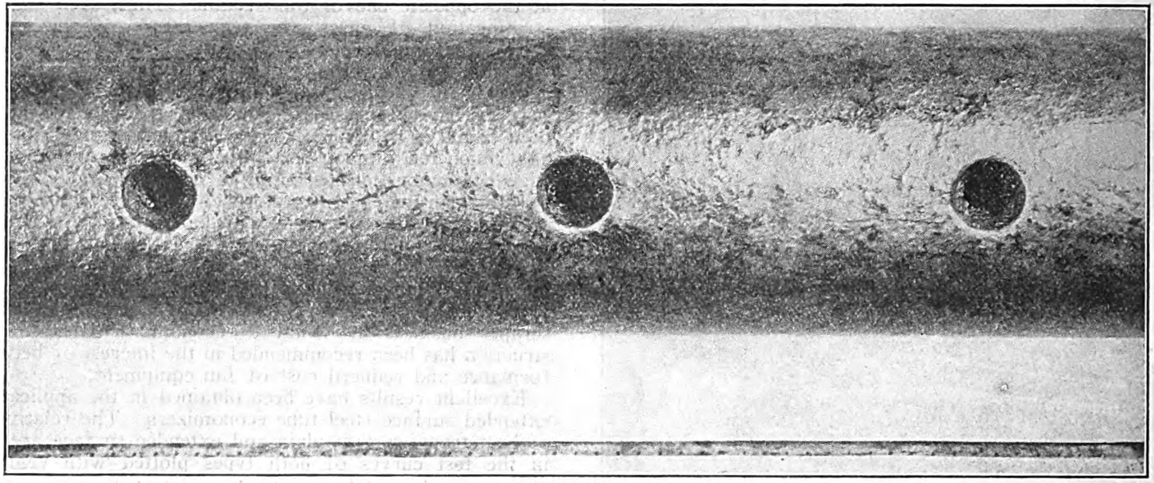

FIG. 41—"NEW PROCESS" CALORIZED SOOT BLOWER ELEMENT AFTER 17 MONTHS' SERVICE AT ABOUT 1800 DEG. FAHR., DIAMOND POWER SPECIALTY CORP.

Fig. 43 shows an installation made some twenty months ago; the unit designated as A is a Dialoy unit and was installed primarily for slagging purposes. The results of this installation have been entirely satisfactory.

The use of compressed air for blowing large boilers has been extended during the past year. Two large installations in central stations have been made; cleaning results are reported as satisfactory. The most important point is the maintenance of the maximum blowing pressure at all times, necessitating large piping and adequate storage facilities. It appears that air is being considered more frequently than heretofore, and it is probable that its use as a cleaning medium will be extended.

A series of investigations has been completed during the past year covering various phases of soot blower performance. The plants investigated are widely distributed and operate under varying conditions of fuel and load. It is thought that brief abstracts of the most pertinent data gathered in these studies will be of interest.

Decatur

At the Decatur Station of the Illinois Power & Light Corp. four 6000 sq. ft. Stirling boilers are used to supply saturated steam at 150 lb. gage pressure for heating purposes. The plant operates about 210 days per year. Fuel is Illinois screenings having a heat value of 13,000 B.t.u. dry basis. Average loads are 200 per cent. (6.7 k-B.t.u. per sq. ft. per hr.) rating.

A study was made in this plant of the relative efficiencies and cost of the hand lance method of cleaning as compared to the use of soot blowers. Hand lancing was formerly used entirely, and accurate data are available for comparison with present conditions under soot blowers. The total yearly cost of cleaning with soot blowers for all boilers is $936 as compared to $3,763 by hand lance methods. While the depreciation, interest and maintenance charges are higher for the soot blowers, the steam and labor costs for the hand lance method are much greater. The blowers maintain an average flue gas temperature of 395 deg. fahr. at the exit of the economizers. Hand lancing three times per shift was necessary to produce approximately this result. With the soot blowers, there is the further advantage of elimination of draft losses and furnace cooling which exists when the cleaning doors are opened for hand lancing, a not inconsiderable item where the boiler must be hand lanced three times per shift.

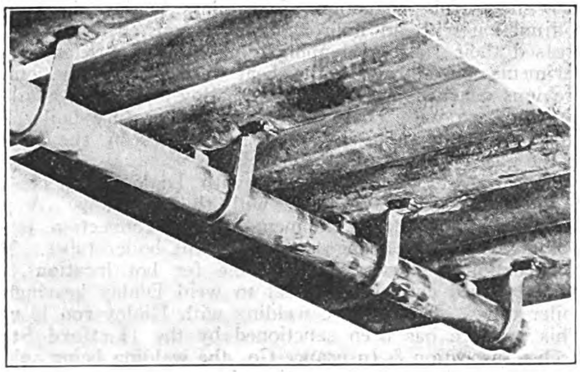

FIG. 42—DIALOY ELEMENT SUPPORTED IN DIALOY BEARINGS WELDED TO BOILER TUBES, DIAMOND POWER SPECIALTY CO.

Youngstown Sheet & Tube Co.

Five 7630 sq. ft. horizontal water tube boilers are fired with coke breeze at normal ratings of 173 to 200 per cent

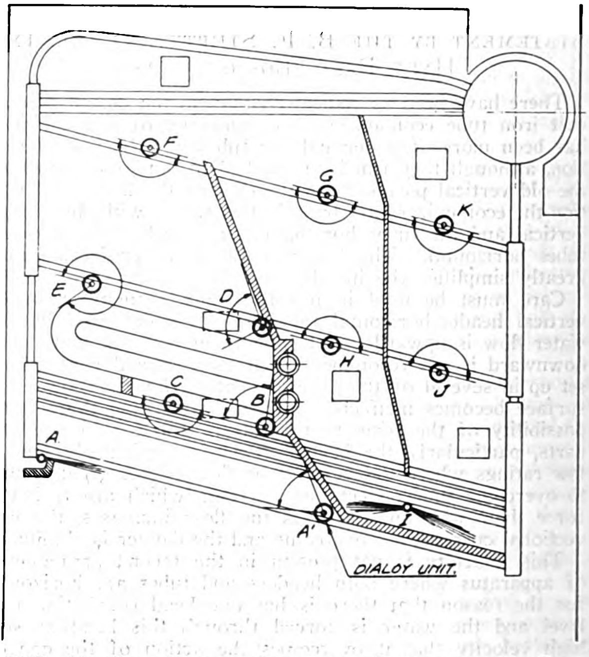

FIG. 43—SOOT BLOWER LOCATION, BOILER NO. 20, COLFAX STATION, DUQUESNE LIGHT CO.

(5.8 to 6.7 k-B.t.u. per sq. ft. per hr.). About 56 tons are burned per boiler per 24 hr., furnace temperatures of 2450 deg. fahr. being attained. Steam pressure is 175 lb. gage.

A severe slagging action takes place in the lower part of the first pass; one man on each shift rodding tubes continuously could not keep the deposit down, and drafts had to be increased until a positive pressure of 0.15 in. was produced in the furnace. This resulted in excessive stoker, door and furnace repairs and boilers could not be kept on the line over 10 days. The installation of one Dialoy slagging unit at the bottom of the first pass in each boiler has eliminated the difficulty. These are operated every 2 hr. and permit carrying of full loads with normal draft. The saving in de-slagging labor and repairs for the plant is $9,239 per year, to which may be added a substantial fuel saving.

Toronto

At the Toronto Station of the Pennsylvania-Ohio Power & Light Co. six 20,000 sq. ft. horizontal water tube boilers operate at ratings varying from 260 to 300 per cent (8.7 to 10 k-B.t.u. per sq. ft. per hr.). Pulverized coal is used, each boiler burning about 200 tons per 24 hr. Steam pressure is 385 lb. gage with superheat of 265 deg. fahr. An outline sketch of one of the boilers with the soot blower locations is shown in Fig. 44. The blowers are operated each shift, requiring 1 hr. of labor and 7440 lb. of steam per 24 hr.

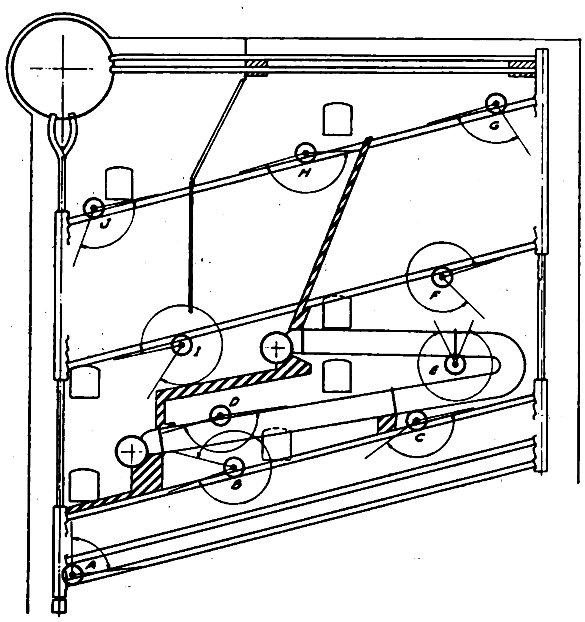

FIG. 44—SOOT BLOWER LOCATION, TORONTO STATION, PENN-OHIO POWER & LIGHT CO.

Tests carried out on one boiler, operating at constant ratings of 287 per cent (9.6 k-B.t.u. per sq. ft. per hr.), indicate a rise of 25 deg. fahr. in exit gas temperatures beyond the air heater when the use of soot blowers is discontinued. All operating conditions were held constant throughout the test, so that the rise in uptake temperatures is a direct indication of fuel saving. This amounts to $1,016 per boiler per year. Although the lower fuel consumption represents a material saving, this is looked upon as secondary to the advantage of keeping the passes between tubes free. The user believes that it would be impossible to maintain present ratings without mechanical soot blowers. Draft conditions are such that opening the inspection doors along the first pass for lancing does not materially affect boiler operation, whereas to open doors in the second and third passes would seriously affect evaporation. It is estimated that, to keep the boiler on the line, 1¾ hr. of hand lancing would be necessary per shift in the first pass alone. It is thought that such hand lancing would have slight, if any, effect in lowering flue gas temperatures below that obtained at the end of the test above described. However, the annual cost per boiler of hand lancing the first pass only, would amount to $674 more than the present cost of soot blower operation for the entire boiler.

Hell Gate

At the Hell Gate Station of the United Electric Light & Power Co., tests were run to determine the increase in flue gas temperatures when operation of the soot blowers was discontinued. In this station there are two groups of large horizontal water tube boilers, the first of 18,900 sq. ft. and the second of 12,560 sq. ft. The latter group is equipped with economizers and water walls. West Virginia coal averaging 14,000 B.t.u. is burned on stokers. Ratings run from 200 to 300 per cent (6.7 to 10 k-B.t.u. per sq. ft. per hr.), the latter being the peak ratings and the former, average.

The outlet temperature of one boiler of each group was taken at different ratings after the operation of soot blowers. Soot blowing was then discontinued and the rise in outlet temperature noted. Results of the tests made on the 18,900 sq. ft. boiler are shown in Fig. 45. At the end of four days the rate of increase of outlet temperature on the 18,900 sq. ft. boiler was practically constant, and the soot blowers were then operated. The curves show the drop in outlet temperatures. Taking the curves for 225 per cent (7.5 k-B.t.u. per sq. ft. per hr.) rating, it will be noted that the maximum boiler outlet temperature reached is 675 deg. fahr. The average temperature for the first day of operation without blowers is 613 deg. fahr., this being the mean of the boiler outlet temperature obtaining just after the blowers were operated and just before they would normally be operated again. In other words, the blowers are normally operated once every 24 hr. on this boiler, and during this period the boiler outlet temperatures increase about 25 deg. fahr., consequently 613 deg. may be taken as the average outlet temperature when blowers are being used normally every 24 hr. This 62 deg. increase in boiler outlet temperature due to omitting operation of the soot blowers is equivalent to 1.9 per cent fuel saving, amounting to $3,161 per year. The total cost of soot blower operation per year for one boiler is $1,887, including all fixed charges, maintenance, operating labor and steam consumption, leaving a net annual saving per boiler of $1,273. This figure is based only on the actual fuel saving, and does not take account of the other advantages of soot blower operation, namely, the maintenance of proper draft conditions and higher operating ratings. These factors are difficult of exact evaluation but are, by a great many, considered of even greater importance than the fuel saving.

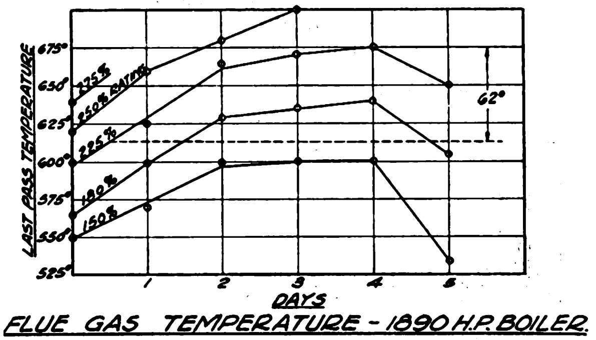

FIG. 45—RISE IN FLUE GAS TEMPERATURE AT HELL GATE AFTER DISCONTINUING SOOT BLOWER OPERATION FOR FOUR DAYS, DIAMOND POWER SPECIALTY CORP.

In the case of the 12,560 sq. ft. boiler equipped with water walls and economizer, the boiler outlet temperatures were rising at a practically constant rate, and there was no opportunity to continue the test to the point where this rise in outlet temperature would reach a constant level. Due to this fact and the lack of observation of the economizer outlet temperatures, the savings on this unit cannot be evaluated. The latter type of boiler is equipped with the automatic valved head, and the annual cost of operation of soot blowers on this boiler is estimated at $300 less than on the 18,900 sq. ft. boiler.

STATEMENT BY THE VULCAN SOOT CLEANER CO., DUBOIS, PA.

The Vulcan improved self-contained model "H" valve operating head is shown in Fig. 46, as re-designed to include the following changes: Accessibility, ample chain clearance, deep stuffing box, enclosed gear and flanged head, making it easy to mount or dismount the head. Use has been freely made of monel metal and stainless steel in order to reduce wear and corrosion.

One of the outstanding features of the head is the flange connection which is provided for connecting the operating head to the soot cleaner element. When ready to install the head, a flange weighing not more than 3 or 4 lb. is screwed on the end of the element. This is a big advantage, as all fittings and measurements can be made using this light-weight flange. When the assembly is complete the valve-operating head can be hoisted into place and attached by screwing on four nuts. In the past it has been necessary to lift the entire head into position in order to make the required measurements, and it was also necessary to turn the head or the element in order to screw the two together.

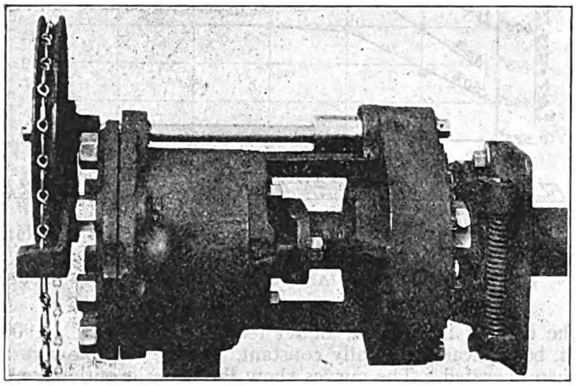

FIG. 46—MODEL "H" SOOT BLOWER VALVE OPERATING HEAD, THE VULCAN SOOT CLEANER CO.

With the flange connection this difficult operation is entirely eliminated. The soot cleaner elements, together with the sleeve mount, can be completely installed while the brickwork is going up. The installation of the heads themselves can be delayed until the bricklayers and other workmen are out of the way.

The model "H" head is driven through spur gears having an approximate ratio of 12 to 1; the gears are entirely inclosed, which does away with the necessity of cleaning them. There is never any danger of sticking and possible breakage due to clogged gear teeth which sometimes renders the operation of the head difficult and at times impossible. The stuffing box has been deepened to allow the use of six rings of packing, instead of four, and increased space has been left in front of the stuffing box to facilitate changing the packing. The chain or operating wheel of the cleaner head is located in a plane far enough away from the boiler wall for the chain to clear the steelwork on the side of the boiler.

The valve is an integral part of the head, and is a sliding disk type, self-adjusted for wear, with no tendency to stick. The valve is wide open while the element sweeps forward and back over the entire cleaning arc and closes steam tight when the work is completed. The valve is either of stainless steel or monel trim, the disk being made of a special material called "Nogall," which has high anti-friction properties under temperatures ranging from 700 to 800 deg. fahr. The use of this material has greatly reduced the effort needed to operate the head and eliminates the possibility of any damage to the valve seat under high pressure and temperature steam conditions.

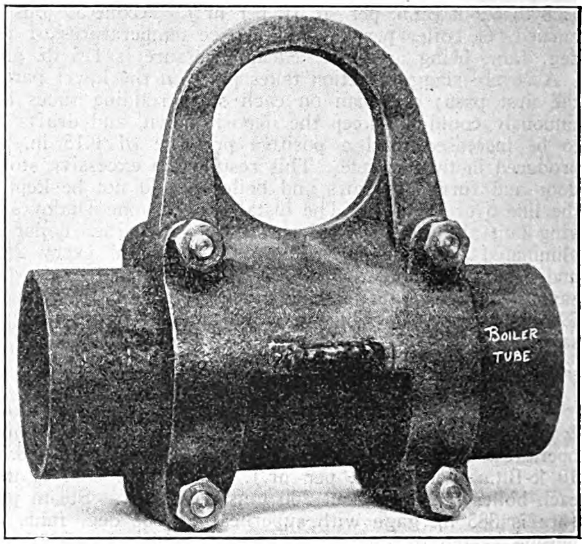

FIG. 47—SOOT BLOWER BEARING, THE VULCAN SOOT CLEANER CO.

The Vulcan intimate contact type of bearing is shown in Fig. 47. This bearing is an improvement over those offered for soot cleaner purposes in the past. It is so designed and constructed that the heat taken up from the boiler gases by the bearing, bolts and studs is rapidly passed on to the boiler tubes. This keeps the bearing comparatively cool at all times in practically any location in the boiler where it can be installed.

A view of a special steam soot blower for cleaning a tubular air heater recently designed for a central station is shown in Fig. 48. It is operated by a hollow rack through which the steam supply is led to the two headers which are equipped with steam nozzles. The two headers are held together by connecting pipes to which bearings are welded for the support of the four wheels on which the assembly runs. The rack is actuated by a small spur gear mounted on a vertical spindle which is turned the correct number of degrees to register the nozzles correctly with adjacent

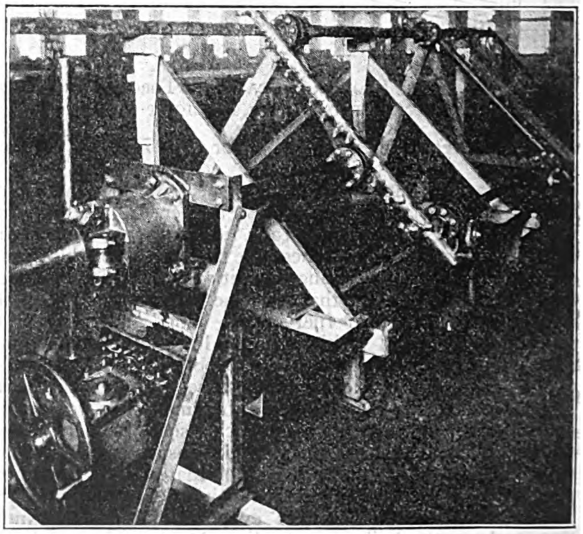

FIG. 48—SOOT BLOWER FOR TUBULAR AIR HEATER, THE VULCAN SOOT CLEANER CO.

longitudinal rows of air heater tubes. A visual indexing device is provided on the top of the gear box, made up of a disk having a radial slot. When the slot coincides with a corresponding slot in the cover of the gear box, indication is given of the traversing of one full space. The gear box which contains the reduction gears and the index mechanism is entirely closed and is filled with oil. The outer end of the rack is attached to three swivel joints.

The ratchet head shown in Fig. 49 is a re-design of the ratchet head exhibited in Fig. 50 of the 1922 report of the Prime Movers Committee. The springs which formerly actuated the pawls have been replaced by gravity action, the position of the pawls having been changed from bottom to top. A projection from the rear frame has been provided to cover and form a housing to prevent access of dust and dirt. The ratchet head has also been provided with a friction brake to avoid friction effect between the working frames and the element that would turn the element backward and thus prevent the engagement of the pawls with the ratchet wheel. This would sometimes occur where the elements were short.

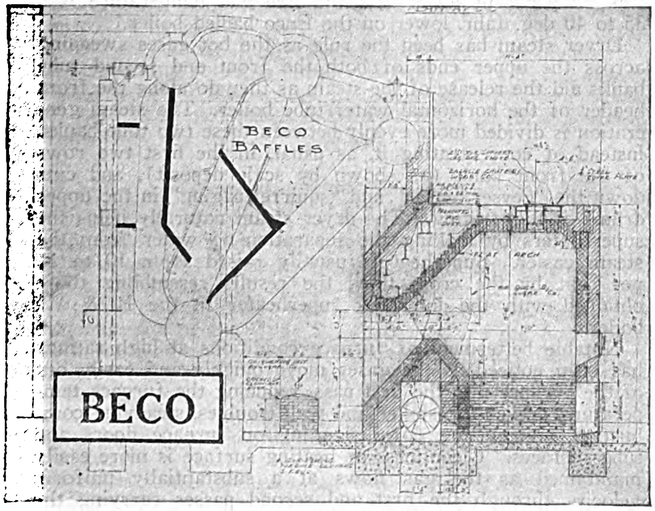

FIG. 50—BECO BAFFLE APPLIED TO CONNELLY BOILER BURNING BAGASSE, BOILER ENGINEERING CO.

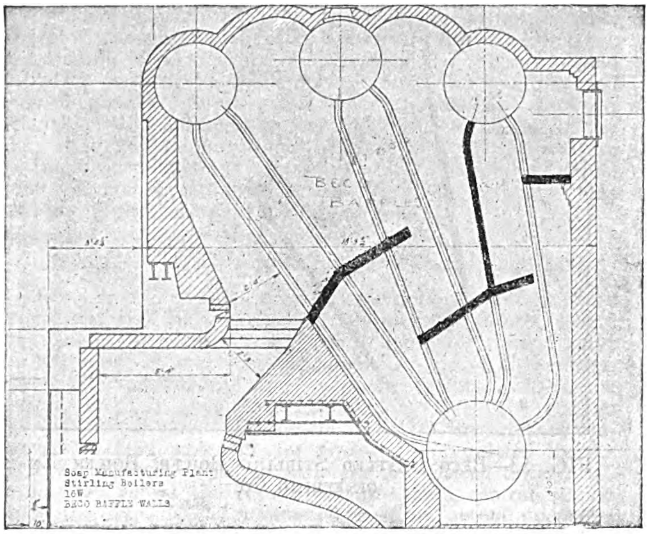

FIG. 51—BECO BAFFLE APPLIED TO STIRLING BOILER, BOILER ENGINEERING CO.

BAFFLING

STATEMENT BY THE BOILER ENGINEERING CO., 931 FEDERAL TRUST BLDG., NEWARK, N. J.

Cross baffling of horizontal water tube boilers has proved to be so successful and, in general, so superior to parallel baffling that the same principles are now being applied to all bent tube types of boilers. Fig. 50 to 53 inclusive show installations of cross baffling applied to bent tube boilers.

In most instances it is possible to cause the first bank of tubes to absorb considerable radiant heat. The employment of high gas velocities through the first bank is discouraged. Ample furnace volume and low gas velocity in the early stages of flow through the boiler give a higher resultant boiler efficiency, and the elimination, in most cases, of slagging troubles. In many instances it is desirable to place the first baffle as many tubes away from the fire as possible. This reduces gas velocity and increases absorption of radiant heat.

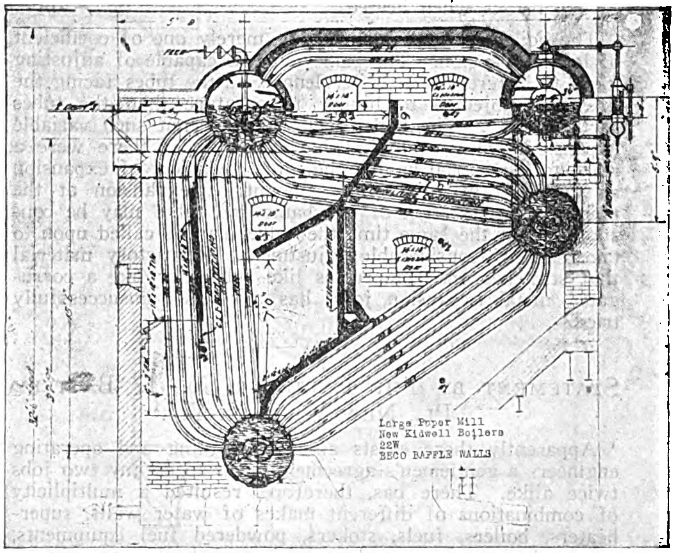

FIG. 52—NOVEL BAFFLING OF A KIDWELL BOILER, BOILER ENGINEERING CO.

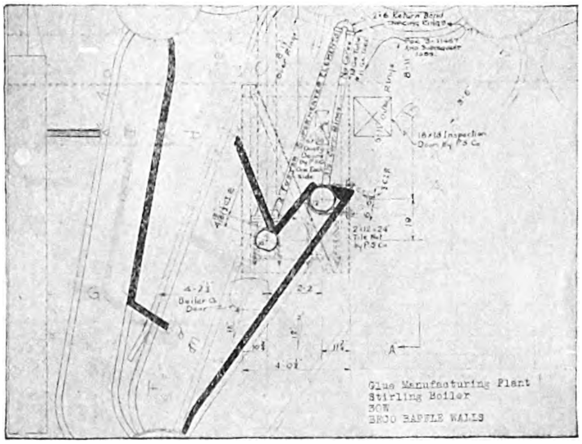

FIG. 53—BECO BAFFLED STIRLING BOILER, BOILER ENGINEERING CO.

An unusual method of baffling a Stirling boiler is shown in Fig. 53. In some installations the baffle has been built straight through the superheater instead of using the roundabout construction shown.

It has been found that reinforcing rods may be used where temperature variations are not great, as in curtain walls. Rods must not be used where there is considerable change in temperature. Corrugated sheet metal separators, 0.0126 in. thick, are inserted through the diagonal alleys. They may disintegrate and corrode without harming the wall in the least and without permitting leakage. The corrugations keep the sections of plastic in place, prevent gas leakage and provide positive expansion joints for preventing cracking.

The following paragraph, from page 5 of the University of Illinois bulletin, on "Thermal Expansion of Fire Clay Bricks," explains why difficulty is experienced in trying to unite steel and plastics where temperature variation is great:

> "It is of particular scientific interest because, as will be shown later, different brands of fire-clay brick expand to different degrees when heated; the expansions are seldom proportional to the increase in temperature, but are subject to very marked and characteristic irregularities; and silica and its various allotropic modifications, which are present in varying concentrations in fire-clay bricks, have very high and irregular, but characteristic, expansions when heated."

The boiler baffle problem is not merely one of coefficient of local expansion. The baffle must be capable of adjusting itself to differences in boiler length, as the tubes facing the fire are subjected to higher temperature than the tubes farther away. The boiler baffle must permit such variable expansion. This could not be done even if there were a refractory material having the same coefficient of expansion as the tube material. The amount of expansion at the points of intersection of the baffle and tubes may be constant, yet at the same time the baffle may be called upon to take care of considerable adjustment. Refractory material that stretches and compresses like rubber or like a corrugated metal expansion joint has also been unsuccessfully tried.

STATEMENT BY THE ENGINEER CO., 17 BATTERY PL., NEW YORK, N. Y.

Apparently there exists among designing and operating engineers a gentlemen's agreement never to do any two jobs twice alike. There has, therefore, resulted a multiplicity of combinations of different makes of water walls, superheaters, boilers, fuels, stokers, powdered fuel equipments, fans and air preheaters that makes each baffle an engineering study and delays the collection of comparable data. Now that experience in application has been gained, the cross baffle may be depended upon to reduce the draft loss through the boiler from 33 to 50 per cent of that obtained at the same ratings with longitudinal baffles. Higher boiler ratings with the same draft at the damper have invariably been obtained and the load on induced draft fans materially reduced; 50 per cent additional rating is usually obtained.

While reduction in flue gas temperatures has not invariably followed the change to cross baffles, it is the general rule; the amount depends, in a measure, on whether the tile baffles originally used leaked badly or only the usual amount. Enco baffles are gas tight so that the reduction is due in part to this fact as well as to design.

On two new 5000 sq. ft. boilers, Fig. 54, which were similar in every respect except the baffling, the draft loss at 300 per cent (10 k-B.t.u. per sq. ft. per hr.) rating was 50 per cent lower and the flue gas temperature was 35 to 40 deg. fahr. lower on the Enco baffled boiler.

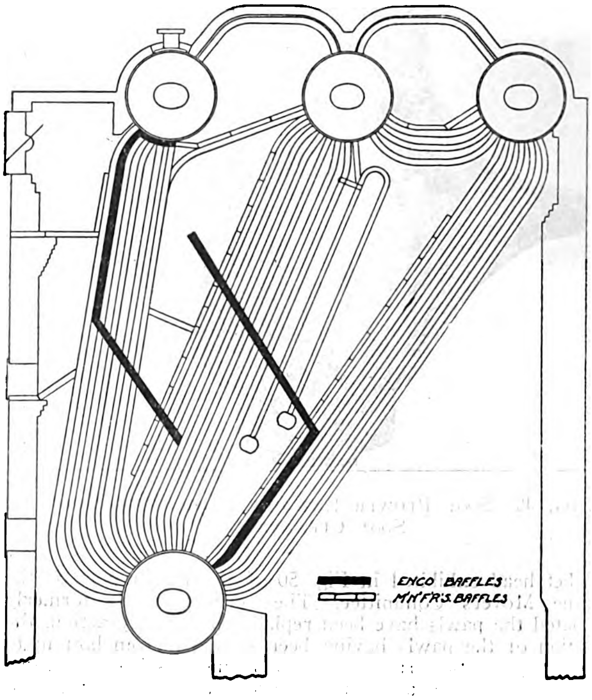

FIG. 54—STIRLING BOILER SHOWING CROSS BAFFLES AND CORRESPONDING LONGITUDINAL BAFFLES, THE ENGINEER CO.

Dryer steam has been the rule as the hot gases sweeping across the upper ends of both the front and second tube banks aid the release of the steam as they do along the front header of the horizontal water tube boiler. The steam generation is divided more evenly between these two tube banks, instead of concentrating it, as usual, in the first two rows of the front bank (as shown by scale deposit), and cuts down the "geyser action" and "squirrel caging" in the upper drums at high rating. The dryer steam naturally helps the superheaters by making the separation of water from the steam easier. Superheat is usually raised from 10 to 20 per cent by the cross flow, the results resembling those obtained with the interdeck superheater in the B. & W. boiler.

Notable betterment of furnace conditions at high ratings has been noticed as the gases move quickly and easily out of the furnace into the first pass, reducing the furnace temperature, preventing stoker and wall troubles, steadying combustion, and cutting down slagging on furnace floors and tube surfaces. Cleanliness of heating surface is more easily maintained as the gas flows at a substantially uniform velocity through the first and second passes carrying the ash and soot in suspension until the bottom of the third pass is reached, where the suspended matter is dropped behind the mud drum.

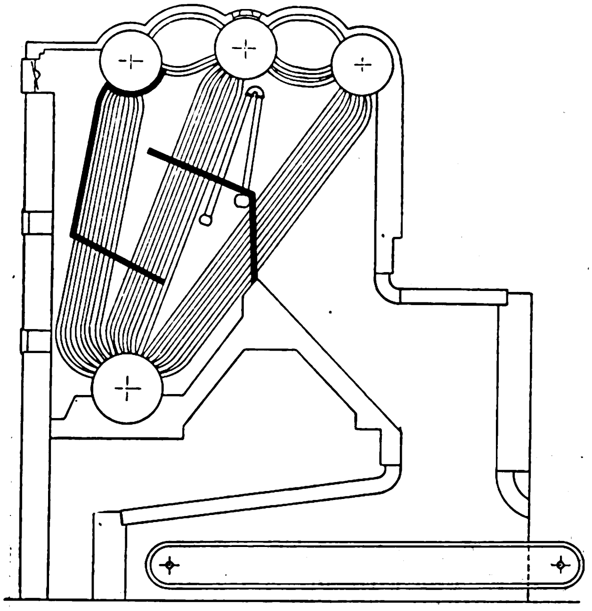

FIG. 55—CHAIN GRATE FIRED STIRLING BOILER SHOWING CROSS BAFFLES IN CONJUNCTION WITH REAR ARCH, THE ENGINEER CO.

In cooperation with one of the arch companies, the Enco cross baffle has been combined with the new back arch construction, Fig. 55, over chain grate stokers burning anthracite coal. An installation at a Pennsylvania public utility plant has given satisfactory results as to increased capacity, fuel economy, cost of maintenance, low ash pit losses, and absence of secondary combustion.

FEED WATER REGULATORS

STATEMENT BY NORTHERN EQUIPMENT CO., ERIE, PA.

Those engineers who have thoroughly studied feed water regulation now recognize that many of the difficulties which have heretofore been attributed to feed water regulators are really due to other causes which the feed water regulator is attempting to correct. For example, variations in excess pressure are really problems of pump discharge pressure control. Changes in feed water temperature which cause violent surges are really heater problems. The change of load from one boiler to another is really a furnace problem. Recognizing all this, a new line of sylphon type equipment has been developed which overcomes many of these external difficulties.

Type SS Differential Pressure Regulating Valve

The new Copes Type SS differential water pressure regulating valve is an important development. This valve, Fig. 56, is designed for use in connection with any type of feed water regulator, and can be installed in either horizontal or vertical feed lines. Valve "A" controls the line from the inlet side of the Type SS valve. "B" is the line to the discharge side of the regulator valve. Sylphon bellows "C," made of 4-ply brass, actuate the control valve "F." The outside of this bellows is subjected to the water pressure at the inlet of the feed water regulator valve; the inside is subjected to the water pressure on the discharge side of the feed water regulator valve. It is subjected only to the differential water pressure, but will withstand an unbalanced pressure of more than 400 lb. per sq. in. It is unaffected by feed water temperatures of 600 deg. fahr., and has, by actual test, stood 93,000,000 reversals without failure.

The effectiveness of the Type SS valve is shown in Fig. 57. The data were taken during a 2-hr. test at the Saginaw River Steam Station of the Consumers Power Company, Zilwaukee, Mich. During the first hour the boiler was held at fairly uniform load, but during the second hour the load varied greatly. At one time when the air was shut off completely the load dropped from 128,000 to 65,000 lb. per hr. within two minutes. Two minutes later the air pressure was back to 120, and the load back to normal. Despite these severe operating conditions, the Type SS valve held the excess pressure within limits of 5 lb.

Type RG Feed Flow-Water Pressure Regulator

The Copes Type RG combined feed flow-water pressure regulator, Fig. 58, combines the differential water pressure regulating valve and the feed water regulator control valve in one compact unit which can be installed in either horizontal or vertical feed line. With a constant load on the boiler, there is a constant opening at valve "C," and no movement of valve "D" or the bellows. Increase or decrease in feed water header pressure is regulated by the bellows and valve "D" to maintain the desired differential. Fig. 59 shows the results obtained in a central station with the Type RG regulator. The steam output fluctuated 28,000 lb. per hr. and the pump pressure showed a variation of up to 55 lb. The excess pressure, as controlled by the Type RG regulator, varied within limits of 5 lb.

Type DS Governor

A new, improved Type DS pump governor, shown in Fig. 60, has been developed. As a first step in designing it, tests were made to compare the action of springs with weighted levers. The spring was abandoned because it de-

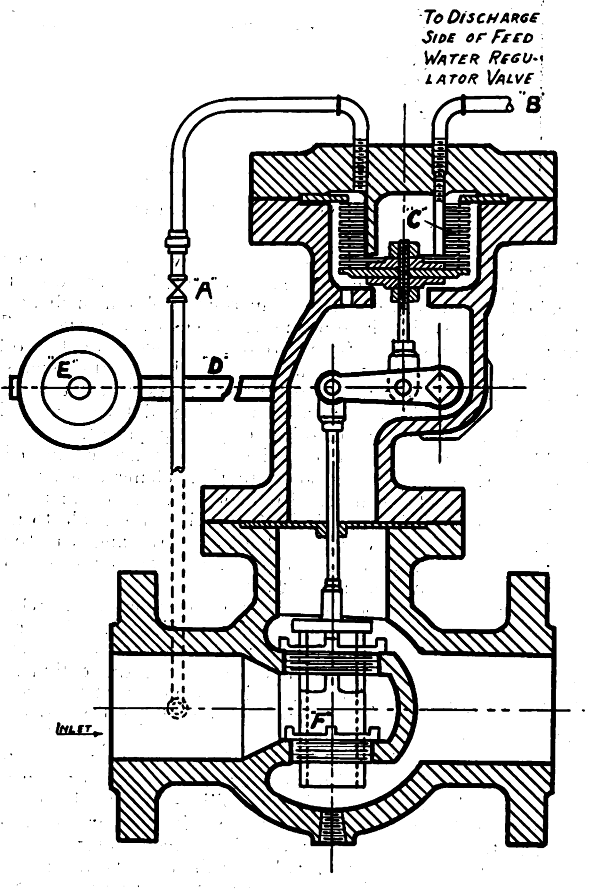

FIG. 56—TYPE SS DIFFERENTIAL PRESSURE REGULATING VALVE, NORTHERN EQUIPMENT CO.

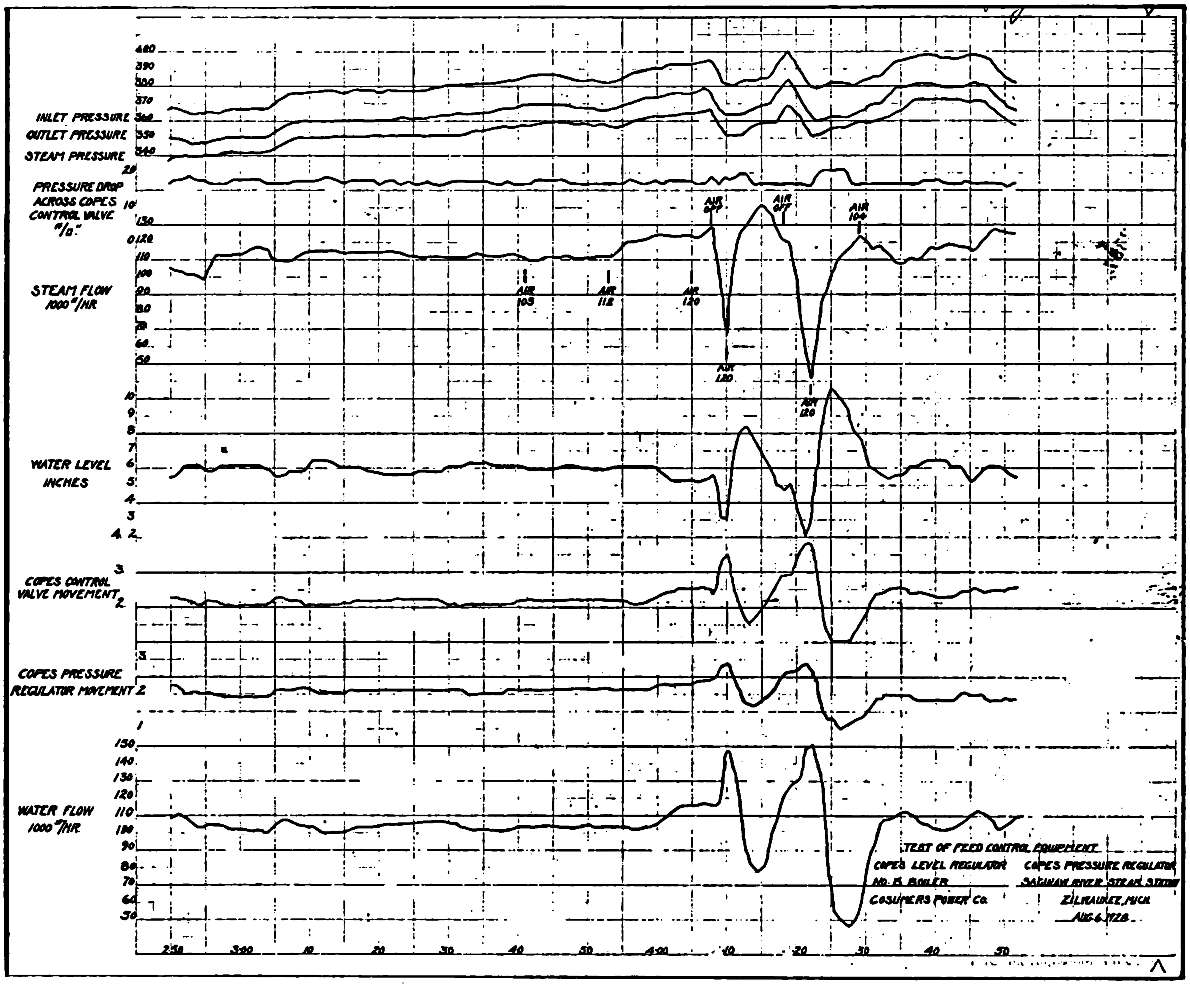

FIG. 57—TEST OF TYPE SS VALVE AT ZILWAUKEE, NORTHERN EQUIPMENT CO.

teriorated quickly, and, even when new, was less accurate than the weighted lever. The weighted lever was then studied in comparison with a mercury column such as has replaced the spring in some newer types of governors. The mercury column was found to be very accurate, but other weaknesses offset its accuracy, and the height makes it rather unwieldy for many installations. As a result of these tests it was decided to retain the weighted lever which has proved so satisfactory in other Copes equipment.

All these things were of minor importance compared to the necessity of having an actuating element which was both strong and sensitive. In theory, a diaphragm is ideal, but in practice it is not. It is practically impossible to make a diaphragm which combines both strength and sensitivity; nor will a diaphragm withstand high steam or water temperatures for any length of time.

For many years the Copes pump governor had a cylinder and piston in place of a diaphragm. This gave better all-around service over a period of years than any other actuating element used up until that time. But the cylinder required oiling. It is on the actuating element that the greatest advances have been made in the new Type DS governor. The actuating element, a brass sylphon bellows, is both strong and sensitive. It is unaffected by high steam or water temperatures, and will withstand an unbalanced pressure of more than 400 lb. It requires no oiling—practically no care of any kind. A horizontal lever shaft, similar to the one used in the control valve of the Copes feed water regulator, replaces the sliding stem valve ordinarily used. This reduces friction to a minimum, and does away with the danger of dirt being carried into the stuffing box. It can also be made much larger, thus increasing the ruggedness of the governor without affecting the balance.

The new Type DS governor is designed for installation on reciprocating, turbine or motor-driven centrifugal pumps. It is suited for differential excess pressure service for boiler feeding, constant pressure service, differential reducing valve service on motor-driven centrifugal pumps, and relief valve service on belt or gear-driven pumps.

All Copes valves, including the SS, RG and DS types for working steam pressures of more than 250 lb., are equipped with outboard ball bearings as mentioned in the 1928 report. For pressures of 1200 lb. and over, the hydraulic relay operated control valve, mentioned briefly in the 1928 report, has been tested thoroughly. The hydraulically-operated valves have operated successfully with water pressure differentials of as high as 500 lb., far higher than that normally found in central stations where the working steam pressure is from 400 to 600 lb.

Type RGF Regulator

In the 1928 report the Type L regulator, controlled by a combination of steam flow and water level movement, was described. The ideas behind this type of regulator have been carried still further by the development of the Type RGF regulator, to feed in proportion to steam flow. Thus the overloading of the boiler with water during periods of light loads, encountered with regulators actuated only by changes in water level, is eliminated.

The unit consists of the Type RGF valve, shown in Fig. 61, and the Type R thermostat designed for high-pressure

service. The thermostat is influenced by water level to maintain fixed, safe limits of level. It functions primarily below normal load conditions in bringing boilers up to pressure and preserves a balance on the water input as influenced by variations in steam flow.

The steam flow unit consists of the lower sylphon bellows and bonnet with leverage, and is actuated by the difference in pressure between the regulator outlet and the superheater outlet, or the drop in pressure through the boiler and superheater. The inside of the steam flow bellows is subjected to the regulator discharge pressure which is common to both upper and lower sylphon bellows. The outside of the steam flow bellows is subjected to the superheater discharge pressure. As steam flow increases, the pressure on the discharge side of the regulator and on the inside of both bellows increases proportionately. Under such conditions, the superheater outlet pressure remains practically constant. Therefore, the steam flow bellows have an expanding movement which is transmitted through the levers and strut "H" to the pressure regulating valve "D," giving it a greater opening and thus increasing the differential. As steam flow decreases, the steam flow sylphon bellows contracts and the reverse action of the levers and valve "D" decreases the excess. The design of the leverage is such that it is possible to get a rise in differential equal to the drop through the boiler and superheater. In cases where the drop through the boiler drum and superheater is not sufficient to attain the desired rise in differential, an orifice plate can be installed in the superheater outlet to obtain the desired results.

The Type RGF regulator is designed primarily for high-pressure units, as units operating at low pressures rarely, if ever, produce conditions requiring this type of equipment. Performance of this new regulator has been satisfactory.

The 1928 report also mentioned the tendency to increase the ratio of water storage and liberating surface to the evaporating surface in boilers. This is particularly true on large units operating at high rates of evaporation with wide variations in load. Several of the latest installations are designed with two or more drums. This is advantageous, as storage capacity is provided on light loads to meet peak load requirements. The Copes regulator, feeding continuously, will vary the water level within fixed limits, thereby giving a feed input to meet this water storage requirement.

STATEMENT BY SMOOT ENGINEERING CORPORATION, 136 LIBERTY ST., NEW YORK, N. Y.

Boiler Feed Water Regulation

At low ratings, boiler water level tends to increase rapidly with rating increases. This ratio decreases as the ratings go to higher values, due to the greater velocity of water circulation. This relationship, commonly called "swelling effect," is greater for a given load change when steaming at 200 per cent (6.7 k-B.t.u. per sq. ft. per hr.) than when operating at 300 per cent (10 k-B.t.u. per sq. ft. per hr.) rating.

Where a regulator is set for constant level, it must constantly oppose the natural tendency of the water to change immediately its level with every shift in load. Thus, if the load suddenly drops a little, the natural "shrinking effect" of the water will immediately cause the water level to drop, which causes the feed valve to open on a constant level regulator. This increased water feed tends immediately to reduce further the steaming rate with a resulting additional decrease in water level. This double effect compounded against the constant level regulator is decidedly unstabilizing. To overcome this requires either considerable inherent stability in the regulator or an extremely slow, or unresponsive, regulating device in order that continued oscillations or hunting will not prevail.

Quite opposite to the above is the stabilizing reaction obtained in a feed water regulator by causing a function of the boiler rating to reset the level mechanism to a new value, increasing or decreasing it in proportion to the changed steaming rate of the boiler. If the full extent of this relationship were used (adjusting the regulator to compensate for the entire "swelling effect" of the water), then very little stabilizing action would be needed, because there would be no artificial reactions to correct for, inasmuch as the natural tendency of the water level to shift with load would equal the level produced by the regulator. Under such conditions the regulator on sudden load changes would not have to move immediately, but would only have to adjust the water feed valves to maintain the constant ratio of steam flow to water flow without any interference from the "swelling effect" of the water. The net result at all steaming rates would be to obtain by regulation a constant weight of water in the boiler and not a constant level of water in the boiler drums.

In modern boilers with large water wall areas, the drum capacity in proportion to the tube capacity has been reduced in some cases to a point where the "swelling effect" of the water from zero rating to maximum rating is greater in inches of water than the height of water glass provided. From this it may be concluded that from a safety standpoint it would be better to operate with considerably higher water at high loads than at low loads. As a typical example of common practice, take a large boiler with a 24-in. water glass. The "swelling effect" in this boiler would likely be 20 in. from minimum to maximum load. This means that if the boiler were steaming at its full load, with the water in the middle of the gage glass, and the load were suddenly lost, the water would go down and out of sight by 8 in. The reverse would be true if steaming at a low rate with water in the mid-position, in which case the sudden increase in load to full value would put the water over the top and cause priming.

If instead of carrying the water at a constant mid-position level it had been regulated automatically at full load near the top, then the sudden full drop in load would still have left the water in sight by 4 in. From this, the conclusion can be drawn that not only is a gradually increasing water level desirable from a regulating point of view, but is also safer from an operating standpoint. To obtain this result in a feed water regulator requires an auxiliary loading force, foreign to the regulator itself, which bears some definite relationship to boiler rating. The conventional type of feed water regulator uses some form of fixed characteristic to assist in obtaining stability, whose purpose is to change the control value of the regulator so that the water level is definitely regulated at a lower level at high load than at low load. This characteristic is similar to that inherent in all types of speed governors for controlling engines, turbines or other devices where a large time lag, capacity or inertia is encountered in the regulated response.

In every case, some movement of the regulating device is used to react on the control balance and, in the case of a feed water regulator, to give a progressive reduction in the level setting in proportion to the opening of the feed valve. This action is stabilizing, but if its sense of motion were reversed, then its reaction on the regulator would be very unstable, resulting in continuous hunting.

To obtain the desirable characteristics outlined for increasing water level with rating, it is necessary to use a suitable loading force or pressure, which is a measure of the boiler load and preferably one which follows the same law that governs the "swelling effect" of water in the drums and tubes.

The differential pressure from the boiler drum to the mud drum when plotted against rating, follows the same type of curve as does the water level corresponding to quick rating changes, previously referred to as "swelling effect." Hence, this differential may safely be used to load or adjust a sensitive water level control device inasmuch as it is of sufficiently large magnitude to be of practical use.

Another force equally as positive, and always bearing an exact relationship to rating, is the superheater differential. While this differential varies as the rating squared, it may, nevertheless, be used as a suitable variable loading. Its value is much larger, being measured in pounds where the corresponding mud drum differential is measured in inches of water.

The water level regulator to which these forces have been applied consists of a newly developed control element designed to work in conjunction with a standard Smoot regulator, power cylinder, and stabilizing device. The control element consists of two closed chambers of equal size cast together, and whose bottoms are connected with a free passage. They are partially filled with mercury which, when the casting is tipped, is free to flow from one chamber to the other. The casting is hung on rugged knife edges, centrally located between the two chambers, and the unit is statically balanced with the mercury in place. Pressure connections are taken from the top of each chamber through flexible steel tubing, terminating in a stationary block for suitable piping connections. At the end of one of the chambers, a connecting rod transmits any movement of the chamber casting to a weigh beam, which in turn actuates the regulator power mechanism.

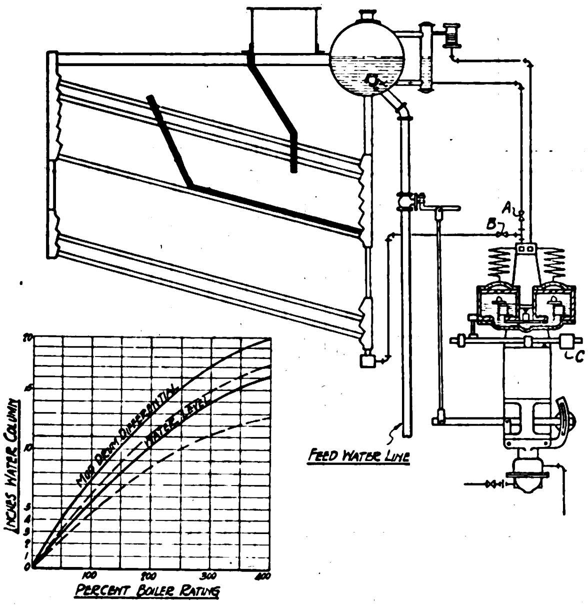

FIG. 62—FEED WATER CONTROL BASED ON MUD DRUM PRESSURE, SMOOT ENGINEERING CORP.

As shown in the diagram, Fig. 62, one of the chambers is piped to a constant level tank, the steam side of which leads to the top, or steam end, of the boiler drum water column. The other chamber connects to the water or bottom end of the water column and thus the two chambers act as a large "U" tube measuring in inches of mercury the differential in water level from the constant level tank to the water level in the boiler drum. Hence, a difference in weight of mercury from one chamber to the other will vary directly with the head of water in the boiler, and this difference in weight is used as a control force to actuate the regulator movement. The weight of mercury is balanced against the weight on the weigh beam. Shifting from one chamber to another in response to changes in water level, the weight of mercury will cause the regulator to respond, giving a controlled water level of constant value. Suitable stop valves of the float needle valve type are provided in each chamber to prevent loss of mercury in the event an excessively high differential is accidentally encountered. One of the outstanding features of this device is the absence of friction in the moving parts as no packings or pressure tight bearings are used. This permits sensitiveness; the degree is not affected in any way by the amount of boiler pressure, as is the case in the diaphragm type of control. This is an important feature when considering the pressures used in modern boilers.

Fig. 62 shows the application of this regulator to a boiler, together with the necessary connections to obtain graduated increasing level with rating when actuated by the mud drum pressure. The two curves show actual test results on a 600 sq. ft. cross-drum Springfield boiler burning powdered fuel. With valve A open and valve B closed, the regulator would control for constant level of water, the level being adjusted by the amount of weight C. With valve B slightly open and valve A open, there would be a flow of water through the valves toward the more negative pressure at the mud drum. As this flow increases, the pressure on the left-hand pressure chamber becomes more negative, causing the regulator feed valve to open and restore the pressure balance in the chambers to its former weight balance. This is accomplished, but in so doing, the water in the drum must necessarily be higher because of the pressure drop due to flow from the regulator chamber to the bottom of the water column through valve A. By adjusting the relative openings of valve A to B, a gradual variation in the magnitude of the opening force and its effect on the water level with rating changes may be had. The effect of such adjustment is illustrated by the dotted curves in Fig. 62.

Fig. 63 shows graphically the difference between water level control based on the ordinary position-level stabilizing characteristic, as shown by curve "B," and control using the new Smoot method above described and illustrated by curve "A."

Starting at light load on curve "A," a given sudden rating change "C" would cause the water level to rise along the dot-and-dash line to approximately 11½ in., and if the rating be then maintained at the full increased value, the water level, due to the regulator action, would check back to the base curve "A" at 10 in.

If the rating is then suddenly reduced by like amount "C," the level would immediately fall to about 4½ in., and then gradually return to the starting point of 6 in. on the base curve "A."

The total maximum water level swing due to the sudden up and down rating change "C" would be the value "a," while if an exactly like load change be traced out on the dotted lines, starting and finishing from the conventional base line "B," the resulting maximum level change would be the value "b," which is nearly double the value "a."

With both methods the sudden swelling effect must be the same. However, with the Smoot method, using a lower level at low load than at high load, the drum capacity for water storage would be used to its full value.

When sudden load changes occur, any given boiler drum capacity in effect is increased over the corresponding effective capacity when the usual method of holding a high level of water at light load and a low level of water at heavy load, is used.

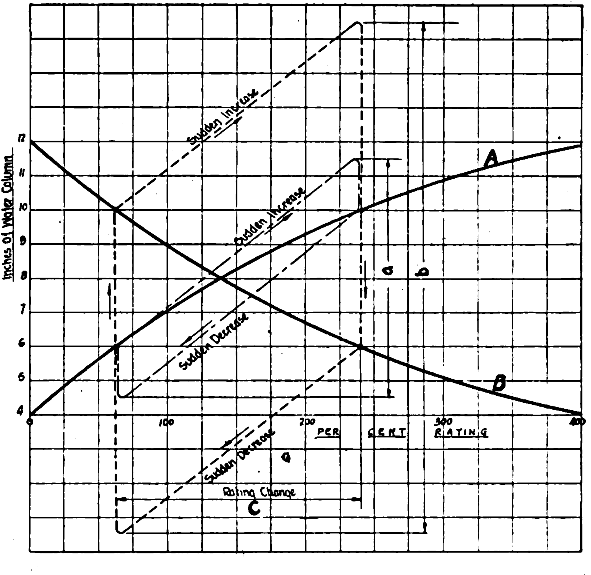

FIG. 63—COMPARATIVE CURVES SHOWING SMOOT WATER LEVEL CONTROL AND ORDINARY LEVEL REGULATION, SMOOT ENGINEERING CORP.

Fig. 64 shows an installation of a regulator of the type described above.

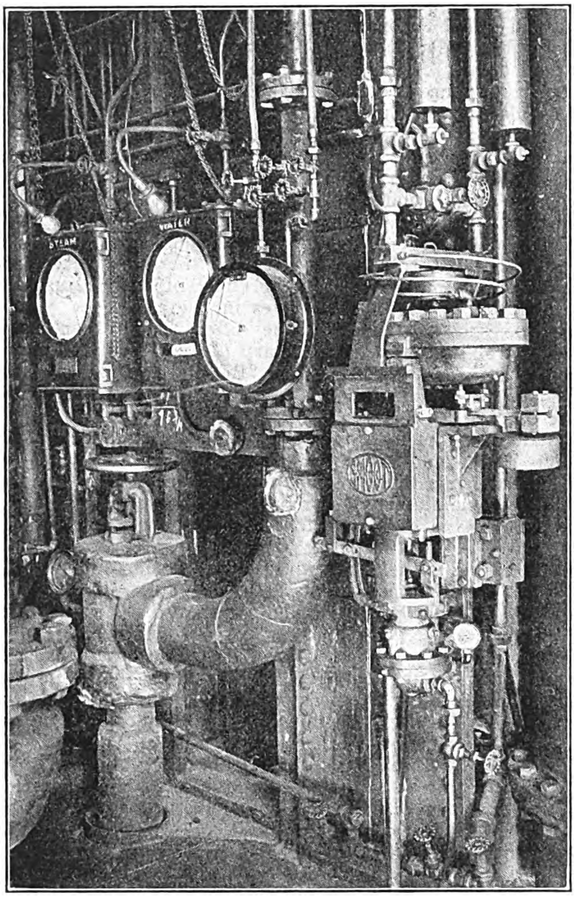

FIG. 64—Feed Water Regulator, Smoot Engineering Corp.

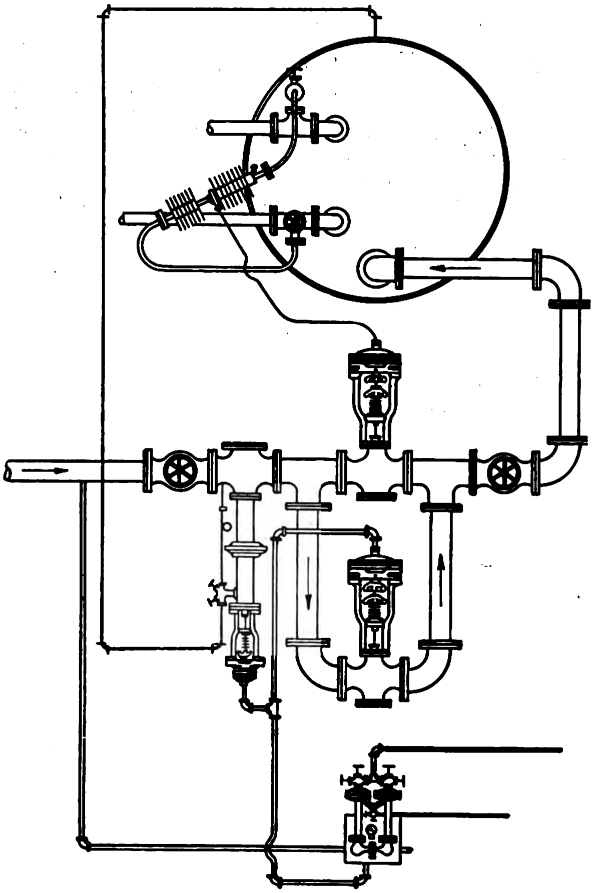

FIG. 65—Water Level and Steam-Flow Feed Water Regulator, The Swartwout Co.

STATEMENT BY THE SWARTWOUT CO., CLEVELAND, OHIO

The feed water regulator has been improved by employing a restricted disk that gives a gradual opening particularly at low ratings, together with a new design of diaphragm that will allow the long travel necessary to secure full opening of the restricted disk. This provides much closer regulation and tends to prevent the hunting action that sometimes occurs in high rating boilers.

Combination Water Level and Steam Flow Regulators

High rating boilers which are subject to sudden load changes are very difficult to regulate from the water line, because a sudden increase in load is accompanied usually by a rise in the water level which closes off the regulators. Thus the boiler is deprived of water at a time when it is needed. Also, when the load is suddenly dropped, the water level drops and the regulators open wide, thereby feeding more water than the boiler is evaporating.

To handle this situation, the Swartwout Co. has developed the system shown in Fig. 65. It consists of a standard regulator operated from the water line, an auxiliary regulator operated from the steam flow and a variable pressure differential valve also operated from the steam flow. These last two valves are controlled by a differential pressure Master Control connected to the inlet and outlet of the superheater. As the rating increases, the pressure drop across the superheater increases. This pressure drop actuates the Master Control and opens the auxiliary regulator, at the same time increasing the differential pressure, both in proportion to the steam flow. The capacity of this auxiliary regulator will be below the boiler capacity so that the water level will gradually drop until the water level regulator comes into action and maintains it at the proper level.

When the load decreases, the auxiliary valve closes and the differential pressure is reduced so that when the drop in boiler water level occurs, even if the main regulator should open wide, the differential pressure will be so low that an excess amount of water will not be fed.

Economizer Protection

To protect the economizer from excess water pressure, the Swartwout Company has developed an excess pressure

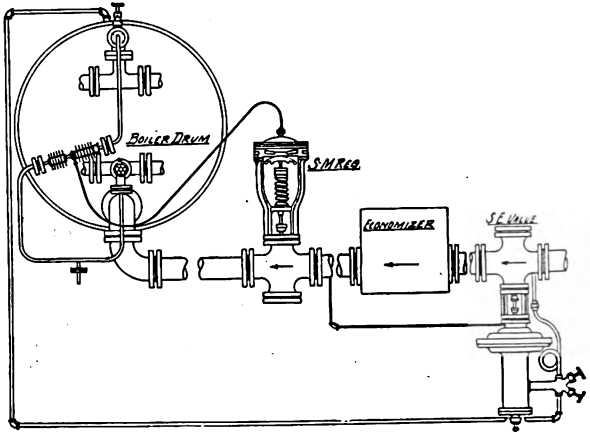

FIG. 66—Excess Pressure Regulator for Economizer Protection, The Swartwout Co.

valve, to be installed ahead of the economizer, that will pass just enough pressure to maintain the required pressure drop across the regulator. This is known as the Type S-E Valve and is illustrated in Fig. 66. The variable excess feature may also be applied to this valve as well as to the steam flow control.

WATER COLUMNS AND WATER GAGES

STATEMENT BY THE BABCOCK & WILCOX CO., 85 LIBERTY ST., NEW YORK, N. Y.

High-Pressure Water Gages

As pressures increased, experience indicated that satisfactory service could not be obtained from tubular water gage glasses, and that with boilers operating at pressures over 350 lb., the life of such glasses was from but a few hours to six weeks.

Pure feed water at a pressure of 350 lb. and upward has a chemical action on the glass, and even were the strength unimpaired, it is quite difficult to avoid breaking the glasses when packing them for pressures of 600 lb. and upward. Flat, plain or fluted gage glasses are better for such high pressures, but deterioration from the action of the water and difficulty in packing render them unsatisfactory.

Double flat glass protected on the water side by mica was then tried successfully under pressures up to about 600 lb., but with higher pressures it was impracticable to pack the glass steam-tight without breaking it.

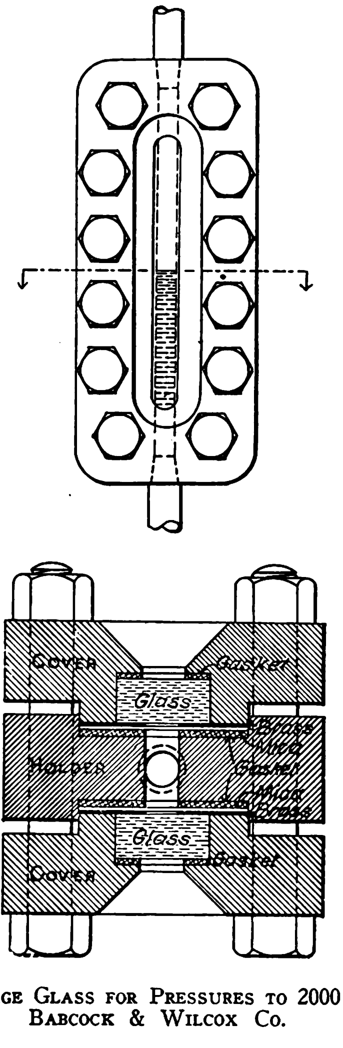

FIG. 67—GAGE GLASS FOR PRESSURES TO 2000 LB., THE BABCOCK & WILCOX CO.

To meet these high-temperature conditions the fitting illustrated in Fig. 67 was developed, which has given satisfactory service under pressures up to 2000 lb., the highest under which it has been tested.

The body comprises a central holder and two covers, each slotted vertically. In the recess in each face of the holder is first placed a gasket, then a sheet of mica and on that a thin brass gasket. In the recess of each cover is placed first a gasket and then a bar of glass about 0.7 in. thick. When the parts are bolted together only the boiler pressure can come on the glass, which is protected from chemical action by the mica. The thin brass gasket seals the edge of the joint between the cover and the glass. In service the glass lasts indefinitely, but the gaskets and mica need renewal in four to six weeks. Two fittings at different elevations are used on the same column when considerable differences in water levels must be indicated.

STATEMENT BY THE NATIONAL CO., INC., MALDEN, MASS.

Flat Gage Glass Illuminators

The present trend toward higher boiler pressures has resulted in the widespread use of the flat type gage glass in order to withstand pressures of 400 lb. and over. The general type of gage consists of a thick glass plate on either side of the gage, held in place by steel face-plates and gasketed with mica.

The illumination of this type of gage depends upon several factors: thickness of glass, collection of dirt and rust by mica gasket, distance of gage from operator, angle of visibility of gage from operating floor, elimination of reflected light from glass surface, establishing a distinct meniscus, amount of rust carried by water, and intensity of illumination.

This company has achieved success in the illumination of this type of gage by using the principle of reflecting light from the meniscus or water level down to the operator. In the Type "D" illuminator, Fig. 68, light is directed upward at such an angle that the light will penetrate the glass and water. That portion of light which strikes the meniscus is reflected down at a similar angle, so that again it penetrates the water and glass and emerges into the air, continuing down to the operator. Other light which does not strike the meniscus continues upward and is dissipated. The result is a bright spot at the meniscus in distinct contrast to the remainder of the gage, which is dark. If the direction of light is at too sharp an angle to the glass, very little light penetrates the glass, and then after reflection very little light emerges. Again, if a light source is placed near the bottom of the gage glass, but no provision made for directing light upward, the result is a lighting up of the bottom part of the glass decreasing to darkness at the upper part of the glass. This gives a contrast between meniscus and glass in the upper portion, but if the water level is low there is no contrast between meniscus and glass in the lower portion. In the Type "D" illuminator, a hood is used to help direct light upward and to confine stray light.

A recent development in flat type gage illumination is the louvre type illuminator, Fig. 69. Using the same principle of reflecting light from the meniscus, this illuminator has several new features. A gain in intensity of light at the top of the gage is obtained by using a larger light bulb in conjunction with a chromium plated mirror of such shape that it directs light upward at the proper angle for penetration of the gage and reflection from meniscus to operator. Metal louvres set at this angle prevent stray light from striking the gage glass at improper angles. The result is a very strong contrast between the dark gage glass and the bright meniscus, regardless of water level. Several mechanical features of note are: the interchangeability of the light bulb so that it may be inserted either right or left hand; pivoting of the metal louvres so that an explosion automatically closes them, thus protecting the light, reflector and glass dust plate; incorporation of a glass dust plate

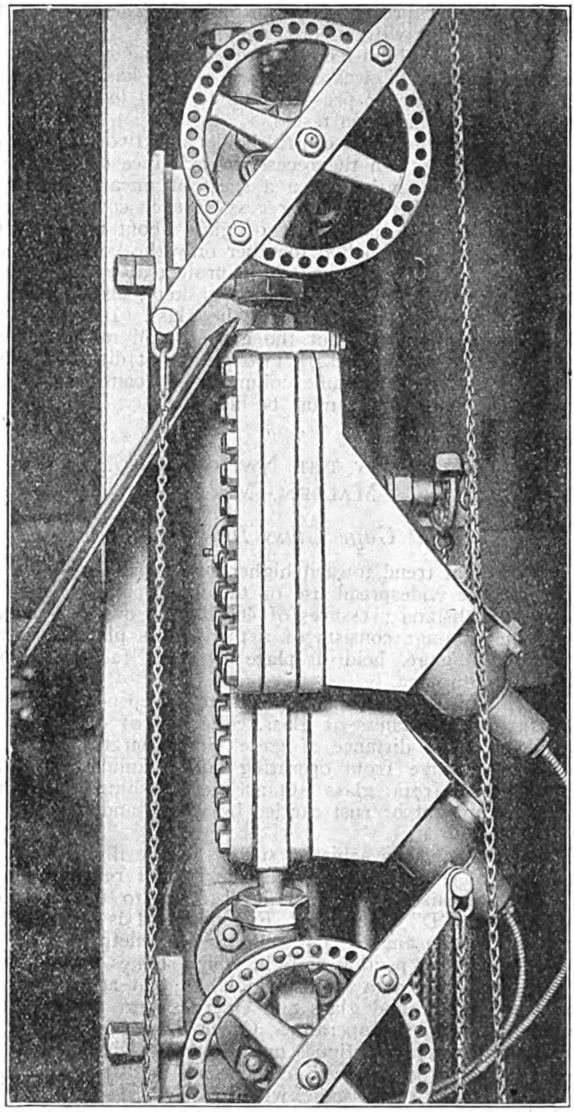

FIG. 68—TYPE D WATER GAGE ILLUMINATOR, NATIONAL CO., INC.

just beyond the louvres to seal the illuminator from dust; easy removal of the louvre unit for the occasional cleaning of the dust glass.

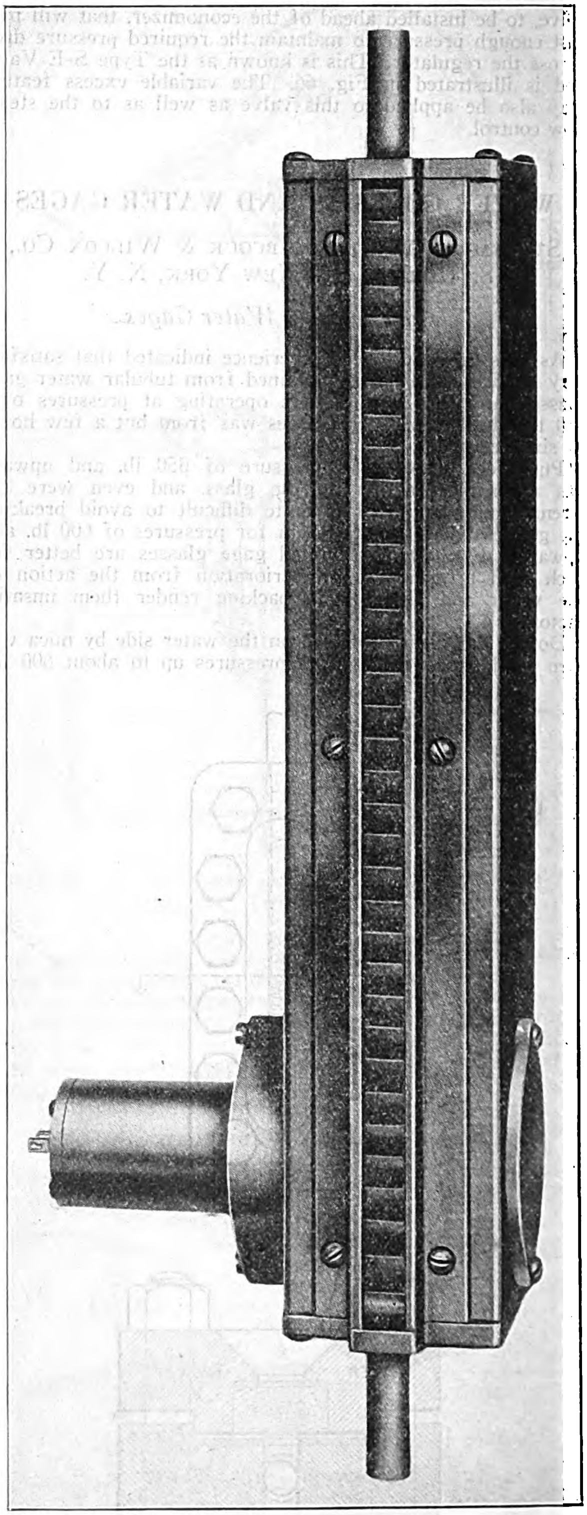

FIG. 69—LOUVRE TYPE WATER GAGE ILLUMINATOR, NATIONAL CO., INC.

STATEMENT BY THE RELIANCE GAUGE COLUMN CO., CLEVELAND, OHIO

Considerable development has been made in the manufacture of floats, although for several years they have ceased to be the limiting factor as regards pressure or temperature. Either the deposited nickel or the drawn monel floats are today the most dependable part of the water column. During the past year the use of copper floats has been discontinued, except on low-pressure work and a few odd sizes. Columns for pressures up to 250 lb. are now equipped with drawn monel metal floats, Fig. 70, reinforced at the center by a steel truss ring; the two sections are fused together on a special machine without the addition of any material. Monel floats stand 200 lb. higher pressure than copper floats of the same weight, are not affected by temperature, stand more abuse and have greatly increased reliability. They are also used in forged steel columns up to 450 lb. For forged steel columns up to 750 lb., a spherical deposited nickel float is used. These floats are regularly tested to 1200 lb.

The Reliance gage cock for pressures up to 450 lb. has been improved to its present design, Fig. 71. The use of a spring as the closing force has been completely justified, and since the adoption of the monel metal spring four years ago no spring failures can be reported. They are not af-

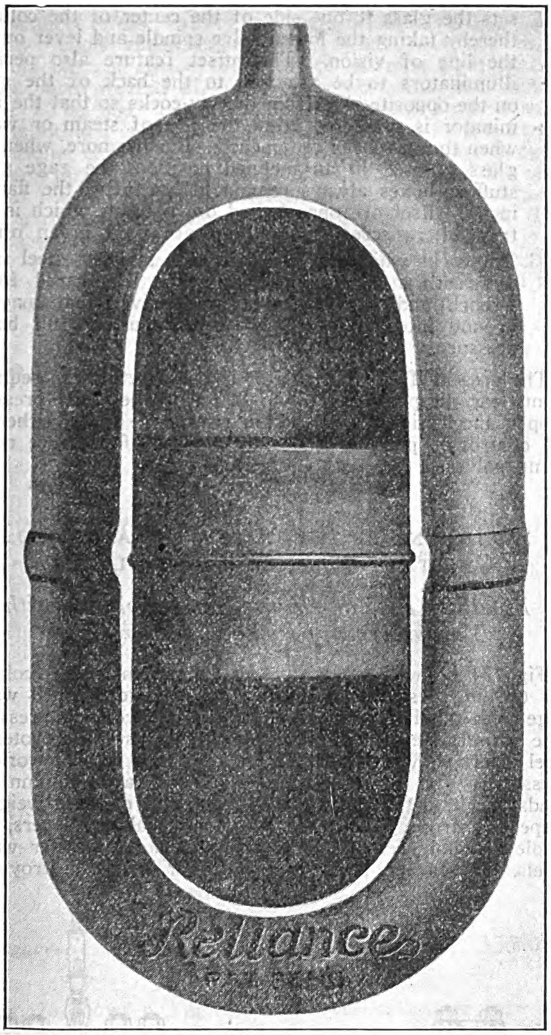

FIG. 70—DRAWN MONEL FLOAT FOR PRESSURES TO 250 LB. PER SQ. IN., THE RELIANCE GAUGE COLUMN CO.

fected by temperature, never corrode and do not lose strength. The new design has a renewable monel seat and a renewable chrome silicon cone valve disk. These parts are readily removed and so designed that the renewed parts are always installed in perfect alignment independent of the threaded portions. For pressures above 450 lb. the design shown in last year's report is used.

Fig. 72 shows the Reliance Tiltview water gage, which consists of a standard water gage with an adapter for inclining it. The adapter consists of bronze angle fittings; the extension piece at the top is a seamless tube which in the flanged type is welded to steel flanges. The horizontal column connections are readily accessible for cleaning by removing plugs.

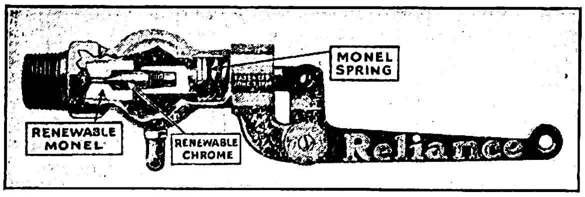

FIG. 71—GAGE COCK FOR PRESSURES TO 450 LB. PER SQ. IN., THE RELIANCE GAUGE COLUMN CO.

The upper and lower fittings are held in alignment by means of a steel tie plate, which also acts as a background to make reading of the level more easy. The alignment is perfected in the shop, and there are no adjustments to make or change at installation. These Tiltview gages are made for pressures up to 750 lb. with flat glasses; the tubular glasses only being recommended up to 400 lb.

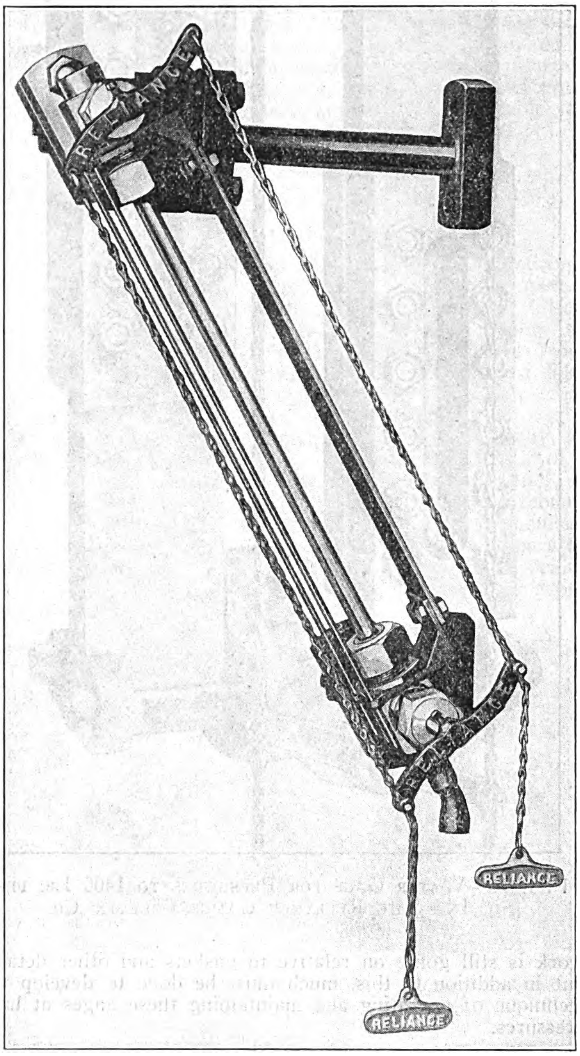

FIG. 72—TILTVIEW WATER GAGE FOR PRESSURES TO 400 LB. PER SQ. IN., THE RELIANCE GAUGE COLUMN CO.

Reliance has water columns equipped with gage cocks and water gages in operation up to 1400 lb. pressure. The water gage, Fig. 73, has flat glasses protected from the action of the steam and water by sheets of mica. Operation has developed certain requirements differing from ordinary water gages. The design must be heavy, so that there is no warping due to pressure, temperature or installation. The workmanship must be of a very high order. The design must be such that in case of replacement an entire glass housing can be removed and a spare put on. This permits careful assembly of the glass, mica and gaskets on a bench in a horizontal position. The assembly should then be steam-tested on the bench and the gaskets followed up when hot. This requires a high grade, careful mechanic, and even such a man cannot get uniform results unless the housing is removed from the column and proper facilities are provided to make a good assembly. Attempting to change a glass on the column is generally unsuccessful. Experimental

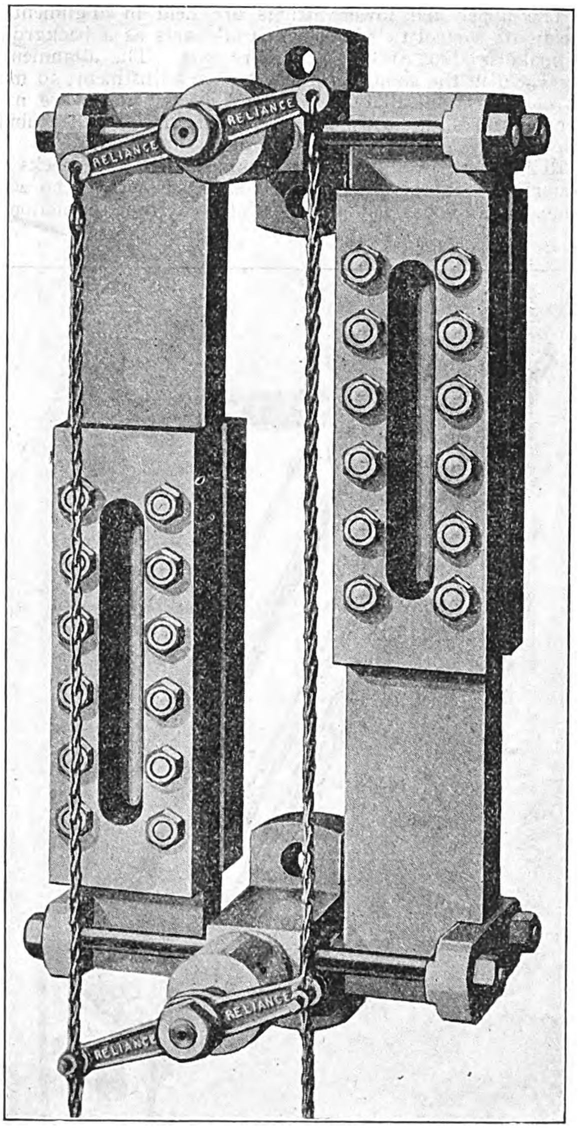

FIG. 73—WATER GAGE FOR PRESSURES TO 1400 LB. PER SQ. IN., THE RELIANCE GAUGE COLUMN CO.

work is still going on relative to gaskets and other details, but in addition to this, much must be done to develop the technique of operating and maintaining these gages at high pressures.

STATEMENT BY THE STETS CO., 141 MILK ST., BOSTON, MASS.

Experience with bronze water gage fittings and try-cocks since pressures of 300 lb. and over have come into use has shown conclusively that bronze is unsuitable for higher temperatures. The metal tends to become brittle, and the threads on the spindles and in the valve bodies break. The use of bronze or brass for water gage valves and try-cocks has been superseded by forged steel with stainless steel trim, either heat-treated or hardened by the Nitralloy Process. In addition to being a 100 per cent wrought and forged steel column, it has three outstanding features:

1. Open, water-filled, non-collapsible floats of large displacement and excess power for operating the whistle valve.
2. A bolted flanged offset in the water gage valves which sets the glass to one side of the center of the column, thereby taking the lower valve spindle and lever out of the line of vision. The offset feature also permits illuminators to be attached to the back of the glass on the opposite side from the try-cocks so that the illuminator is protected from the jets of steam or water when the try-cocks are opened. Furthermore, when the glass is used in an inclined position, the gage glass stuffing boxes always remain in line after the flanges in the offset are once bolted down tight, which is not true where screwed couplings are used in an offset.
3. Try-cocks which are provided with stainless steel spindles with a protruding end, which is squared for a wrench and slotted for a screwdriver that may be ground into the seat with column under full boiler pressure.

The present Type E regulator is still meeting the requirements for all pressures up to 800 lb., where the pressure drop is mechanically held within reasonable limits either by the control of pump speed or by the use of pressure regulating valves.

STATEMENT BY THE YARNALL-WARING CO., CHESTNUT HILL, PHILADELPHIA, PA.

Floatless Hi-Lo Alarm Water Column with Yarway-Sesure Inclined Water Gage

Fig. 74 shows a Yarway Hi-Lo alarm water column for 600 lb. pressure, with a Yarway-Sesure inclined water gage with tubular glass, good for 400 lb. working pressure. The same gage, when using the flat glass mica protected steel insert shown on the left, is good for 600 lb. working pressure. The Floatless Hi-Lo alarm water column depends for its action upon the displacement of solid weights, suspended from opposite ends of two balance levers, the whole assembly being in equilibrium at normal boiler water levels. Whenever high or low water levels destroy the

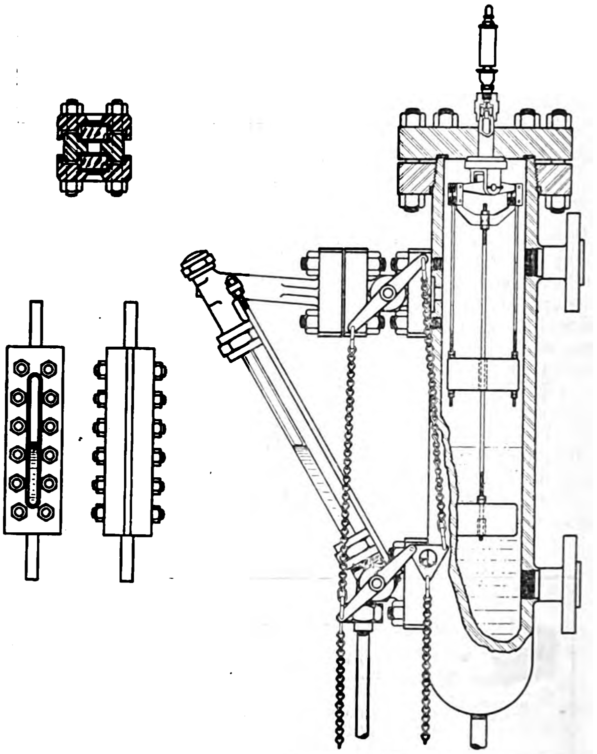

FIG. 74—WATER COLUMN FOR 600 LB. PRESSURE WITH TUBULAR GLASS FOR 400 LB. AND FLAT GLASS FOR 600 LB., YARNALL-WARING CO.

equilibrium of the weights, a rocking motion is imparted to the balance levers, causing a single whistle valve of extremely simple construction to be opened. If desired, a Mercoid electric switch connected to warning light or bell may be used instead of, or in connection with, the whistle alarm. The body of the column is forged from a solid steel billet, and is fitted with two forged steel flanges at the top. Boiler connections for the higher pressures are flanged, shoulder threaded and arc-welded. The studs for the support of the water gage are welded to the shell. The whistle valve parts are of stainless steel, hardened and ground. The tubular glass water gage shown attached to the column is of heavy bronze construction and is good for 400 lb. working boiler pressure; the same gage mountings with the steel flat glass mica protected insert are good for 600 lb.

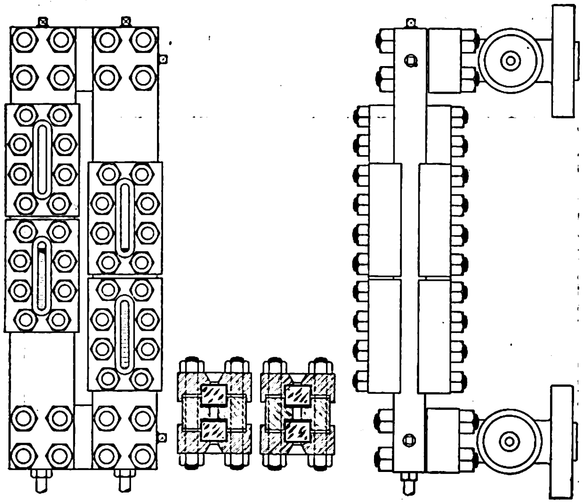

FIG. 75—YARWAY-SESURE GAGE FOR 1350 LB. PRESSURE, YARNALL-WARING CO.

Yarway-Sesure Vertical Water Gage for 1350 Lb. Pressure

Fig. 75 shows a Yarway-Sesure vertical water gage for 1350 lb. This gage is built of forged steel throughout; short flat ground glasses are used, with mica protected inner surfaces. The gage is arranged so that straight through vision is provided, which makes it possible to observe conveniently the water level. Because of the necessarily increased gasket pressure required to prevent leakage, it has been found advisable to shorten the length of the glass units. Four such glasses are shown, conveniently arranged on interchangeable water legs. Round boiler connecting flanges with 4 bolts are recommended for rigid support of these gages. This particular gage is of the vertical form, but can be built of the inclined form.

STEAM PURIFIERS

STATEMENT BY ANDREWS-BRADSHAW CO., DIVISION OF BLAW-KNOX CO., PITTSBURGH, PA.

One outstanding principle which has been determined to an even fuller extent than previously is that complete steam purification can be effected only by reducing the steam and entrained moisture velocity below that point at which atomization of the water particles takes place; i.e., re-entrainment in the steam stream must be prevented.

The outstanding development in the past year has been the adaptation of the Tracyfier principle to line use. In addition, the larger capacity drum-type Tracyfier has been developed and many installations made. The drum-type Tracyfier is put into the steam line at a predetermined point, exactly the same as a valve or separator. It can be placed directly above the boiler steam drum with outlet to superheater or to steam line, or it can be placed almost anywhere in the line. The drum-type Tracyfier carries the definite guarantee of the delivery of "Standard Specification Steam," which is defined as follows:

> "Steam shall be free from all solids, both soluble and insoluble. Samples of condensed steam shall not show more than nine parts total solids per million, which is the tolerance to cover dissolved copper and iron from the test condenser, unavoidable dust contamination during the collection of the sample and its evaporation, and unavoidable errors in the laboratory determination of total solids.
>
> "Steam shall be free from all moisture. Throttling calorimeter tests shall at all times show 100 per cent dry steam, plus or minus not more than two-tenths of 1 per cent, based on the determined normal of the calorimeter. The permitted variation of plus or minus two-tenths of 1 per cent is the tolerance for unavoidable variations in radiation and thermodynamic changes."

STATEMENT BY THE COCHRANE CORP., PHILADELPHIA, PA.

One of the installations of 1928 was the steam purifier installed on a Combustion Engineering Corp. steam generator at the Calumet Station of the Commonwealth Edison Co. The steam generator is fed with a good quality of feed water, the make-up being but 4 to 5 per cent from the Calumet River, the analysis approaching that of lake water. The steam generator operates at 325 lb. The steam purifiers are installed between the saturated outlet of the boiler and the superheater inlet, and have a capacity of 150,000 lb. per hr.

Because of the good quality of the feed water and the fact that moisture in the steam is principally due to mechanical entrainment rather than priming caused by chemical salts, it was found advisable to return the water separated from the steam back to the boiler. This method of draining has been successful because of the low-pressure drops through the purifier.

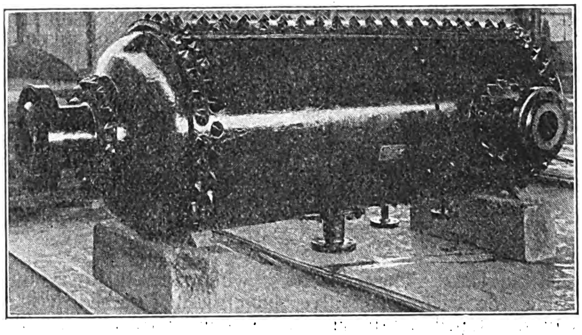

FIG. 76—STEAM PURIFIER FOR 650 LB. PRESSURE, COCHRANE CORP.

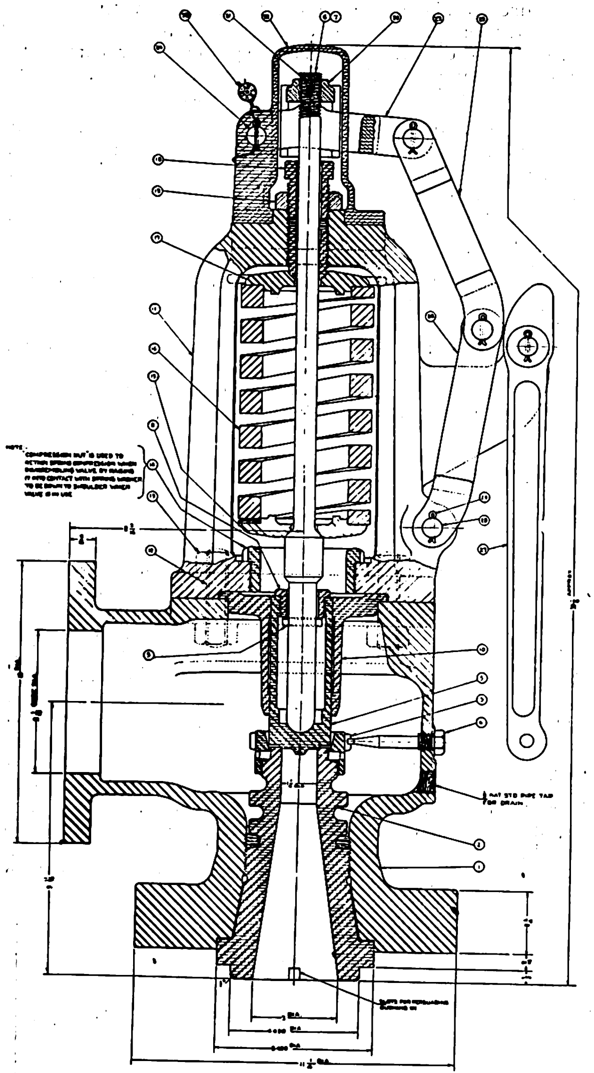
The Waldorf Paper Products Co. of St. Paul, Minn., has installed two steam purifiers on its single pass Edge Moor boilers. These purifiers each have a capacity of 250,000 lb. per hr. at 650 lb. Cochrane forged steel dischargers were furnished for draining the steam purifiers. Fig. 76 illustrates the construction of Cochrane steam purifiers for this pressure.

VALVES

STATEMENT BY THE CONSOLIDATED ASHCROFT HANCOCK CO., INC., BRIDGEPORT, CONN.

Safety Valves

In offering an improved line of high-pressure safety valves, it was realized that positive control of blow-down is the



NOTE: COMPRESSION NUT IS USED TO RETAIN SPRING COMPRESSION WHEN DISASSEMBLING VALVE BY RAISING IT INTO CONTACT WITH SPRING WASHER TO BE DOWN TO SHOULDER WHEN VALVE IS IN USE

FIG. 77—SAFETY VALVE FOR 700 LB. TO 1500 LB. PRESSURES, CONSOLIDATED ASHCROFT-HANCOCK CO., INC.

prime requisite. The capacities, which are the maximum possible for each size valve, have been obtained with a newly developed single ring blow-down adjustment. The cut of this new model in its highest pressure range is shown in the Type 1557 valve, Fig. 77, for pressures from 700 to 1500 lb. This shows the adjusting ring to be similar in shape and general design to previous Consolidated rings, except for the addition of a steam vent or passage from the huddling chamber downward through an open annular ring and holes drilled in the side. This vent is too small to affect materially the pop action and lift of the valve, but at the reduced pressure of valve closing it removes enough support from the disk to permit its closing more quickly and sharply for a shorter blow-down.

The anti-distortion seat bushing is an improved development (patented May, 1928) of the original reinforced bushing (patented June, 1915), which the company has furnished in marine valves and in all high-pressure power valves. This bushing has a fluted exterior shape, presenting alternate yielding and unyielding sections, adapted to prevent transmission of distortion from the valve body to the valve seat. The improvement consists in lowering the point of attachment of this bushing to the valve case to a point where the case distortion to be absorbed in the bushing is less, i.e., to the bottom surface of the valve inlet flange.

In addition to these anti-distortion features of the seat bushing, all steam pressure beneath the valve is contained within the forged or high nickel alloy bushing and does not reach the body casting of the valve, which is exposed only to exhaust pressure at periods when the valve is blowing.

Other new features are the guiding of the disk from above, which removes all obstructions to the flow of steam through the throat of the valve; the use of a compression nut, 14, at the bottom of the spring, which permits retaining the set spring compression when disassembling the valve; the cover studs, 12, are now through studs with nuts on both ends and no threading in the flanges, eliminating the possibility of studs breaking off in the flange; the method of guiding the disk practically eliminates all escape of steam from the case while the valve is blowing. Regular Consolidated high-pressure construction is followed throughout, such as in the toggle lifting gear, the full ball-bearing spring mountings, the long length disk guiding and the substantial lock-up.

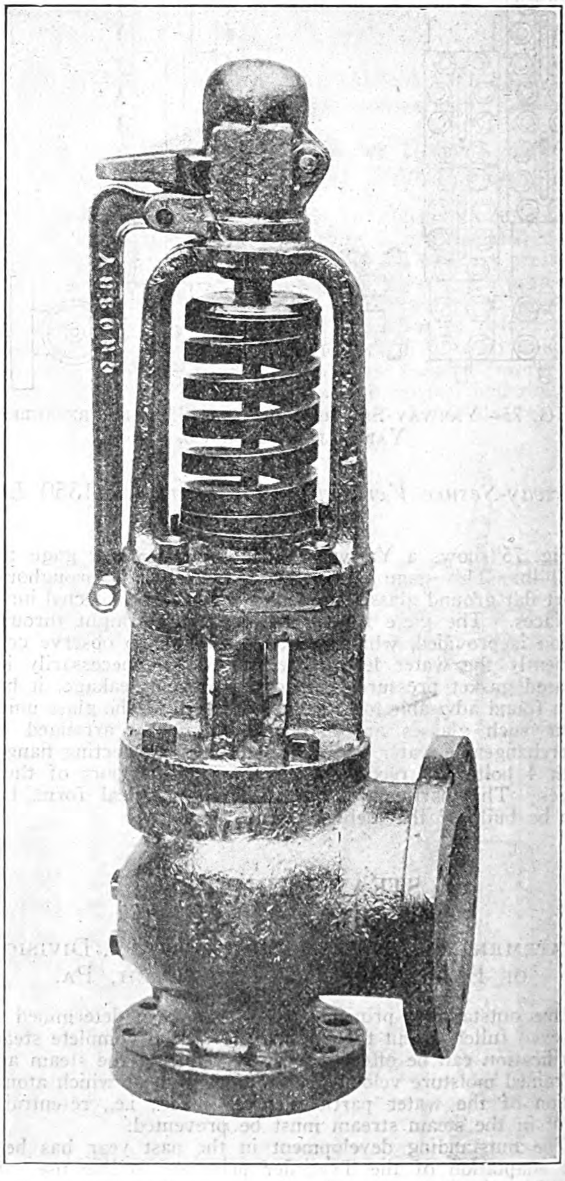


FIG. 78—SAFETY VALVE SHOWING SPOOL INSERTED TO PREVENT HEATING OF SPRING, CROSBY STEAM GAGE & VALVE CO.

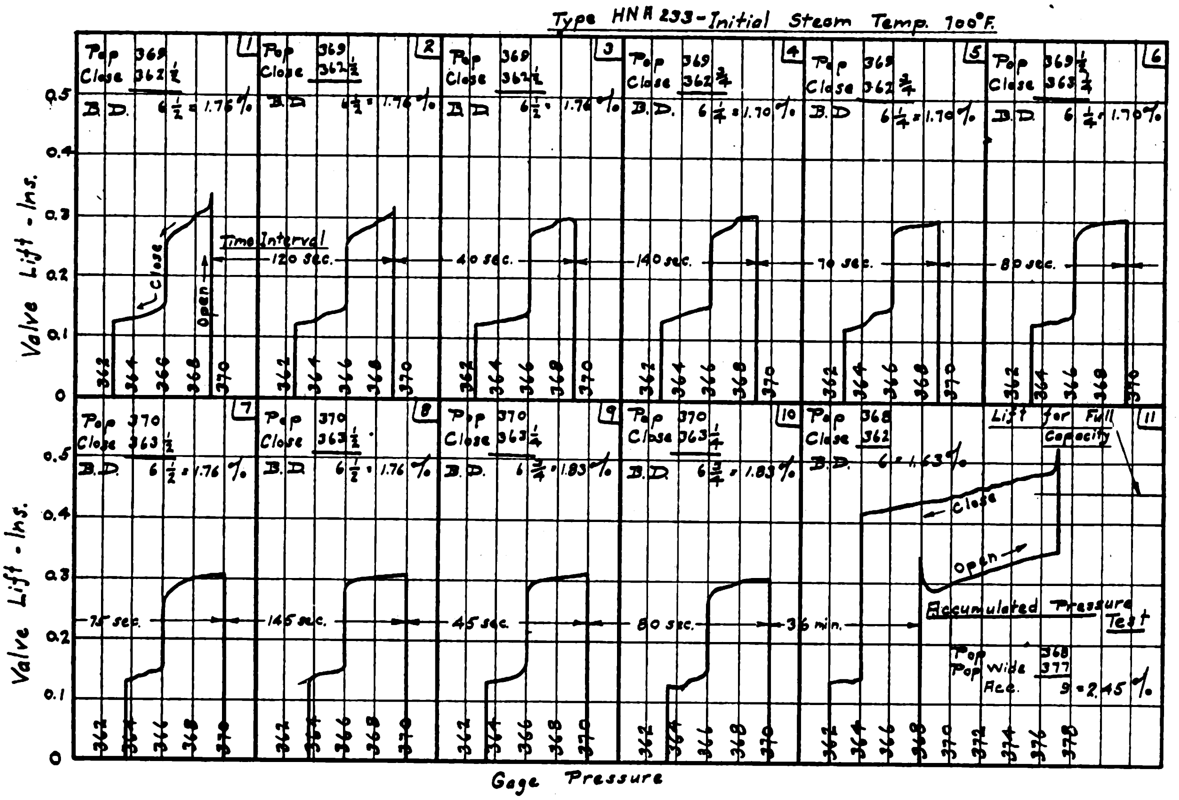

FIG. 79—TYPE HNA SAFETY VALVE CLOSING DIAGRAMS, CROSBY STEAM GAGE & VALVE CO.

STATEMENT BY THE CROSBY STEAM GAGE & VALVE CO., 10 ROLAND ST., BOSTON, MASS.

Safety Valves

The 1926 and 1927 reports contained statements covering the development of the Crosby nozzle type safety valve and the application of the general design to safety valves for all services up to 1500 lb. pressure at 750 deg. fahr. Practical experience with this style of valve now covers a period of over five years, during which no essential changes of design have been found necessary, while at the same time many important refinements have been included, such as closer regulation of blow-down to 2 per cent instead of 4 per cent, as permitted by the Boiler Code. Actual experience has demonstrated that the nozzle type design effects very real economies. Its high discharge capacity permits the use of fewer valves per boiler; the stiff conical nozzle with its seat completely removed from the effects of possible body distortion, and the small symmetrical disk (both parts being high alloy steel forgings), together with the 90 deg. knife edge seats, have reduced leakage troubles to a point formerly thought impossible, thus reducing maintenance costs to a minimum.

During the past year particular attention has been paid to safety valves for service on superheater outlets. In order to protect the superheaters these valves are usually set to blow before the valves on the boiler drum, and so do most of the work under average service conditions. All safety valves must be permitted a proper blow-down to insure proper operation, and this blow-down is always allowed for in determining the set pressure for the superheater safety valves. Having determined the set pressure, however, it is important that the valve pop consistently at this pressure, and close at the pressure corresponding to normal blow-down below it. Any decrease of popping or closing pressures may interfere with station operation.

During the intervals between pops, a safety valve forms a dead end and, even when mounted on a superheater outlet, the valve body and other parts cool down considerably below the temperature which they attain when the valve pops. The closer the spring to the valve body, the more is it subject to these changes of temperature. It is a fact, confirmed by many experimenters, that the modulus of elasticity of any steel, and hence the load which any spring will carry at a given deflection, fall off fairly rapidly with quite moderate increases of temperature, returning to their original values when the original temperature is re-established. This condition cannot be prevented; it is entirely distinct from any question of spring "set," which results from exceeding the elastic limit of the material. As a result, a safety valve will pop and close at lower pressures if the spring is warm than if the spring is cool; to avoid such changes of popping and closing pressures, the temperature of the spring must be kept as nearly uniform as possible.

In the regular Crosby nozzle type HN valves, the spring is entirely above the valve body. This arrangement, while showing a marked improvement over other arrangements, has not been found adequate to prevent all heating of the spring when the valve is relieving high-temperature superheated steam.

To remove entirely the spring from the valve body and to keep it as cool as possible, an extra "spool" has been inserted between the body and the spring yoke or valve bonnet, as shown in Fig. 78. This spool is designed to provide as little metal for conduction of heat from the body to the yoke as is consistent with adequate strength, together with as great a surface as possible for air cooling. This spool can be applied to any regular HN type valve, a longer spindle and a small collar being the only other parts required.

Fig. 79 shows actual tests on a type HNA valve fitted with this cooling spool, mounted on the superheater outlet. The valve was set to pop at 369 lb., the steam temperature being approximately 700 deg. fahr. The diagrams have been carefully traced from the originals, made by means of a lift indicating device, and show the relation of valve lift to pressure. Ten consecutive pops were made, as closely following each other as the pressure could be manipulated. For the ten blows neither the popping nor closing pressures varied more than 1 lb., the blow-down throughout being slightly under 2 per cent. After a wait of about half an hour, a test was run in which the pressure was built up above the popping pressure, to establish the maximum lift and discharge capacity according to A. S. M. E. rating (the A. S. M. E. Boiler Code states that the rated discharge capacity of a safety valve shall be determined at a pressure 3 per cent in excess of that at which the valve is set to blow). Here also the pop and blow-down pressures did not vary more than 1 lb. from those of test No. 1.

These tests not only demonstrate the accurate operation of the valve under this severe temperature, but show the action clearly. As will be noted, the pop is clean and sharp to a lift of about 5/16 in. Closing takes place in two steps, the final drop being from a lift of about ⅛ in. If the pressure increases above the popping pressure, the valve jumps to a lift greater than that necessary to develop "full-bore" capacity of the nozzle, well within the 3 per cent accumulation limit set by the A. S. M. E. Code. With reduction of pressure, closing takes place in two steps, the final drop being as before from a lift of about ⅛ in. These tests show clearly that the valve disk closes on a steam cushion, and thereby eliminates danger of producing a hammer blow.

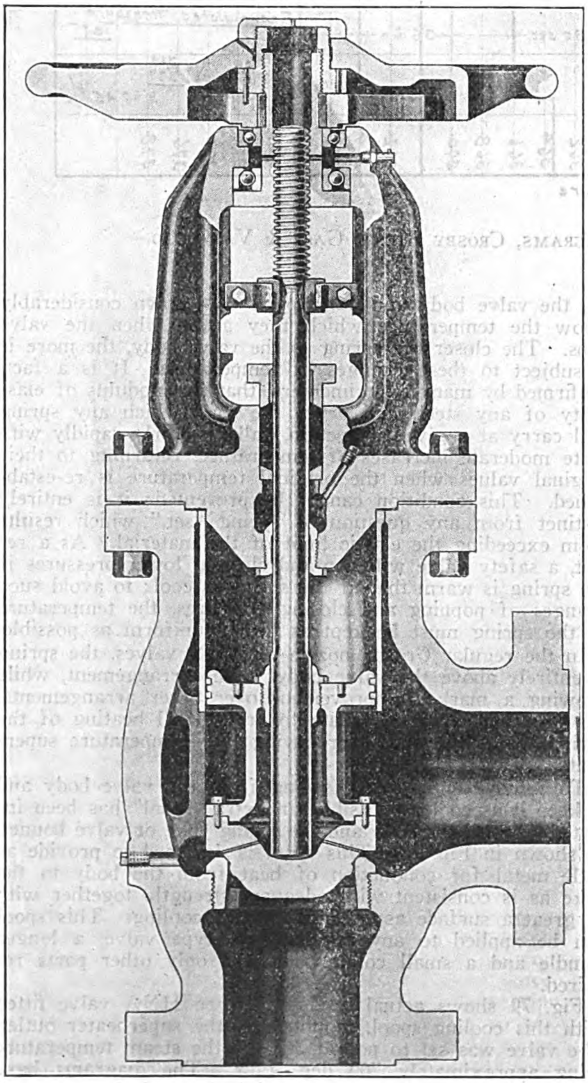

FIG. 80—NON-RETURN VALVE FOR 1350 IB. PRESSURE, THE EDWARD VALVE & MANUFACTURING CO.

STATEMENT BY THE EDWARD VALVE & MFG. CO., 1200 W. 145TH ST., EAST CHICAGO, IND.

Outstanding developments of recent months in connection with design of Edward valves for high-pressure, high-temperature service include:

1. New designs in non-return, blow-off and forged steel stop valves for 1350 lb., 750 deg. fahr. total temperature, conforming to A. S. A. standards. Fig. 80 shows a non-return valve with integrally machined dashpot liner of monel metal, cast steel piston with forged stainless steel disk and seat, stainless steel piston rings, yoke bushings with two combination radial and end thrust ball bearings, and an accessible type of stem key retainer sliding between ribs cast in the bonnet legs.

2. Impactor type handwheel (indicated in cut of non-return valve) for closing against high boiler test pressures. Two heavy hammer weights are cast in the handwheel contacting with a cast steel tee handle keyed to the revolving yoke bushing. This device permits equally distributed application of sufficient force to both ends of the tee handle to enable one man to seat the valve tightly against any required pressure.

3. "Separated" type drumhead stop-check valve, Fig. 81, in which an angle stop valve and a horizontal check valve are incorporated in a single body, the check valve being easily accessible for regrinding through a removable cover. As the stem is in a horizontal position, this type lends itself readily to sprocket wheel and chain operation. With the addition of a single stop valve, this combination meets the minimum boiler code requirements for feed pipe valves. This valve has been manufactured in pressures up to and including 1350 lb.

4. More frequent use of spur gear trains for manual operation of stop valves in connection with higher pressures.

5. Noticeable increase in the use of bleeder line non-return valves.

6. Redesign of blow-off valves for 250 lb. pressure, A. S. A. standards, embodying such features as reversible seats and disks and a compression spring to compensate for thermal expansion and contraction.

STATEMENT BY THE YARNALL-WARING CO., CHESTNUT HILL, PHILADELPHIA, PA.

Yarway Seatless Blow-Off Valve for 1350 Lb.

Fig. 82 shows a Yarway seatless blow-off valve which has recently been built for 1350 lb. boiler pressure. The body and yoke of these valves are steel forgings; the plunger, upper and lower follower rings are of Everbrite; the stem is of steel, and the packing of regular Vulcabeston asbestos fiber material, compressed into a solid yet resilient mass. The lower packing is further protected by armored nickel alloy rings. The valves are fitted with ball thrust bearings and are provided with planetary gear operation when the service demands it.

TURBINES

Abstract

The 1927 report presented the detail operating record for turbines of 20,000-kw. capacity and larger for the year 1925. The present report presents a summary of the 1926 record of 153 turbines, 1927 record of 186 turbines and the detail 1928 record of 207 turbines. The 1928 record shows an increase in the per cent of total time units were available for service and when compared with the 1925 record the unit outage shows a reduction of approximately 25 per cent.

An investigation of the turbine operating methods disclosed that there is no consistency in the time in which cold machines of equal capacity are brought up to speed and loaded. Neither was there found any definite relation between major turbine troubles and the machine operating methods.

Troubles incident to turbine blading form the greatest single cause of turbine outage. This presents a problem that requires most careful attention to details in design, manufacture and operation. In this connection troubles due to deposits in turbine blading were reviewed. Although no method of cleaning blading which would be universally applicable was evolved, information presented should be helpful in suggesting a method of approach when these troubles are encountered.

The majority of operating companies inspect turbines annually. However, a tendency to increase the period between inspections is apparent.

Tests on turbo-generator units ranging in capacity from 6000 to 60,000 kw. are included. In previous years the tests reported were made with the unit operating straight condensing. In this report tests are presented for some units operating on the regenerative cycle with detail data included on the performance of the extraction heaters. The effect of varying exhaust vacua and evaporator operation, on economy when the unit is operated with bleeding; also data for the same unit operated straight condensing and on the regenerative cycle, are included.

The report contains statements by operating companies on new installations, special tests and unusual operating experiences. Also manufacturers' statements on turbine blading, large steam turbines and turbines used for auxiliary drive.

A bibliography concludes the report.

COMMITTEE STATEMENT

Review of Present Trend in Turbine Design and Operation

The survey made by the Committee and upon which this report is based, appears to indicate that since the last report, in 1927, the trend in the industry has been toward the use of higher steam pressures, increased capacity per unit installed, a reduction in the ratio of average yearly installed capacity to system demand, a reduction in the average outage of units reported, automatic control of frequency, and more care in station operation particularly with regard to the starting and stopping of large units.

There were many developments in design and manufacture of turbines such as the more extensive use of steel castings, greater use of non-corrosive blade material, more efficient and rugged blade or bucket fastening as exemplified by the general use of the outside dovetail by the General Electric Company and the serrated type of fastening by the Westinghouse Electric & Manufacturing Company, improvement in blade finish eliminating sharp edges and surface marks thereby reducing the tendency for cracks to develop, and improvement in provision for freedom of expansion particularly at the high-pressure end.

The present capacity limit for turbines to be installed is 75,000 kw. for single cylinder, 160,000 kw. for tandem compound and 208,000 kw. for cross compound units. Machines of a capacity up to 165,000 kw. are being built for operation at 600 lb. per sq. in. and up to 55,000 kw. capacity for operation at 1200 lb. per sq. in. steam pressure.

The mercury turbine now seems to have been developed to a favorable degree. It is estimated that a combined steam and mercury plant can be built to produce a kw-hr. from 10,500 B.t.u. and at a cost worthy of its consideration.

The Westinghouse Electric & Manufacturing Company adopted the so-called hydraulic type of governor for large units. Governors of this type had been in use for many years on small turbines. Favorable reports were received from operating companies on the performance of this new type of speed control equipment on large machines.

There is at present no apparent trouble on units

Publication No. 289-98. Serial Report, Prime Movers Committee.

reported that is of a general nature. Some isolated cases have proved very stubborn of correction.

There seems to be little, if any, improvement in the average availability of turbines during the first year of service. This is probably due in a large measure to the impossibility of operating large turbines under power station conditions in the manufacturers' shops. A considerable amount of development and correction of defects of design and manufacture must be done in the field.

It is believed that the manufacturers are seeking diligently to hold such field development to a minimum. Perhaps a standardization by our industry on sizes, types and operating conditions would do more to improve steam turbine operation than may be accomplished in any other manner.

RECENT LARGE TURBINE ORDERS AND INSTALLATIONS

The average capacity of turbo-generator units installed by operating companies increased very rapidly in recent years. During 1928, turbines were placed in operation that for the first time exceeded a unit capacity of 100,000 kw. The largest unit now in service is the 165,000-kw. triple cross compound unit at the Philo Station. The 208,000-kw. triple cross compound unit for the State Line Generating Co. will soon be in operation.

Units now on order establish new capacity records for machines of their particular type and include two units rated above 100,000 kw. The maximum capacity of the single-cylinder type of turbine increased from the 65,000-kw. unit at the Edgar Station to the 75,000-kw., 1800-r.p.m. unit for the Cahokia Station. The multi-cylinder, tandem-type of turbine increased in capacity from the 94,000-kw. unit at Long Beach Station No. 3 to a 160,000-kw. unit on order for the East River Station.

There is a greater use of steam at higher pressures as evidenced by the machines on order or recently installed. The 10,000-kw., 1200-lb. per sq. in. turbines at the Edgar and Northeast Stations represent the highest capacity of this type of machine now in operation. Deepwater and Holland Stations have on order 1200-lb. per sq. in. turbines that will operate as high pressure elements of cross compound machines rated respectively at 53,000 and 55,000-kw. capacity.

Table I shows the large or special turbines that were recently placed in operation. Table II presents similar data for turbines on order or under construction.

TURBINE OPERATING DATA

1926 and 1927

The performance of 153 machines for the year 1926 and 186 machines for the year 1927 was analyzed. Operating data for these years, presented in Table VIII, are used in determining the general trend of unit performance over a period of years.

1928

The operating data of 207 units, ranging in capacity from 20,000 to 110,000 kw. were compiled for the year 1928. The operating factors and the causes of outage are presented in detail to show the trend in the performance of these machines.

The operating records for each of the 207 machines, for the year 1928, are graphically presented in Table III. In this table the units are classified according to their first service year and the per cent turbine capacity used. The annual period of 8784 hours is divided into the time the machine was operated, the time it was in reserve and the time during which it was unavailable to carry load because of an outage of the turbine, generator, condenser or because of other conditions not attributable to the unit.

The capacity of the unit and the identification number, the same as that used in the 1927 report, are shown at the left margin of Table III. The letters A, B, C and D, at the right margin of this table, refer to the manufacturer of the turbine. The letters S., T. C., and C. C. refer respectively to single cylinder, to tandem compound and to cross compound types of turbines.

A summary of the operating record is shown in Table IV. In Table V the operating and outage factors are tabulated with respect to the first service year of the machines included in the 1928 operating record.

The 207 turbo-generators are classified in Table V according to the character of service to show the system demand for the machines. The relation between the demand and the availability of these units is presented in greater detail in Table VI, where the machines are classified according to the service demand factors. A service hour classification of machines is presented in Table VII to show the relation between operating and outage time with the units grouped according to their first service year.

The 1928 service record of each machine is graphically presented in Fig. 1. In this figure are shown the total outage hours, the service hours and the reserve hours in per cent of total period hours for every unit reported and the general distribution of outage for all units. The machines with high service hour factors are not the machines that show a high total outage. Turbo-generators that are normally in continuous service and operate more than 80 per cent of the time show a total outage of only 5.77 per cent. The total outage increases with a decrease in operating time until service hour factors are

reached, when the machines are no longer needed to meet daily peak load or operating reserve capacity requirements. The high outage between service hour factors of 40 and 80 per cent seems to indicate that starting and stopping turbines influences the availability of machines.

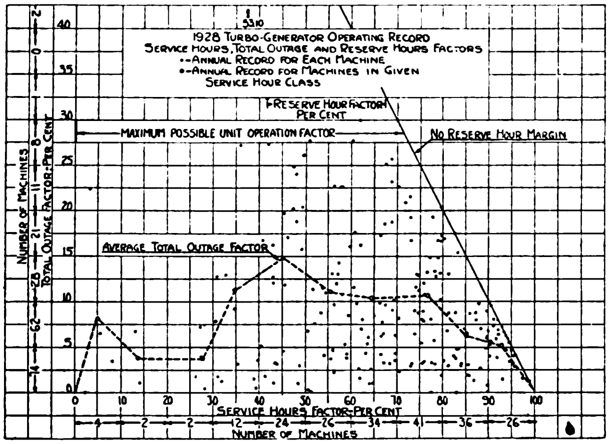

FIG. 1—OPERATING AND OUTAGE FACTORS FOR ALL TURBINES IN 1928 OPERATING RECORD.

It is apparent from Fig. 1 that machines with a high outage factor, with less than approximately 10 per cent reserve factor, are machines of the base load type that would have operated practically continuously had no forced idleness been encountered.

The relation between the time the machines operated and the per cent of the operating time the machines were out of service for repairs is shown in Fig. 2. Although the total outage decreases with service hour factors below 40 per cent, the ratio between total outage and operating time increases.

Comparison with Year 1925

The data summarized in Table V are graphically presented in Fig. 3, 4, 5 and 6, where data from the 1925 operating record are also shown. It is significant that a fairly consistent relation existed between the service year and the number of turbine reports received for respective service years. This also held true when the units were segregated with respect to class of service as shown in Table V. This consistency in the class of service and the number and age of turbines reported adds to the reliability of conclusions that might be drawn when the performances of these units, during 1925 and 1928, are compared.

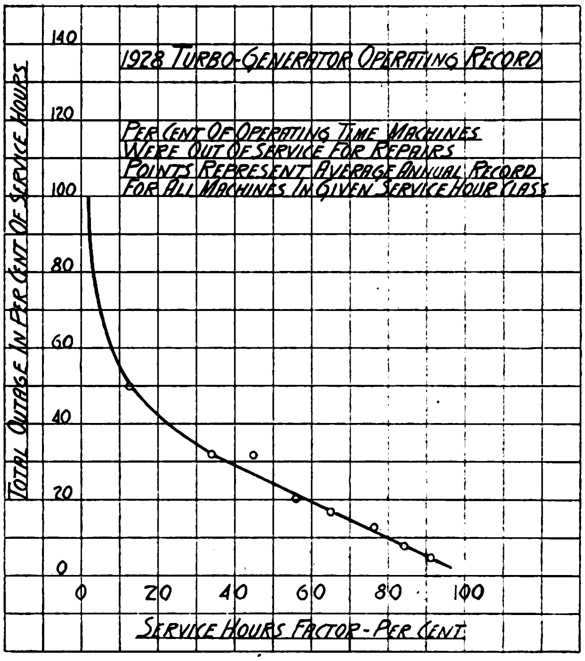

FIG. 2—PER CENT OF OPERATING TIME MACHINES WERE UNAVAILABLE, 1928 OPERATING RECORD.

An improvement in the availability of units is apparent when operating records for years 1928 and 1925 are compared. An inspection of Fig. 4 discloses that the outages caused by the turbine for machines installed the same year show an appreciable reduction. The generator and the condenser show a smaller per cent reduction in caused idleness. However, the per cent improvement in both of these cases exceeds that effected by the turbine. Fig. 3 indicates that the service hours factor remained practically unchanged, the reduction in outage manifesting itself in the form of increased reserve capacity. The reserve hours factor curve indicates, as would be expected, a decreasing trend as the more recently installed machines are reviewed.

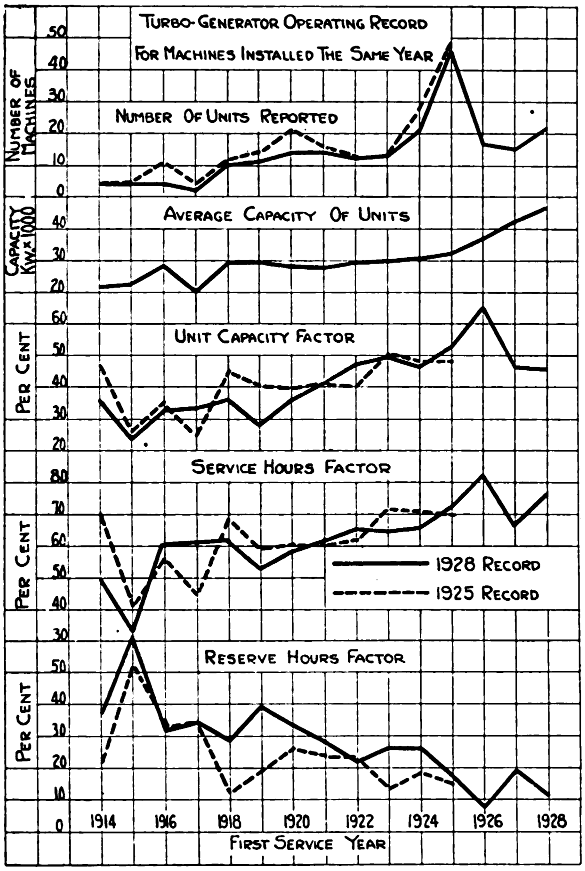

FIG. 3—OPERATING FACTORS FOR TURBO-GENERATORS INSTALLED THE SAME YEAR.

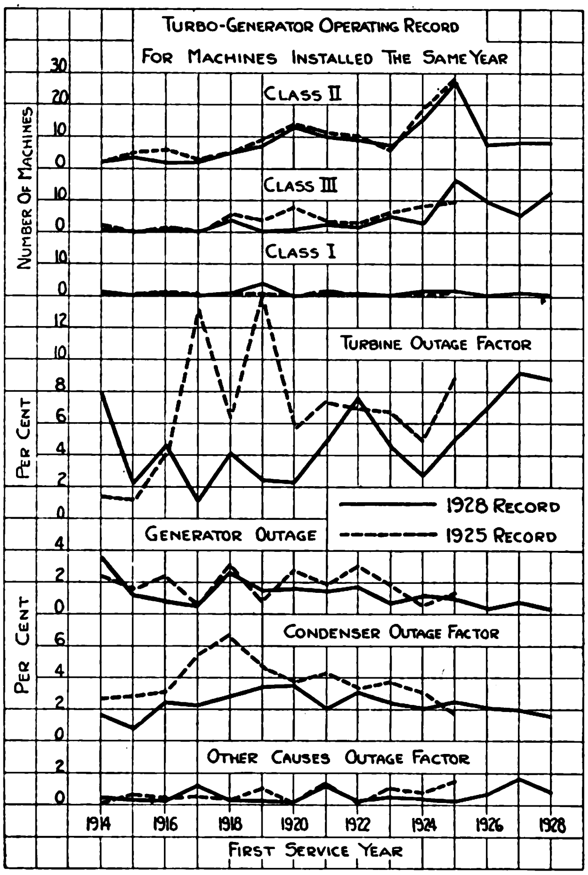

FIG. 4—OUTAGE FACTORS FOR TURBO-GENERATORS INSTALLED THE SAME YEAR.

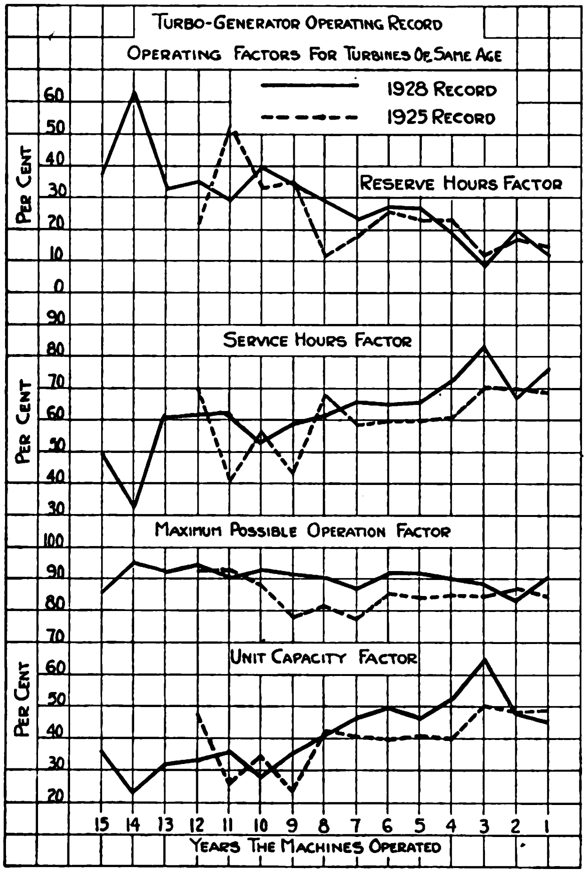

FIG. 5—OPERATING FACTORS FOR TURBO-GENERATORS OF SAME AGE.

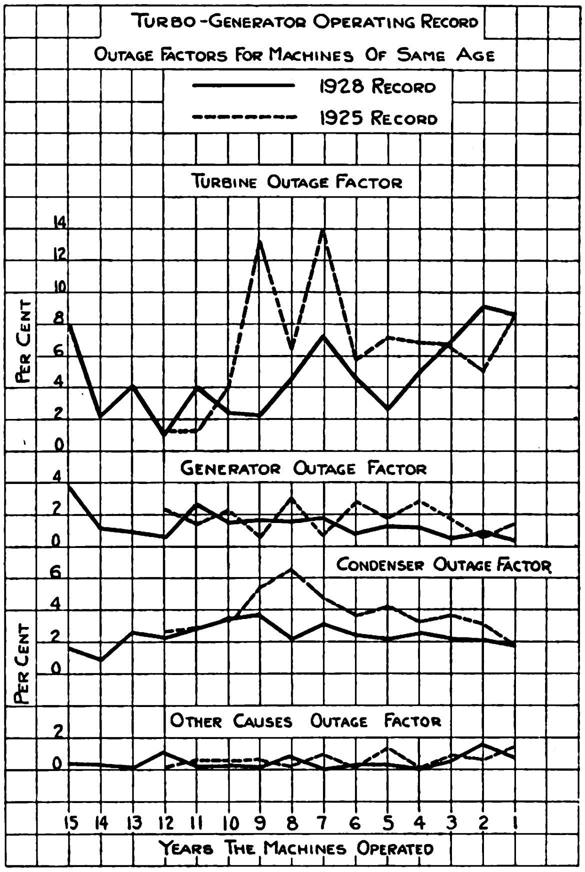

FIG. 6—OUTAGE FACTORS FOR TURBO-GENERATORS OF SAME AGE.

The service year 1925 showed an unusually rapid increase in the generating capacity installed by the companies from which reports were received. The increase in capacity installed during the service year 1928 was only 65 per cent of that reported for 1925.

When the operating factors shown in Fig. 5 are compared on a basis of the number of years the machines operated, it is seen that the reserve hours factor remained the same, but the service hours factor and the capacity factor are higher for 1928 than for 1925.

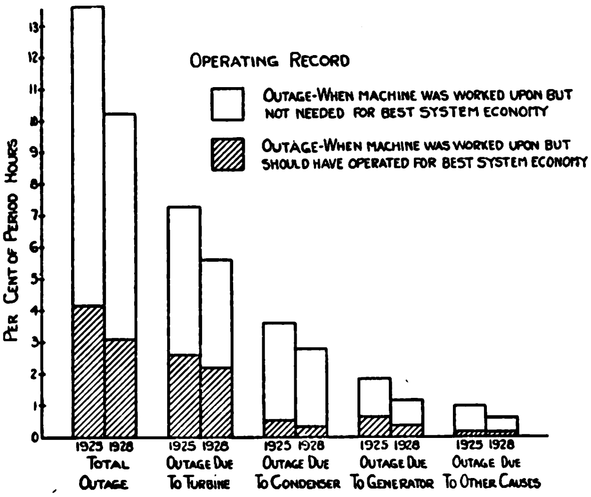

FIG. 7—TOTAL AND DEMAND HOUR OUTAGE OF TURBO-GENERATOR UNITS.

Fig. 7 graphically distributes the total and the segregated outage between the demand and no demand period in per cent of total period hours for the years 1925 and 1928. The 1928 outage, both total and over the demand period, is approximately 25 per cent less than for 1925.

The outage during demand periods is of primary interest. Reduction in idleness during the demand hours is of greater importance than reduction in total outage in which the demand hour idleness has not

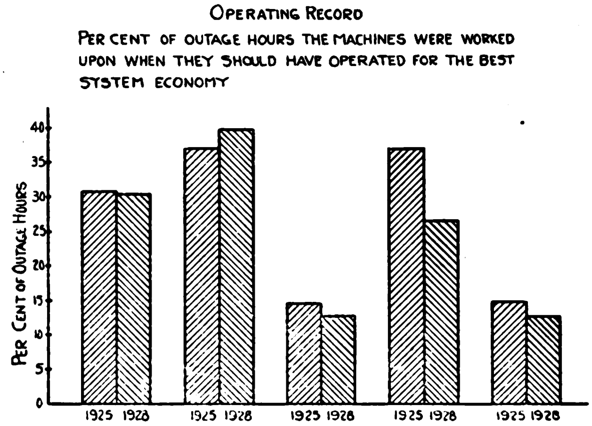

FIG. 8—PER CENT OF OUTAGE DURING THE DEMAND PERIOD.

been reduced. It is appreciated, however, that maintenance during no-demand hours may forestall a future demand-hour outage.

Fig. 8 shows the per cent of outage due to turbine, generator, condenser or other miscellaneous causes that took place at a time when the machines were in demand. All causes of idleness except the turbine show a decrease in demand outage, expressed as a per cent of total outage.

Comparison with Preceding Years

The weighted average annual operating and outage factors for turbines of 20,000-kw. capacity and above without regard to date of installation for the years 1921 to 1928 inclusive are shown in Table VIII. Significant improvements were made in the outage factors for the most recent years.

Increased capacity of the systems very appreciably reduced the annual service hours factor, the unit capacity factor and service demand factor for the year 1925 and increased the capacity of machines held in reserve. For the years 1926, 1927 and 1928 the capacity of units installed apparently increased at a rate more nearly conforming to the load increases of the systems of the reporting companies. The reserve hours factor, however, showed little change as the reduction in the outage factors of the units approximately corresponded to the increase in the service hour factor.

Outage Due to Turbine

An inspection of the turbine outage factor chart, Fig. 4, reveals that the 1928 record appears better than the 1925 record, but it must not be inferred that this was due to improvement in recently installed machines. The 1925 record for the first year of operation is the same as the 1928 record for the first year of operation. The average outage becomes less as the machines become older. From this it is evident that there has been no reduction in the field work on new machines during the last three years. The turbine outage factor during the first two years of operation exceeds 8 per cent, whereas in the later years it is reduced to about 4 per cent.

High turbine outage for machines in their first operating year in 1922 is due to an abnormal turbine outage for one machine in that group. If this machine with a turbine outage factor of 43.20 per cent were excluded from this group the average for 1922 would decrease from 7.62 per cent to 4.0 per cent, which is approximately equal to the average for the preceding and succeeding years. For machines with their first operating year in 1927 and 1928 the outage is not sufficiently localized in one unit to produce an appreciable reduction in outage if it were excluded from the averages reported.

When outages caused by turbine troubles are reviewed, it is found that barring the period of annual inspection, the major causes are buckets or blades. The number of machines affected by bucket or blade trouble increased from 19 during the year 1925 to 41 during 1928, and the outage during machine demand hours increased by more than 300 per cent. This brings to our attention a condition which is most important and one which demands the most strenuous efforts for correction. Present developments indicate a possible reduction in outage due to these causes but it may be several years before the condition becomes more satisfactory.

Outage Due to Condenser

In connection with the condenser 80 per cent of the outage is due to cleaning, with 13 per cent of the cleaning outage hours charged against the unit at a time when the machine should have operated for best station economy.

Operating Records for High Capacity Turbines

The average capacity of units installed by operating companies is showing a consistent increase. Referring again to Fig. 3, it is seen that on a basis of the years when the turbines were first operated the capacity changed very slowly. The average capacity increased from approximately 29,000 kw. in 1918 to 31,000 kw. in 1924. From 1924 to 1928 the average capacity of the turbines reported increased from 31,000 kw. to 46,000 kw. As the general trend is upward, the operating record for units of a capacity of 50,000 kw. and above may be of interest and is presented in Table IX. These data indicate that the turbine caused idleness is greater for these machines than for machines below 50,000-kw. capacity.

TABLE IX

OPERATING RECORDS FOR HIGH-PRESSURE AND HIGH-CAPACITY MACHINES FOR YEAR 1928

	Pressure 550 lb. ga. or above	Capacity 50,000 kw. or above

Turbine outage factor, %	5.60	8.05
Generator outage factor, %	.54	.78
Condenser outage factor, %	5.02	3.47
Other causes outage factor, %	.57	1.16
Reserve hours factor, %	5.87	13.80

Operating Records for High Pressure Turbines

Operating and outage factors for 12 turbo-generator units operating with 550 to 600 lb. per sq. in. gage steam pressure are shown in Table IX. These units, although operating 25 per cent more hours than the average of all other machines, show turbine outage factors that favorably approach the average obtained for all units for 1928. When compared with 1925 record of machines of the same class the outage factors show a decline from 14.75 per cent to the present 5.6 per cent. The improvement can be accounted for by the fact that the 1925 record represented turbines in their first year of operation.

TURBINE OPERATING METHODS

Operation of large turbines was reviewed to determine if there was any relation between turbine operating methods and turbine troubles, other than those due to blade failure. Information is reported on the starting and stopping cycles, instruments used when turbines are placed in service and rates of turbine loading for 135 turbines of 20,000-kw. capacity and above.

Turbine Starting Cycles

The time required to bring cold turbines of the same capacity up to synchronous speed varies considerably in the different stations. In most cases, the starting cycle is scheduled by time which has been determined by machine performance during the rolling period or which has been specified by the turbine manufacturer. In the case of one 1200-lb. per sq. in. turbine reported, the rolling time is governed by the expansion of the turbine casing.

Two stations reported the use of slow turning devices for turbines. In both cases, the rolling period of the starting cycle has been eliminated and the time required to bring the units up to speed is reduced.

Table X and XI give the time required for the various periods of the starting cycles reported.

One point of difference in the starting cycles for impulse turbines is the operation of the seals. In one-third of the stations reporting the operation of impulse machines, the sealing steam for the high pressure packing is admitted previous to rolling. This is no doubt done to obtain a high starting vacuum. In the remaining two-thirds of the stations the high pressure seal steam is admitted immediately after the turbine begins to roll.

In the case of reaction turbines, the seals are applied after the turbine is rolling.

There is a difference of opinion regarding the change of the starting cycle time when the machine is considered as a hot or warm machine. In the majority of cases the starting time of a hot machine is less than that of a cold machine. Some operators do not differentiate between a hot or a cold machine using the same starting cycle for both conditions. In several cases reported, more time is taken to start a hot machine than a cold one, since the hot machine is considered to require more attention while starting due to shaft deflection.

Shaft truth indicators are used in six of the stations reporting. The length of the period of slow roll is determined by the readings of these indicators.

Shutting Down Cycles

Statements in regard to shutting down cycles indicate that in some plants the vacuum is broken immediately after the throttle is tripped or closed, while in others the vacuum is retained for some definite time or as long as it is self-sustained. In one station operating 45,000-kw. tandem compound reheating units, the vacuum is reduced to 20 in. of mercury before the turbine throttle is tripped.

The majority of stations rely upon the throttle valve to keep the steam out of the turbine casing while the machine is out of service. Several stations report that the valve at the header end of the turbine lead is also closed as a precaution against leakage, using an open ended drain between the header and throttle valves to maintain atmospheric pressure in the turbine lead.

Turbine Loading

The minimum loads carried by the various machines and the rates of loading are also presented in Table X and XI. These data indicate that for machines of 30,000-kw. capacity the general practice is to allow a minimum load of 5000 kw. As the capacity of machines increases, the minimum load limit increases, being 10,000 to 15,000 kw. for 35,000 to 60,000-kw. turbines.

The rate of loading turbines is reported as 1000 kw. per minute in most of the plants, although as indicated in Table X and XI the loading rate adopted in some plants varies from this average rate.

Instruments Used

The instruments used for turbine operation vary considerably. Six plants report the use of shaft truth indicators during the rolling periods. Turbine speed is recorded in two plants. The other stations use the hand indicating tachometer, the vibrating reed type of speed indicator, and in a few cases the electric indicating tachometer which comes into operation after the generator field is applied.

The use of recording and indicating pressure and temperature instruments is not standardized. Some stations use recording, whereas others use indicating instruments. This applies to oil pressure and temperature, seal water pressure, throttle steam pressure and temperature and to exhaust steam pressure and temperature.

TURBINE TROUBLES

The report on turbine troubles, other than blade failures, reviews troubles encountered in connection with machines of 20,000-kw. capacity and larger during the years 1926, 1927 and 1928. Table XII classifies the turbines, for which information was reported according to the year in which the machines were first operated.

TABLE XII

SUMMARY OF MACHINES REVIEWED IN REPORT—TURBINE TROUBLES.

Year Installed	No. of Turbines
1918 or before	18
1919	6
1920	10
1921	6
1922	6
1923	11
1924	23
1925	21
1926	18
1927	10
1928	6
Total	135

Major difficulties have been so varied that it appears there is no trouble at the present time that is general on machines installed during the past three or four years. The general troubles on machines installed prior to this time have apparently been corrected by changes in design.

Turbine Casings

A number of turbines installed prior to 1920 were constructed with cast iron high pressure casings. Operating pressures on these units were of the order of 235 lb. per sq. in. gage with temperatures not over 600 deg. fahr. The cast iron casings of six of the machines have been changed to steel due to cracking, while in two other cases the reinforcing ribs on the high pressure cast iron casings have cracked but are still in service. Only one case of cracking of an exhaust casing was reported.

Two cases of cracking of steel casings have been reported. One of these turbines was installed in 1924. After four years of operation with a steam pressure of 566 lb. per sq. in. gage and a temperature of 720 deg. fahr., a crack was found in the lower half of the high pressure casing. In the second instance, the throttle and control valves were installed below the turbine, the steam entering the turbine through a long sweep ell which had a partition in it for separating the steam to the two control valves. Due to expansion strains caused by the divided steam flow, a crack developed in the flanged neck forming an integral part of the lower half of the high pressure casing. This machine was started in 1926, the crack developing after seven months of operation. The operating steam pressure was 375 lb. per sq. in. gage and the temperature 750 deg. fahr. The crack was welded and the piping strains relieved. No further trouble has developed.

Four cases of warping of cast iron high pressure casings and one case of warping of an exhaust casing have been reported. In three of these cases the warped joints were in the vertical plane. These joints were remachined. In the other two cases the warping was in the horizontal plane, but the casing joints were pulled tight with bolts. The machines that have experienced the warped casings were installed in 1924-25.

Turbine Foundations

Statements indicate that the foundations of the turbines reported are satisfactory. Two turbines installed in 1925 were grouted with a mixture of iron borings and salammoniac. This material disintegrated and was replaced with Lumnite cement. In one station it was found that filling the steel box columns of the foundations with concrete resulted in smoother running machines. The concrete has changed the period of vibration of the columns.

Vibration was experienced on three machines installed in one station which started operation the latter part of 1925. The foundations are of steel and it was thought that the design was responsible for the turbine vibrations. Additional stiffening steel was added to one of the foundations, but did not improve operation. Changes were made in the turbines which eliminated the difficulty.

Bearings

Statements indicate that there has been no trouble with the main unit bearings.

Several cases of failures of the single plate type thrust bearing have been reported. These have in most cases been replaced with multiple plate type bearings.

Five stations reported that the generator thrust bearings have given trouble. Analysis of these failures indicates that they occurred on machines installed prior to 1921. This condition has apparently been corrected on machines of the present design.

Shafts

Three cases of sprung shafts on impulse turbines are reported. The shaft of one 25,000-kw. machine installed in 1926 had sprung 0.015 in. and was straightened. The other two cases occurred on two machines of 50,000-kw. capacity installed during 1924 and 1925. New shafts were installed in these two units.

The steel shrink links on a 40,000-kw. reaction type turbine installed in 1922 stretched causing the high pressure spindle to run out of alignment. New chrome nickel steel links were installed to correct this trouble.

Another station operating a 22,000-kw. reaction turbine, installed in 1921, reported the spindle had cracked through the balancing and equalizer holes on the governor end of the machine, making it necessary to install a new central section of the spindle.

Steam piping strains caused a spindle rub, resulting in blade failures and a bent spindle. This accident occurred in 1927 on an old reaction machine following repairs to the dummy strips.

High and Low Pressure Seals

The low-pressure seals are apparently giving satisfactory results.

In the case of the high-pressure seals, two stations reported that machine vibration was caused by steam leakage between the shaft and the rotating element of the seal causing unequal heating of the shafts. In one of these instances the seal rubbed and had to be renewed. In both cases the new seals installed had grooves cut on the inner circumference of the rotating element so that in case of steam leakage it would be distributed around the grooves, preventing unequal heating of the shaft. The machines on which this trouble occurred were of 30,000 and 35,000-kw. capacity, installed in 1926 and 1928.

In two plants the combined water and steam high-pressure seals were changed to a steam-sealed type. These two machines were installed in 1926 and 1927. In one case water from the seal was pulled into the machine and caused dishing of the first stage wheel resulting in a rub.

Two stations reported that the use of steam and water for sealing on the same bronze packing gland runners resulted in cracking and loosening of the runners. They were replaced with steel runners. In one of the above cases the use of steam for sealing has been discontinued.

Operating Governors

The operating governors have given practically no trouble. One case of a broken governor spindle has been reported.

Couplings

No difficulties have been reported with couplings.

Oil Pumps

Turbine oil pumps were reported as giving satisfactory service.

Throttle and Control Valves

Six stations report steam leakage between the seat rings and the casings of throttle valves. This trouble is apparently confined to the older units, since there were no reports of this nature on the more recently installed turbines.

One case is reported where the wrought iron studs in the bottom bonnets of the control valves on two 50,000-kw. machines installed in 1924 had crystallized. These studs were replaced with special steel studs.

In the case of an 80,000-kw. unit installed in 1926, a cap bolt in one of the main valve cages loosened due to broken binding wires and passed into the turbine, causing damage to the first stage blades and nozzles. The binding wires were replaced with lock washers bent up around two flats of the bolt head and crimped into seats.

TURBINE BLADING TROUBLES

This investigation covers 100 machines, totaling approximately 2,750,000-kw. capacity, which encountered blading failures during the years of 1926, 1927 and 1928. Most of the machines were of 20,000-kw. capacity or larger. Some of the turbines experienced repeated blade troubles over a period of years, but these additional failures have not been used in computing the totals reported. A large number of the machines had been in operation from two to four years. Care was taken in using data submitted from older machines as it was recognized that there has been an advancement in turbine blade design and material in the past five years. Many blade troubles are related to other turbine troubles, and failures which could be traced to or which accompanied other troubles such as thrust or dummy failures, etc., were not considered.

The troubles considered include in addition to blade failures proper, fractures discovered before actual failure, damage to or loss of shrouding sections, fractures of lacing wires or soldered lacing wire connections resulting in damage to blades, some root troubles and a few cases of cracked tenons under the shroud bands. Many of the blade troubles reported were discovered before actual failure had occurred. Often these discoveries were made by close inspection by the manufacturer's engineer during annual overhaul or upon special inspections made by or at their suggestion.

The Committee is not in position to make complete analyses of the causes of the failures. Such analyses can only be made by the manufacturers' turbine engineers and blading specialists with full detailed knowledge of turbine design, detailed blade design, blade loadings, allowable stresses and other details. However, from the information on hand it is possible to roughly group turbine blade failures into the two following classifications:

1. Those for which no apparent cause can be found and which apparently bear no definite relation to failures in other machines.
2. Those for which cause is discovered by inspection after the development of trouble or which apparently bear some relation to similar troubles in other machines.

A large number of failures can be grouped under the first classification. Many blade failures are discovered for the first time on opening the machine for annual inspection. Their presence was not suspected by the operating force, and apparently no indication was given or noticed, and no unusual noise heard at time of failure.

Often a number of failures may be linked together to form evidence which points to some weakness of design or other probable cause of trouble. In this group may be classed the failures of the longer blades in the lower stages of certain sizes of impulse turbines and of the shorter intermediate blades in reaction machines. It must not be assumed that the causes of failure are the same in every case.

Failures Result of Fatigue

From the evidence available, failures of the longer impulse blading cannot be attributed directly to the primary stresses due to centrifugal force, to impact, to pressure differences across the blading, or to blade loadings. Failures are rather the result of fatigue due to vibration. In a few of the cases reported the failures have been hastened by erosion and corrosion but it is believed failure would have ultimately occurred from vibration alone. The stresses caused by vibration cannot be easily analyzed mathematically. Therefore, the problem must be solved by direct research and by actual experience.

Failures in reaction machines have appeared in the intermediate sections and on blades and shapes deemed amply strong through years of service. Such failures probably result from a combination of the primary stresses rather than from vibration which would be more apt to manifest itself in the longer blades. These troubles have resulted in revision of methods of blade calculations to include factors previously deemed unimportant.

All the turbine builders have continued their study of blade design and have conducted extensive research into the problems presented by vibration. The methods used consist in general of testing to destruction many shapes of blading under the influence of various forms of vibration. This research includes the effect of position and shape of lacing wires and their fastenings and also the materials of blading.

Improvement Over Old Materials

The use of Ascoloy, stainless steel or chrome iron alloy is increasing for replacement as well as new blades. The data submitted were not sufficient to definitely determine the comparative resistance with respect to steel and other alloys against erosion, corrosion and similar troubles. The few reports received indicate considerable improvement over the old materials, and this checks with manufacturers' shop experience. It has been pointed out that stronger materials are available, but of the blading materials thus far developed chrome iron alloys apparently best combine the requirements of strength, resistance to erosion and corrosion, reasonable ease of working by ordinary shop methods, possibility of soldering without alteration of structure and resonable cost.

The use of lacing wires upon replacement of the longer blades is continued. In an effort to stiffen blading some applications of binding wires were made to blade shapes which have shown a tendency to fail through vibration. The application of tie wires to blades which are not primarily designed for their use must be regarded as somewhat experimental and while it may clear up the existing situation it does not completely eliminate the causes.

Improved blade roots and fastenings and better fitting of roots have also reduced blade vibration. With these and the use of much heavier and stiffer blades with well-rounded edges and large radius fillets, future troubles from vibration should decrease.

Some blade troubles may arise from the use of higher steam temperatures, particularly in the larger sized machines, which call for more skill and care in handling during the starting and stopping periods. Manufacturers of large turbines are fully aware of the seriousness of blade failures. They are carrying on extensive research in the hope of improving present designs and materials. It is not possible to simulate in a laboratory actual operating conditions. Therefore, at present, it appears that much of their information must be gained from operation in the field.

An attempt was made to ascertain the benefits of corrective measures which have been applied but sufficient data are not available to give definite conclusions. It seems that initially manufacturers applied lacing or tie wires to existing blades in an attempt to stiffen them. In one or two instances these were not entirely successful and later troubles were corrected by complete replacement. The use of silver solder to build up eroded edges has been successful in most instances, except where probably a good bond was not obtained.

Manufacturers' statements on turbine blading supplement the Turbine Blading Trouble section of this report.

MANUFACTURERS' STATEMENTS ON BLADING

The Prime Movers' Committee Does Not Accept Responsibility for any Manufacturer's Statement

STATEMENT BY THE ALLIS-CHALMERS MANUFACTURING COMPANY, MILWAUKEE, WIS.

Steam turbines manufactured by the Allis-Chalmers Co., 20.000 kw. and larger in capacity, are in service in five power plants in the Middle West, with a total of eight units.

The only blading renewals were as follows:

Two rows of moving and stationary blading in a 25,000 kw. unit.

One row of moving and stationary blading in a 25,000 kw. unit.

These two machines are located in the East Peoria Power Plant of the Illinois Electric Power Co., Peoria, Ill. They have both practically completed their fourth year of continuous operation. The replacements were of relatively small blading in the intermediate section of the turbines and were made during the regular inspection periods. There were no shut-downs of any of the eight machines because of blading failure.

The blading material in all of these machines has been of nickel-copper and nickel-chrome alloys that are corrosion resisting and in this company's judgment, more resistant to corrosion than stainless iron. For twenty-five years this company has not used a material for blading that is not of the non-corrosive type of metal.

The nickel-copper alloys used have been of two types, cupro-nickel and Monel metal. For the larger machines a limited amount of cupro-nickel is used for stationary blading in the intermediate and lower pressure stages. All of the moving blading is made of either Monel metal or the nickel-chrome alloy mentioned; this last alloy containing approximately 20 per cent nickel and 7 per cent chrome.

The blading research, as conducted by this company, covered the subject of blading vibration, strength of material at all temperatures, erosion, and fatigue strength of the material in round bar form and also in actual blade shapes and at different temperatures.

The work of this company in connection with the effect of vibration on turbine blading has been generally in the direction of making a structure or assembly of blading having a relatively high natural frequency.

This company tests the relative resistance of blading material to erosion on turbines in the power plant at their factory. Tests are continuous and are conducted over a period of years. They are performed by installing, in the same row of blading in a turbine, blades made of different material.

Research in the fatigue of blading material has been conducted for this company by the University of Illinois Experiment Station. The results of the tests of material submitted by this company for fatigue strength at room and high temperatures have appeared in publications of the university. The most recent publication on turbine blade material used by this company is contained in University of Illinois Bulletin No. 183. The material furnished the university was taken from stock shelves without any additional or special finish on the surface or on the edges. The knowledge made available by such tests is most valuable in determining the limiting load to be applied to an actual turbine blade.

STATEMENT BY THE GENERAL ELECTRIC COMPANY, SCHENECTADY, N. Y.

Present Situation

During 1928 improvement was made in the bucket situation, especially as regards the so-called light last stage buckets initially placed in service in 1924 and of which the first failure was reported during 1927. The use of this type was discontinued immediately when the failures were reported and their gradual elimination from machines in service has been attended with a corresponding improvement in service record.

This company has never lost any buckets due to primary or centrifugal stresses either in the body of the buckets or in the dovetail connections. All failures have been due to the presence of vibration as is evidenced by the fractures displayed. But no one single disease is common to all cases. It is necessary to take account of the particular type of vibration involved and also the strength or special points of weakness of the bucket in question, the stimulus present, the maximum value of which bears a definite relation to the load, the margin from resonance, and the ability to resist the development of stress as well as the strength of the dovetail connection and of the materials involved.

Investigations

Systematic tests are being carried on in reference to all the above factors. These tests involve shop experiments which range all the way from observation of the special behavior of a bucket under actual operating conditions of speed, load and steam conditions to analytic determinations by means of thousands of test samples of the properties of materials to withstand fatigue under actual operating conditions in regard to steam pressure and temperature.

Analysis of Service

The ultimate test of success with which all results must eventually be compared is the test of service in the machine. On this account, complete and careful service records of all buckets in all machines are kept and thorough analyses are made as to the success of the various designs. The results of these analyses, verified by shop tests, show that there is an apparent relationship between the load carried by a bucket or the total steam passed by it and the tendency to vibrate and the corresponding degree of fatigue suffered. Below a certain loading, there is apparent freedom from trouble, from which this company concludes at the present time that the corresponding fatigue, whenever present, is always within limits while for greater loadings the trouble percentages increase according to a fairly regular rule.

Out of the above relationships and with the aid of numerous production tests to determine coefficients, this company developed methods which enable it to proportion buckets with confidence that such fatigue stresses as may occur are well within the allowable limits. This company is of the opinion that the major difficulties have been overcome in present designs.

Features of Improvement

The features used to accomplish the above results comprise heavier and somewhat wider buckets for a given length with entrance and discharge edges rounded and last stages made sufficiently stiff to reduce as far as possible the use of tie wires. Where necessary tie wires of stronger construction and better design are used. With increased loadings, the steam pressures on buckets have been increasingly important and both buckets and dovetail connections have been designed to meet these increasingly severe conditions without increase of stress. The use of non-corrosive material is universal in the steam passages and the use of outside dovetails instead of inside dovetails is general for the intermediate as well as long buckets. Obstructions in exhaust chambers, such as ribs too near the last wheel, have been removed. Attention is paid to such details as correct edge thickness, correct fillet radii in root connection and suitable tenon connection at the tip. All of the above features are quantitatively evaluated and the proportioning is the result of systematic consideration.

During 1928 75 per cent of the troubles reported were discovered on inspection and only 25 per cent caused embarrassment in operation. Regular inspection and careful reporting of results by operating companies are important since only through such records of service can this company really know the true success of its designs.

STATEMENT BY THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO., EAST PITTSBURGH, PA.

The statement of this company is divided into three parts: The first deals with the handling of blading troubles, the second with the designing of blades for new equipment and the third with the standardizing of blading practice to the maximum degree.

Handling of Blading Troubles

The working instructions of this company include a definite set-up whereby every large turbine blading repair is questioned, even though this company is requested merely to furnish an order of blading material. A study is then made to determine, if possible, the cause of the difficulty.

If the cause of the trouble is obscure, or insufficient facts have been accumulated, specialists are sent to make a further study of the situation. After the available data bearing on any particular accident have been carefully analyzed, a definite recommendation is made. The Steam Service Department of this company has an Engineering Section which collects and analyzes turbine troubles of all kinds, including blading. The Engineering Department also has a special Blading Section, which makes the detailed analyses of blade stresses and cooperates with the Service Department in the making of recommendations regarding blading troubles. This company is equipped to give the owners of its equipment the benefit of its broad practical experience on blading matters. It is to this end that these groups of engineers are organized.

If a blade failure occurs in a turbine designed ten or fifteen years ago, the first desire is to know the history of the trouble, as, occasionally, blade damage occurs through difficulties directly associated with the operation of the equipment. When the history of the events immediately surrounding the accident are known samples of the broken blades, or photographs of the wreckage are desired for inspection.

Simultaneously an analysis is made of the blade stresses, based on the present methods of stress determination. In some cases, it is found that the blades in older turbines are stressed beyond what is now considered the conservative limit. This is usually borne out by the types of fractures found among the broken blades. In such instances this company uses blades of stronger materials, made to their modern standards, the cure having been invariably successful.

It is difficult to place in the hands of users a complete set of instructions for the examination and inspection of blading. This is mainly because the blading art is changing so rapidly. The best procedure with large turbine equipment is for the operating people to get in touch with the Service Department of this company.

Throttle valves continue to leak occasionally; distorted turbine spindles and cylinders are the natural result. A too-rapid starting under these conditions results in rubbed, and in some cases broken blades. Blade breakage that follows from a blade rub is sometimes very deceptive as to the character of the breaks, as these may resemble long-time progressive fractures.

An important operating consideration is the question of blades filling up with solid matter, usually in the form of solids that become more or less firmly cemented to the surface of the blades. The injection of water into turbines with badly filled-up blades has been resorted to, although in one case a badly bent spindle resulted. If, however, turbine blades become filled up to such an extent that the bending stresses or the end thrust on the rotor becomes dangerous, serious troubles may occur. Such possibilities warrant a careful daily check of the pressure distribution on all central station main units.

Regarding the inspection of turbines, there are usually certain localities that the manufacturer's engineers know from experience may be the source of cracks or breakage should dangerous blade vibration occur. For example, on Westinghouse standard rolled reaction blades, the first place to inspect is at the inlet edge at a distance above the spindle or cylinder about equal to the width of the blade. The probability of blade breakage at this point is reduced by the rounding of the blade edges. If the blades are overstressed, or if there is heavy vibration, cracks will start at this point and slowly progress across the blades. In our older turbines where we did not round the packing as much as we do at the present time, a careful examination should be made of the blades adjacent to the packing, as in cases where sharp packing is pressed against the surface of the blades, breakage may start at this point. This is avoided in modern blading by giving the packing a generous radius on the upper edges.

The lashing wire should be carefully examined for breakage. In older Westinghouse reaction turbines, lashing wire breakage, if it occurs at all, will usually be between the first and second blades at the trailing end of the group. In ordinary blades of low stress where the breakage is not frequent, the lashing wires can be resoldered. The important point to watch when this is done is the cleaning of the breaks, and this, incidentally, is the point where the workman usually falls down. A careless workman is liable to daub the joint over with flux and solder and think the job well done. If there are many breaks in a single row, then it may be desirable either to install new lashing wire, or possibly to fit in an additional wire, which has sometimes been done without removing the blades from the spindle or cylinder. In such cases, a milling rig is available, by means of which a wire can be set in from the edges of the blades and soldered in place, all of which can be done in the field.

Another question that frequently comes up in connection with older reaction turbines is that of clearances. This company has accumulated considerable knowledge with regard to the distortion of large cylinder and spindle structures, from which it has been concluded that some of their older turbines were shipped with insufficient clearance over the tips of the reaction blades. For this reason this company sometimes recommends that the clearances be increased.

Another question that frequently arises concerns the effect of increased blade or dummy clearances on efficiency. With their modern turbines, this company can supply users with a curve, showing the rate at which the overall efficiency is depreciated per 0.010 in. increase in clearance in each row of blades and for each individual dummy. These curves are worked out so that if, for example, in the fifth spindle row of a given turbine, the clearance is 0.020 in. greater than the original value, the overall depreciation in efficiency can be read from the curve. In the case of accidental blade rubs, the operating people can decide the commercial value of replacing any given row or a number of rows of blades and thus be better able to decide when such replacements should be made for reasons of increased clearance. These statements also apply to low pressure blades where the tips become eroded by the action of entrained moisture.

Another question that sometimes arises is the corrosion and erosion of steel blades in the low pressure zones of large turbines. This type of blade usually looks worse than it really is. Around the dewpoint, for example, there is what appears to be a quite erratic type of corrosion that will occur here and there on the blades on the outlet edges, as well as on the inlet edges. It is particularly evident in the shadows in the fluid stream cast by the lashing wires. In such cases this company usually views the eroded blades from three standpoints: The first is that of mechanical efficiency. If the corrosion or erosion has progressed in the dewpoint regions to a point where the lashing wires are badly cut or the silver soldering is undermined, or where the outlet or inlet edges have been carried away so as to cause rapid change of section, this company usually recommends replacing such blades with others of stainless steel.

Where the mechanical strength is not impaired, it is next usual to consider the effect of this erosion or corrosion on efficiency. If the profiled tips of reaction blades are carried away to the degree where the clearances are seriously increased, then this must be decided on its own merits, based on the rate of change of efficiency with increased clearance, which can be determined from the data which this company will gladly furnish. In the case of reaction blades, the effect of erosion and corrosion on blade form is seldom sufficient to affect the efficiency abnormally. As stated above, the blades may have an extremely bad appearance, while the form has not been altered to the degree where the efficiency is seriously impaired.

In the case of low pressure blades, erosion is usually at the inlet edge, being most severe in the region of the blade tips. In the last few rows there is seldom a serious attack on the outlet edges. The water wear of the inlet edges is seldom bad enough to warrant blade replacements.

Where 5 per cent nickel steel blades are used, this company has in many cases coated the inlet edges with silver solder after a year of service. Silver solder, while a relatively soft alloy, is highly resistant to the erosive effect found in the last few rows of large turbines. This seems to be an entirely satisfactory treatment to which this company fully subscribes.

Designing of Blades for New Equipment

Following are some of the developments that have aided toward the improvement of turbine blading reliability.

The rounding of blade edges seems to be an obvious thing to do. The fatigue resistance of turbine blades (measured by the number of vibrations required to produce failure in a number of types of blade-testing machines employed by this company) is increased in the ratio of about three to one by the simple expedient of rounding and polishing edges. This rounding of edges is now carefully carried out on all blades, large or small, whether they be for new equipment or for repairs.

The edges of the lashing wire holes in double-lashed blades are carefully rounded. Our fatigue-testing machine results have shown improvements from 25 to 50 per cent in the fatigue resistance from the adoption of this simple change in process.

The upper edges of the packing pieces employed with drawn and upset blades are carefully rounded.

Improved blading materials have accomplished as much as anything else toward the increased turbine blade reliability. The standard materials employed by this company are as follows:

(a) Impulse blades—5 per cent nickel steel.

(b) Rolled and drawn reaction blades for small turbines—manganese copper.

(c) Reaction blading—both rolled and forged—for large central station turbines—stainless steel.

(d) Low pressure reaction blading for intermediate sizes of machines with low blade speeds—5 per cent nickel steel.

It must not be assumed that where manganese copper is employed instead of stainless steel that these materials are used interchangeably. The stainless steel is ordinarily operated at stresses about fifty per cent in excess of those considered safe for the manganese copper. Where manganese copper is used, the factor of safety is just about as great as in cases where stainless steel is employed.

The metallurgical work in connection with the control of the quality of the raw material, as well as the maintaining of uniform process results, has advanced substantially during the past few years. Space permits only a brief mention of this work. Our most notable improvements have been in the accumulation of a greater knowledge of the properties of materials under high temperature, a more complete knowledge of their fatigue properties, and, particularly, a more complete knowledge of such factors as hot-shortness and solder-cracking.

The problem of solder-cracking is little understood. If, for example, a piece of 30 per cent nickel steel wire is held in a vise and heated to the ordinary silver-soldering temperature, it may bend easily without breaking. Another piece of the same wire is coated with flux and heated to the silver-soldering temperature, coated with silver solder, and, if an attempt is made to bend it while the coated rod is still at soldering temperature, it will break. The molten solder has what might be called a strong corrosive action in the intercrystalline structure at the soldering temperature. Solder-cracking makes many otherwise good materials totally unfit for use as turbine blades.

It is but natural that knowledge of blading design has increased in the direction of stress-analysis determinations. With present methods of stress analysis, this company is now able to explain many older failures that were hitherto thought anomalous. In general, reaction blade stresses can be divided into four classes, as follows:

(a) Those due to centrifugal force.
(b) Those due to pressure drop over a given row.
(c) Those due to the tangential reaction.
(d) Those resulting from the so-called eccentric loading.

Coming to the design of long, low pressure blades, this company believes one of the most important factors is the distribution of the mass of the blade so that when all forces acting on the blade are considered, it tends to stand radially and thereby insure a uniform load over the blade section. If, for example, a long, low pressure blade were designed so that the center of gravity of the base section was offset some appreciable amount from the center of gravity of the active portion of the blade, eccentric stresses would come into play that might result in overstressing and ultimate failure.

In long, low pressure blades, an improved arrangement of lashing is employed, in which the lashing wires pass through the center of gravity of the blade section, with a heavy integral reinforcement on the blade to prevent localized stresses.

In the design of turbine blading, one of the most important things is the elimination of obstructions in the blade path that would cause an intermittent pulsation, such as might be created by a gap between the stationary blades at the horizontal joints. Great care is taken to maintain a uniform spacing of the stationary blades.

Obstructions in the exhaust chambers, such as projecting ribs that have been placed too close to the last row of blades, may set up pressure fluctuations and cause blade failure. It is also considered undesirable to bleed a turbine from the lower half, thereby creating an alternating stress in a given row of blades. The above statements will show our general tendencies in the design of blades for new equipment.

Coming to the question of blade fastenings, it is believed that, in general, the experience of users is that blade fastenings are generally stronger than the active portions of the blades. It may be said that trouble with the equipment of this company due to failure of blade fastenings is almost unknown.

Blade Research

In connection with overcoming of troubles and designing new blades, it is, of course, a hardship to the industry that the form of turbine blade best suited to secure the maximum efficiency with regard to energy conversion is the weakest kind of structure mechanically. In other words, beams of a crescent section would not be adopted in the building of a skyscraper. Some improvements can be realized by so designing the sections that the sharp outlet edges shall not be the fibers most remote from the neutral axis of the moment of least inertia. The inlet edges can be thick and rounded without serious loss in efficiency, while the outlet edges of reaction blades must be made as thin as possible, consistent with safety.

In order to determine the relative strength of various blade sections, forms of sections, rounding of blade edges, rounding of lashing wires, etc., a number of blade-testing machines have been designed and built by this company, which have, in the past few years, given excellent methods of comparing the relative values of different blade constructions. This company has a so-called hammer-testing machine, in which grooved blocks which contain several rows of blades may be mounted in a swinging hammer. This hammer is thrown back and forth between two stationary anvil blocks, thus subjecting the blades to alternate shocks, first in one direction and then in the other. The hammer is so adjusted that the fractures will take place between 20,000 and 400,000 blows. The fractures occur at the same points of weakness found in actual turbines. They progress, generally, in the same manner. The texture of the breaks

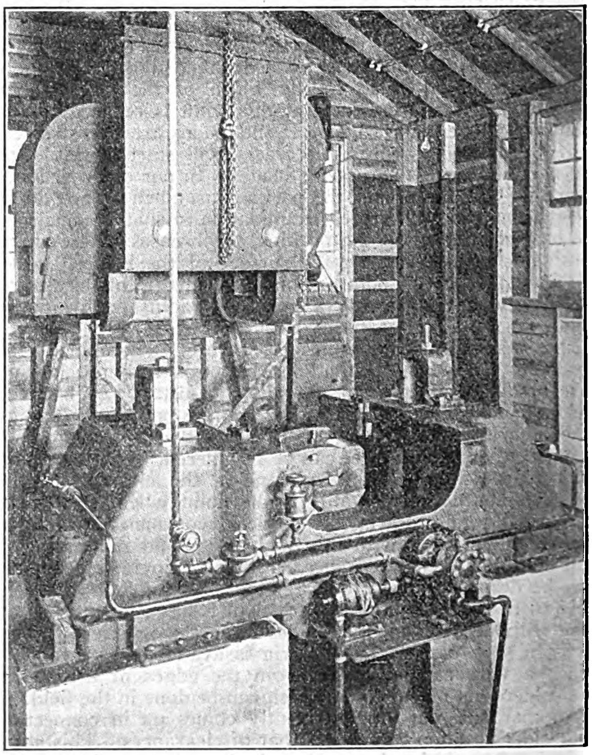

FIG. 9—TURBINE BLADE, HAMMER TESTING MACHINE —WESTINGHOUSE ELECTRIC & MFG. CO.

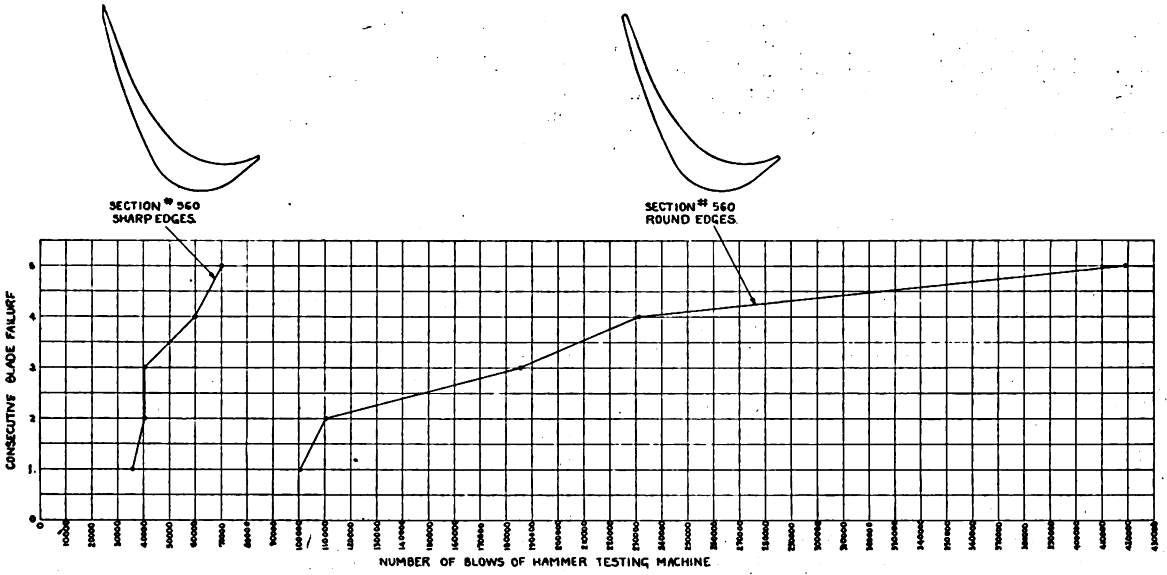

FIG. 10—IMPROVEMENT IN TURBINE BLADE FATIGUE RESISTANCE BY ROUNDING EDGES—WESTINGHOUSE ELECTRIC & MFG. CO.

resembles the breaks found in service. Many valuable results have been obtained from the hammer-testing machine, shown in Fig. 9.

A comparison of blades with sharp and rounded edges is shown in Fig. 10.

The so-called crank-testing machine is shown in Fig. 11. In this machine, groups of blades are held in moving cross-heads, so that their bases are moved rapidly back and forth, thereby stressing the assembled blade groups by reason of the inertia forces. The main advantage of the crank-testing machine is that we can obtain results in a much shorter space of time than with the hammer-testing machine.

A rotating-beam-testing machine which is used for testing single blades is shown in Fig. 12. The blade is held at its base by a heavy anvil block, while the outer end is held by an eccentric, which is, in turn, mounted on the end of a motor shaft. Many studies have been made with this equipment of certain blade types, particularly with respect to local reinforcing, rounding of lashing wire holes and allied problems.

A check is made of the natural frequency of a group of blades in every row in each large central station turbine shipped from the factory. This is done, first, to see that the frequencies of the longer blades do not agree with low multiples of the rotational frequency of the turbine rotor. The blade frequencies are determined with the aid of an oscillograph with a pick-up coil held adjacent to the blade surface, or, in case of non-ferrous blades, close to a small armature temporarily silver-soldered to one of the blade tips. The majority of this work is for statistical purposes, the main object being that the data shall be available for the study of obscure field breakage, should it take place.

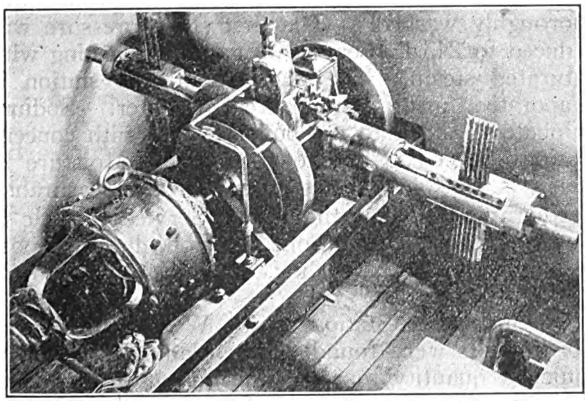

FIG. 11—TURBINE BLADE, CRANK TESTING MACHINE—WESTINGHOUSE ELECTRIC & MFG. CO.

A history is maintained of each individual large turbine, in which the various stresses are segregated, the natural frequencies of the lashed blade are tabulated, etc., in connection with which blade troubles may be studied.

Standardization of Blading Practice

In the preceding paragraphs, certain important changes in process have been mentioned. Such alterations are so important that they are being introduced as quickly as possible. Wherever possible, changes that lead to an increase of reliability are made retroactive and are made effective as far back as possible for repair work. In this connection, users may find an increase in prices in certain cases of repair blading. In most instances, they are caused by the introduction of modern blading standards for older equipment. Such recommendations are in accord with the general program of this company to serve turbine users in the best way, in line with the latest blading practice.

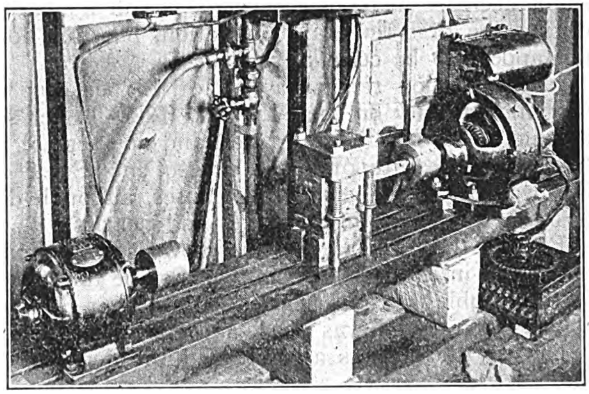

FIG. 12—TURBINE BLADE, ROTATING BEAM TESTING MACHINE, WESTINGHOUSE ELECTRIC & MFG. CO.

It is to be regretted that the turbine blading situation cannot be treated in a general way and characteristic information be placed in the hands of users that will apply to any case. This company is glad to place at the disposal of users any knowledge in its possession, and, as it is pointed out in the preceding comments, it has endeavored to do this whenever direct questions come to it from the operating companies. This policy has led to a substantial reduction in blading troubles; in fact, it is not unfair to state that, in the course of the next few years, blading troubles should be practically eliminated other than the ordinary corrosion and erosion that may still exist with the best materials yet obtainable.

DEPOSITS IN TURBINE BLADING

In response to a questionnaire concerning salt deposits in turbine blading, twelve companies reported troubles encountered in operation because deposits formed in the high pressure stages of their turbines. Other companies reported deposits in the low pressure stages, but this did not noticeably affect operation.

From the replies received, no method of cleaning blading which would be universally applicable was evolved. The information presented should be helpful in suggesting a method of approach when these troubles are encountered. The details for each problem must be worked out separately after due study of the installation and analysis of the salts deposited.

The deposit of salts in the high pressure stages of turbines must be considered seriously if it affects the capacity of the machine. This may result in increased load on blades or diaphragms, as well as adversely affecting the economy.

Deposits were encountered regardless of the operating pressures. The companies reporting trouble operated at pressures from 200 to 1200 lb. per sq. in. gage.

At Lakeside Station troubles with the 1200 lb. per sq. in. installation were partially corrected when the boiler concentrations were reduced to below 500 p.p.m. and the baffling in the drum improved. A slight decrease in turbine capacity is still noticeable during the first few days' operation, but this does not appear to be cumulative.

Edgar Station reports a loss of 15 per cent in carrying capacity on the 3150 kw., 1200 lb. per sq. in. unit in 26 months' operation and an increase in first stage pressure of 70 lb. per sq. in. Some of this was possibly due to other causes, although deposits are reported in all stages and nozzles.

Both of the foregoing stations now use tri-sodium phosphate in the feed water. During the time most of the trouble was experienced at the Edgar Station, a boiler compound was used, and considerable corrosion of the buckets accompanied the deposits of these salts.

Columbia Station of the Union Gas & Electric Co. showed a drop in carrying capacity from 44,000 kw. to 37,000 kw. in 45 days' operation. The throttle and first stage steam pressures were the same in both cases. The high pressure turbine outlet pressure dropped from 105 to 85 lb. per sq. in. gage, indicating a deposit in the high pressure stages at temperatures probably in excess of 500 deg. fahr.

At Philo Station of the Ohio Power Co. turbines No. 1 and 2 will deliver the rated capacity of 40,000 kw. after the machines are restored to service following an idle week-end. With a few days' operation the capacity decreases to 38,000 kw., which cannot be exceeded until the machine is again taken out of service for the week-end.

This is similar to reports from other plants, where a minor loss of capacity follows short periods of operation which is restored after an outage over the week-end. It is probable that the cooling down of the machine under these conditions either cracks off the scale or the initial charge of steam to roll the turbine carries sufficient moisture or is cooled below saturation and removes, at least, the load affecting portion of the deposit.

Reheat Boilers Source of Troubles

At both Columbia and Philo Station the reheat boilers are believed to be one source of these troubles. Water at Columbia was treated with lime, soda ash, ferrous sulphate and di-sodium phosphate with a concentration of approximately 900 p.p.m. maintained in the drums. Evaporators have recently been installed, but operating results are not yet available.

Crawford Avenue Station of the Commonwealth Edison Co. reports a loss of capacity as high as 25 per cent, requiring higher inlet steam pressures to carry a given load. This station formerly used Zeolite treated make-up, but now uses evaporated make-up. The concentrations are less, but the deposits still occur. Some phosphates are shown in the boiler water analyses submitted.

At Trinidad Station of the Texas Power & Light Co., the first stage pressure of the turbine increased during eight months' operation at 20,000 kw. load from 231 lb. per sq. in. gage to 289 lb. per sq. in. gage. The former pressure was obtained after the period of annual inspection when the rotor was thoroughly washed. The first stage pressure was reduced to 243 lb. per sq. in. gage by washing with saturated steam. The make-up at this station is evaporated, using Zeolite treated water. Sodium sulphate is added to the boiler drums with concentrations carried at 300 to 400 p.p.m. Moisture in steam is very low, being practically unmeasurable.

Kearny Station of the Public Service Electric & Gas Co. reports that on one occasion, due to deposits of salt, only 35,000 kw. could be carried on a 40,000 kw. unit.

At Springdale Station of the West Penn Power Co. deposits were found on the blading, but not in sufficient quantity to affect the output of the unit. Reduction in boiler concentrations from 1350 p.p.m. to about 600 p.p.m. has practically eliminated the deposit.

Kearny and Springdale Stations use tri-sodium phosphate with other chemicals for water treatment. Concentrations up to 2500 p.p.m. are carried at Kearny with boiler ratings maintained below 200 per cent. New drum baffling was also installed.

Rochester Gas & Electric Co., Station No. 3, operates on steam at 205 lb. per sq. in. gage and 480 deg. fahr. total temperature. The turbines are washed whenever a rise in the first stage pressure becomes evident.

Five stations report methods used in washing the turbines. Rochester Station No. 3 uses water introduced just ahead of the strainer through a ½ in. line when the machine is taken out of service. When a speed of 150 to 200 r.p.m. is reached, the throttle is cracked and the water admitted for approximately six minutes. During this operation the speed is held below 500 r.p.m. It is stated that this method is effective and has caused no apparent harm to the turbines. These are essentially low pressure, low temperature units from 7500 to 15,000 kw. capacity. The water admitted to the turbine cannot cause as great a change in temperature as would be the case with machines operating at high pressure and temperature.

Kearny used a similar method, taking care to avoid too rapid change in steam temperature.

Columbia Station uses saturated steam from a low pressure bleed point of another turbine, completely desuperheating the steam used by water jacketing the bleed steam line. The steam is admitted beyond the throttle valve with the turbine at rest. Circulation is obtained by blocking the drain traps connected to the high pressure cylinder, allowing them to discharge into the main condenser where a slight vacuum is maintained. This operation is continued until the turbine is returned to service.

Washing with Saturated Steam

At Crawford Avenue washing is done with saturated steam. Water from the boiler feed system is injected into the main steam lead just before the throttle valve at a slow rate until the steam temperature gradually being reduced reaches the saturation temperature. The temperature is held at saturation for a short time; the water is then gradually decreased and the temperature allowed to return to normal.

Trinidad Station uses saturated and wet steam to do the washing. Saturation is obtained by injecting hot feed water into the steam line through a high pressure spray nozzle. The effects of washing were indicated by conductivity tests of the condensate and operation discontinued when normal readings were obtained.

The Committee is unable to prove conclusively that any particular system of boiler water treatment or the presence of any particular chemicals is responsible for the trouble encountered. Some salts, of course, have a greater tendency to induce priming than others. There were installations where the use of certain chemicals apparently contributed to the trouble, but conflicting cases would arise where similar water treating methods were used, but no deposits were reported. Other factors not revealed by the reports received evidently contributed to this condition.

The troubles appear to increase with boiler drum concentrations and with boiler outputs. Soluble sodium salts formed a large percentage of the deposits analyzed, although in some cases the opposite was true and the soluble salts were a relatively small percentage of the total. In some instances appreciable proportions of sodium hydrate were found in deposits. The chemist for one company has pointed out that the melting point of sodium hydrate is 604 deg. fahr. Therefore, sodium hydrate might be carried over in the steam in a melted condition and readily become attached to or settle out on the blading at temperatures below 600 deg. fahr. It was expected, however, that this sodium hydrate would be gradually changed to sodium carbonate due to the action of carbon dioxide, which is undoubtedly present in the steam. The sodium hydrate in certain temperature zones makes an excellent cementing medium for attaching other salts to the blades. Even where the proportion of soluble salts is low it is believed that washing with saturated steam will weaken the structures so that the salts will fall off.

TURBINE MAINTENANCE AND CARRYING OF SPARE PARTS

Fifty-one replies were received from operating companies in connection with the questionnaire covering turbine maintenance and carrying of spare parts. Replies covered the practice of 58 power stations. The number of generating units included are in excess of 179, and represent a total capacity of more than 5,100,000 kw.

Spare Parts

All companies maintain a stock of some spare parts. One company reports that they are not justified in maintaining a supply of spare parts due to insurance covering breakdowns, and two companies report they are not justified in carrying the supply they have on hand. One company reports purchase of 1/3 set of stator coils after installation, and 2/3 after five years. Table XIII shows the practice of the reporting companies with regard to kind of spare parts carried in stock for their machines. Table XIV shows the manner in which spare parts are acquired.

Major Inspections

The companies are classified in Table XV according to the rules whereby the periods between major inspections are determined. Several companies report that time of inspection is based on both the elapsed time and hours in service.

TABLE XIII

TURBO-GENERATOR SPARE PARTS STOCKED BY OPERATING COMPANIES.

Name of Part	No. of Companies
Turbine spindles	4
Turbine blades	4
Main bearings	37
Thrust bearings	39
Throttle valve parts	26
Governor parts	46
Oil pump parts	39
Complete generators	2
Portion of generator stator winding	8

Replies with regard to the time necessary for an inspection of the vital running parts of the turbine indicate that the majority of companies interpreted this question as referring to the time required for a complete inspection of the unit, which varied in most cases from two to three weeks. One company reports it can make inspection of the vital running parts of its 60,000 kw. units and reassemble in 48 hours. Another reports 12 hours for a 22,500 kw. unit, and 8 hours for a 15,000 kw. unit. Other companies report 72 hours for the same work. It is not known to what extent the times reported represent periods when actual work was in progress.

TURBO-GENERATOR UNITS—METHOD OF ACQUIRING SPARE PARTS.

Method	No. of Companies
Inclusion of spare parts in the contract for unit	13
Spare parts purchased separately and after installation of unit	31
Arrangement with neighboring utility to carry a common supply of spare parts	4
Common supply of spare parts carried by associated companies	3
No arrangement with neighboring companies to carry a common supply of spare parts	40

TABLE XV

TURBO-GENERATOR UNITS—PERIOD BETWEEN GENERAL INSPECTIONS.

Condition	No. of Companies
Inspections based on elapsed time	35
Units inspected every year	27
Units inspected every 1 to 1½ years	1
Units inspected every 2 years	6
Units inspected every 3 years	1
Inspections based on unit service hours	9
Inspections based on no definite time schedule	2

Repair and Inspection Personnel

In general the companies use their own employees to make inspections and repairs. Five companies do not use their own employees for this work and apparently depend on the manufacturer. All companies, with the exception of one, engage a factory representative to supervise or be present while general inspections and repairs are in progress. One company reports that it does not use a factory representative in connection with general inspection and repairs, while several other companies only use factory assistance in connection with blade renewals or turbine and generator repairs of a special nature.

Performance Tests

The majority of companies depend on routine tests and station instrument records to determine the condition of their generating units. Eight companies report making tests following repairs which would effect turbine economy. Some companies conduct tests before and after repairs are made.

STEAM TURBINES FOR AUXILIARY DRIVES

The Committee reviewed the operation and maintenance of turbines for auxiliary drives for 1926, 1927 and 1928. Very few units recently installed by operating companies were reported upon. The information received did not disclose any operating experiences that were essentially new, but largely reviewed the operation and maintenance of this apparatus as reported in the 1927 report.

TESTS OF TURBO-GENERATOR UNITS

Reports of tests on turbo-generator units were received from member companies. These tests of 6000 to 60,000 kw. units were made under conditions that either represent normal operation or operation under special conditions to facilitate comparison with guarantees, or to observe the influence of certain operating conditions on unit economy.

With the advent of the regenerative cycle, the factors that influence economy became more numerous and testing of the unit became more complex. To determine the steam consumption of unit when steam is extracted from the turbine by weighing all the condensate is a problem that is easily solved only when the extraction stages are few and the bleed condensate drains to the condenser. Invariably, on the tests reported, only that part of the bleed condensate is weighed that drains to the condenser; the remainder of the bleed steam is calculated from the heat balance of the extraction heater. In some cases the efficiency of the extraction heater is separately determined and applied to heat balance calculations.

Table XVI shows the pertinent data for the turbines on which tests are reported, also the conditions of operation with respect to steam extracted.

Tests in previous reports represent straight con-

*Rating of Turbo-Generator in kv-a.

densing operation. Some of the tests in this report were made on units operating on the regenerative cycle, with data presented on the performance of the extraction heaters as well as the turbine and generator. Data are also furnished for the same units when operated straight condensing and on the regenerative cycle to disclose the thermal gain effected by extracting steam for feed water heating. The difference in economy of the same unit when operated straight condensing and when steam is extracted, however, may not equal the difference in economy for two similar machines, one designed to operate straight condensing and the other designed for extraction operation.

Tests are also presented that show the effect of changes in the exhaust vacua on the economy of a unit when operated on the regenerative cycle, also the effect on economy when bleed steam is used to evaporate make-up and the vapor returned for feed water heating.

TURBO-GENERATOR TEST NO. 1

A series of tests was made to determine the performance of this unit when no steam is extracted from the turbine, also when steam is extracted from two stages of the turbine for feed water heating. Tests were made during May, 1926.

Test Apparatus Data

Turbine: Tandem compound, Parsons type, Westinghouse machine rated at 50,000 kw., exhausting into a 70,000 sq. ft. Westinghouse radial flow, 2 pass, surface condenser. The machine is designed to operate with throttle steam at 265 lb. per sq. in. gage and 200 deg. fahr. superheat with the exhaust pressure at 1.0 in. of mercury abs. The turbine is provided with three governor control valves. When the unit is operated at 80 per cent power factor, and the turbine is supplied with steam at guarantee conditions, with no steam extracted, the primary control valve is fully open at 36,000 kw., the secondary valve at 45,000 kw. and the tertiary valve at 50,000 kw. During normal operation, steam is extracted from two points for feed water heating. The high pressure heater is supplied with bleed steam from the exhaust end of the high pressure cylinder. The low pressure heater is supplied with bleed steam from the center section of the semi-double flow low pressure cylinder.

Generator: Westinghouse, 62,500 kv-a., 80 per cent power factor, 60-cycle, 3-phase, Y-connected, 13,800 volt alternator with a 225 kw., 250 volt direct connected exciter.

The two extraction heaters are Wheeler closed type with horizontal return tubes arranged for four-pass flow of feed water passing through the heater. Each heater contains 3500 sq. ft. of heating surface made up of three-quarter inch, No. 16 B.W.G. seamless drawn copper tubes.

Method of Conducting Test

Eight 2-hr. runs were made with the turbine operating straight condensing. A similar number of runs was made with steam extracted at two points for feed water heating.

The generator output was measured at the generator terminals by the 3 wattmeter method with instruments read at minute intervals. A calibrated current transformer was inserted in each phase at the neutral and a calibrated potential transformer installed beween the neutral and each phase terminal.

During the non-bleed runs, the stop valve and hydraulic valves in the high and low pressure bleed steam lines were closed. The steam consumption of the unit was obtained by weighing the condensate from the main condenser and correcting this weight for water supplied to the low pressure turbine seals.

During the extraction tests the unit operated with its feed water system separated from the other units in the station. The high pressure bleed condensate discharged into the low pressure heater. The drains from the low pressure heater, which include the bleed condensate from the low pressure heater and the bleed condensate from the high pressure heater, were returned to the system by pumping into the boiler feed suction. The condensate from the main unit condenser, which includes the steam exhausted by the turbine and water supplied to the low pressure turbine seals, was obtained by weighing. The bleed condensate was not weighed on these tests. The quantity of bleed steam was calculated, based on observed data and heater efficiency curves that were previously determined from heat balance tests when condensate from bleeder heaters was weighed.

The quantity of feed water passing through the extraction heaters was equal to the steam supplied to the turbine and the water supplied to the low pressure turbine seals.

Results

A summary of the results of the test made with the turbine operating straight condensing is shown in Table XVII. The heat consumption of this unit under test condition corrected to guarantee and the performance guaranteed for the unit are graphically shown in Fig. 13.

The results of the tests with both extraction heaters in service are summarized in Table XVIII. The gross heat consumption is based on heat consumed by the turbine and the generator output. The net heat consumption is based on the heat consumption of the turbine, including steam jet air pumps and the generator output after the power used by the main condensate and the condenser circulating pumps has been deducted.

The curves in Fig. 14 show the heat consumption on both

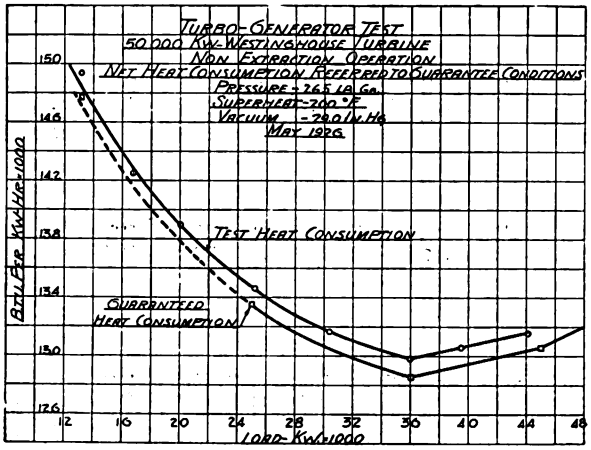

FIG. 13—NET HEAT CONSUMPTION, NO STEAM EXTRACTED FROM TURBINE—TURBO-GENERATOR TEST No. 1.

gross and net kw. output basis with steam extracted at two points for feed water heating. In Fig. 15 the relation is shown between the steam supplied to the unit, the steam exhausted to the condenser, and the steam extracted, both total and segregated, for the high and low pressure bleed points.

To facilitate comparison of the performance of the same unit under bleeding and non-bleeding operation, the steam flow at the throttle, the water rate and the thermal efficiency of the unit are shown respectively in Fig. 16, 17 and 18 for both conditions of operation.

TURBO-GENERATOR TEST No. 2

These tests were made on a turbo-generator unit to determine the economy of the unit when operating on the regenerative cycle, also to investigate the performance of the extraction heaters. Tests were made during November, 1927.

Test Apparatus Data

Turbine: Westinghouse Electric & Manufacturing Co.; 1800 r.p.m.; single cylinder with multi-exhaust blading, exhausting into a Westinghouse Electric & Manufacturing Co., 50,000 sq. ft. surface condenser.

Generator: Westinghouse Electric & Manufacturing Co.; 43,750 kv-a.; 80 per cent power factor; 13,800 volts; 3-phase; 60 cycle; 1800 r.p.m.

Exciter: Westinghouse Electric & Manufacturing Co.; d-c.; direct connected; 165 kw.; 250 volts; 1800 r.p.m.

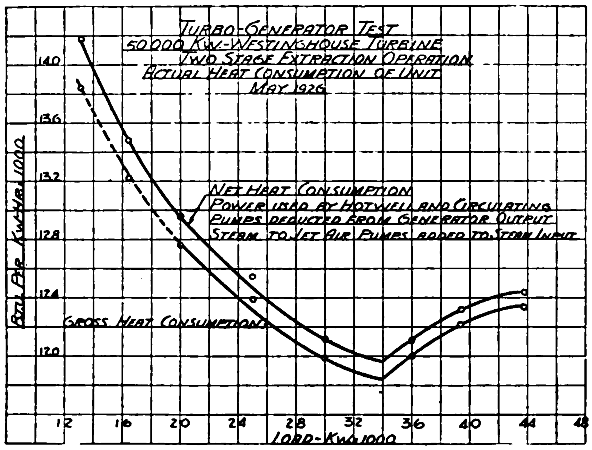

FIG. 14—GROSS AND NET HEAT CONSUMPTION, STEAM EXTRACTED AT TWO STAGES OF THE TURBINE—TURBO-GENERATOR TEST No. 1.

Generator air cooler: Griscom-Russell Co.; U-fin cooler; maximum working pressure, 50 lb. per sq. in. gage.

Low pressure closed heater: Griscom-Russell Co.; condenser type; four pass; maximum working pressure, steam, 50 lb. per sq. in. gage; water, 100 lb. per sq. in. gage; heating surface, 1700 sq. ft.; ⅝-in. O.D., No. 18 B.W.G., seamless drawn Admiralty tubes. Steam supplied to heater from fourth extraction stage.

Pre-cooler: Cochrane Co.; single pass, surface condenser; capacity, 400,000 to 1,000,000 lb. per hr.; heating surface, 150 sq. ft.; ⅝-in. O.D., No. 18 B.W.G. tubes. The pre-cooler is a surface condenser on the vent of the open heater.

Barometric condenser: Cochrane Co.; duplex nozzle jet heater; capacity, 500,000 to 1,000,000 lb. per. hr.

Open heater: Cochrane Co.; metering heater; deaerating type; capacity, 400,000 to 1,000,000 lb. per hr.; working pressure, 5 lb. per sq. in. gage.

Intermediate pressure heater: Griscom-Russell Co.; condenser type; four pass; maximum working pressure, steam, 65 lb. per sq. in. gage; water, 500 lb. per sq. in. gage; heating surface, 2000 sq. ft.; ⅝-in. O.D., No. 16 B.W.G., seamless drawn Admiralty tubes.

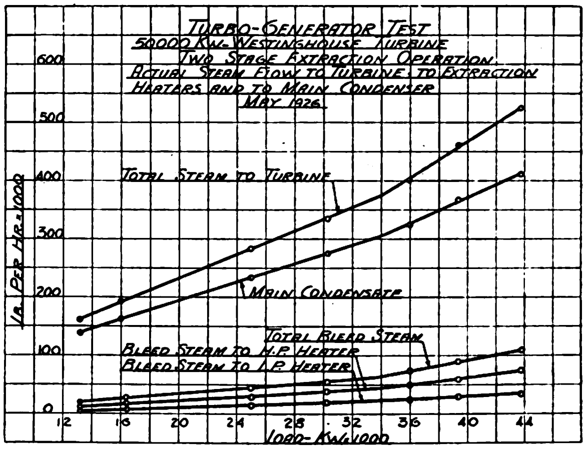

FIG. 15—STEAM DISTRIBUTION, STEAM EXTRACTED AT TWO STAGES OF THE TURBINE—TURBO-GENERATOR TEST No. 1.

High pressure heater: Griscom-Russell Co.; four pass; condenser type; maximum working pressure, steam, 170 lb. per sq. in. gage; water, 500 lb. per sq. in. gage; heating surface, 2000 sq. ft.; ⅝-in. O.D., No. 16 B.W.G., seamless drawn Admiralty tubes.

Method of Conducting Test

Tests were made at all loads under normal conditions of steam pressure and vacuum, no air being admitted to the condenser or air pumps.

Steam was extracted from four stages of the turbine for feed water heating.

The condensate from the hotwell of the main condenser was pumped through the low pressure closed heater to the weigh tanks. A test pump returned the condensate from the test storage tank to the condensate system at the pre-cooler, passing through the pre-cooler and the barometric condenser to the open heater. The open heater discharged to the boiler feed pumps. The condensate at feed water pressure passed through the intermediate pressure closed heater and high pressure closed heater to the boilers. The bleed condensate from the low pressure closed heater was drained to the hotwell of the main condenser. The bleed condensate from the intermediate and high pressure closed heaters was drained to the open heater.

The quantity of water passing through the low pressure heater and the vent condenser which is equal to the steam condensed by the main condenser and the bleed condensate from the low pressure closed heater was weighed on the

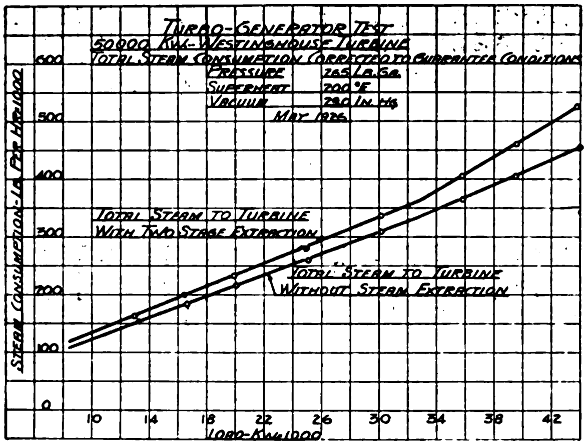

FIG. 16—STEAM TO TURBINE, WITH AND WITHOUT TWO STAGE EXTRACTION—TURBO-GENERATOR TEST NO. 1.

test weigh scales. The water supplied to all the other heaters was computed.

No corrections were necessary for seal water used. The high and low pressure seals of the main turbine and the condensate pump seals were supplied with condensate from the discharge of main condensate pump and recirculated in the system.

The kilowatt load was obtained from the switchboard polyphase watt-hour meter on which a high speed register had been installed. The watt-hour meter was adjusted and checked previous to the test and rechecked after the test, the calculations showing no corrections were to be applied for meter calibrations. The generator net output was corrected for phase angle and ratio of transformation of the instrument transformers used.

A chemical analysis of condensate and river water showed no condenser leakage.

The total steam consumption of the turbine was obtained by adding the weighed condensate and the calculated steam extracted from those stages of the turbine which have drains entering the system after the weigh tanks.

The bleeder steam was computed from heat equations involving the total heat in the steam at the heater inlet, the heat of the liquid of the bleed condensate, the weighed or computed water flow to the heater and temperature rise of water passing through the heater. The quality of the bleed steam to the low pressure closed heater was determined from the expansion curves of the turbine.

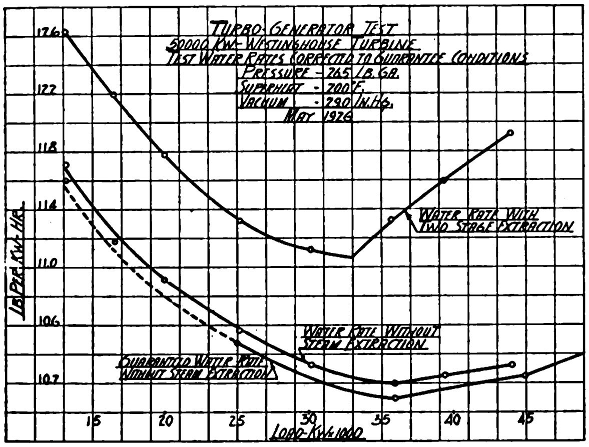

FIG. 17—WATER RATE WITH AND WITHOUT STEAM EXTRACTED AT TWO STAGES OF THE TURBINE—TURBO-GENERATOR TEST NO. 1.

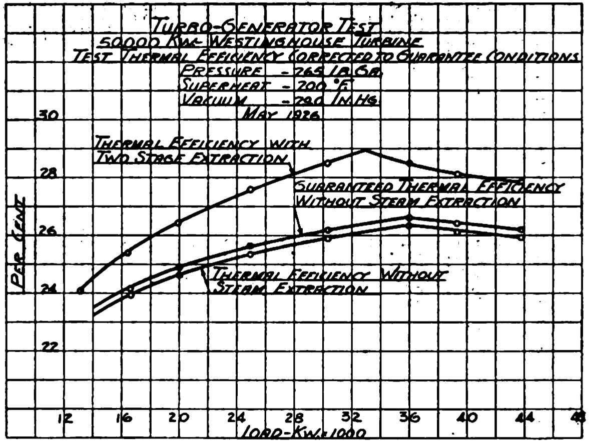

FIG. 18—THERMAL EFFICIENCY, WITH AND WITHOUT STEAM EXTRACTED AT TWO STAGES OF THE TURBINE—TURBO-GENERATOR TEST NO. 1.

Results

A summary of the test results with the turbine operating on the regenerative cycle with detailed data on the performance of the extraction feed water heaters and the auxiliary heaters entering into the heat balance of the unit is presented in Table XIX.

The steam superheat at the third extraction stage is effected by the high temperature steam from the balancing piston. The temperature at the outlet of the open heater is kept at approximately 215 deg. fahr. To maintain proper heat balance more or less steam is bled from the third extraction stage to the barometric condenser. This explains the wide variation in the bleed steam to the barometric condenser as shown on run F.

The generator heat losses were not recovered, river water being used to cool the air in the closed generator air cooling system.

The net heat consumption and the thermal efficiency of this unit are graphically presented in Fig. 19.

TURBO-GENERATOR TEST NO. 3

A series of tests was made on a Westinghouse turbo-generator unit to check the performance when operating on the regenerative cycle, also to investigate the performance of the extraction heaters. This unit rated at 52,500 kv-a.

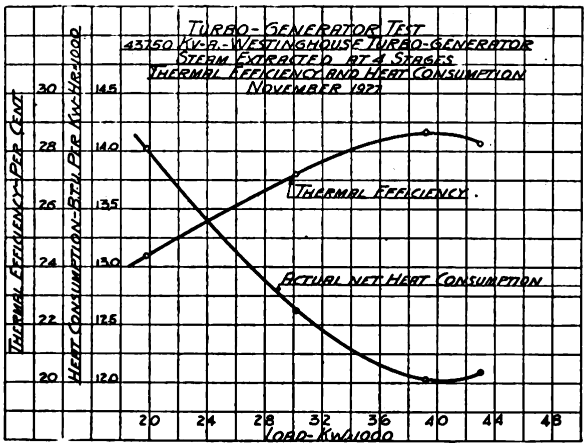

FIG. 19—THERMAL EFFICIENCY AND HEAT CONSUMPTION, STEAM EXTRACTED AT FOUR STAGES OF THE TURBINE—TURBO-GENERATOR TEST NO. 2.

at 90 per cent power factor, operating at 1800 r.p.m., is provided with four extraction nozzles that supply steam to heat feed water. The tests were made in June, 1928.

The extraction heaters for this unit are identical with the extraction heating equipment described for the unit under turbo-generator test No. 2. The Westinghouse single cylinder, multi-exhaust type turbine is also the same in size. These turbo-generator units differ by the higher connected generator capacity of the unit on which this test was made.

The method of conducting this test and computing the results is similar to that reported under turbo-generator test No. 2.

This test was made under normal unit conditions.

Test results, presented in Table XX, show the performance of the unit with steam extracted at four stages for feed water heating, with the exhaust vacuum at approximately 28.5 in. of mercury. Results of turbo-generator Test No. 2 show the performance of a similar installation, but with the turbine exhaust vacuum at approximately 28.0 in. of mercury.

Fig. 20 shows the actual heat consumption and thermal efficiency of the unit when operating on the regenerative cycle.

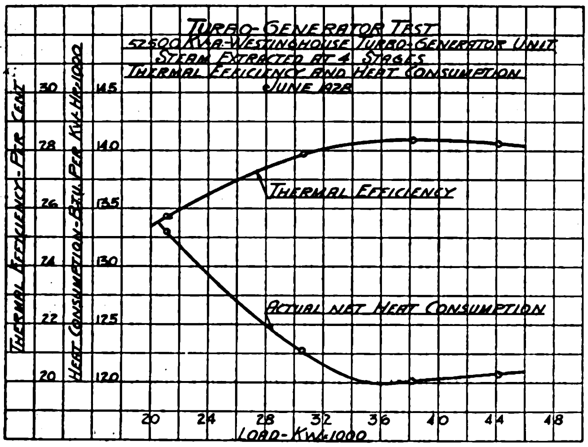

FIG. 20—THERMAL EFFICIENCY AND HEAT CONSUMPTION, STEAM EXTRACTED AT FOUR STAGES OF THE TURBINE—TURBO-GENERATOR TEST NO. 3.

TURBO-GENERATOR TEST NO. 4

The object of this test was to determine the performance of the turbo-generator unit when operating with steam extracted from two stages of the turbine and to compare this performance with the guarantee. Tests made in December, 1928.

Test Apparatus Data

The turbo-generator unit is a single cylinder, impulse-reaction, 1800 r.p.m. unit manufactured by Westinghouse Electric & Manufacturing Co., with rated capacity of 60,000 kw. at 85 per cent power factor. The turbine is provided with four extraction nozzles and operates with steam at 290 lb. per sq. in. gage and 700 deg. fahr. total temperature. This is the first single cylinder machine of its size constructed by this company.

Method of Conducting Tests

The unit was operated with steam extracted from the two lower stages over the load range of 15,000 to 58,000 kw. Two three-hour runs were made at the contract point of about 49,000 kw. which corresponds to the load carried by the primary and secondary valves. All other tests were of two hours duration with a total of nine tests made with the extraction heaters in service.

The steam consumption of the turbine was determined by weighing the condensate. The scales were checked before the tests with standard weights, the errors found were well within the A. S. M. E. test code requirements and scale readings were used without calibration corrections. The bonnets of the gate valves at the tank discharges were provided with bleeder lines for frequent checking for condensate that might escape. They were found tight at all times.

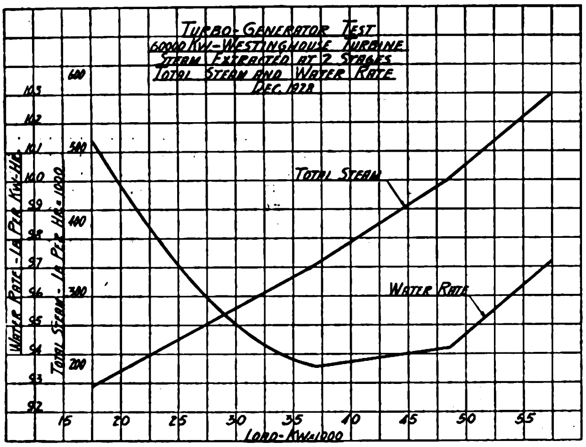

FIG. 21—TOTAL STEAM AND WATER RATE, STEAM EXTRACTED AT TWO STAGES OF THE TURBINE—TURBO-GENERATOR TEST NO. 4.

The electrical output was measured with special calibrated indicating instruments. The power factor was held as close as possible at 85 per cent.

All steam pressures were measured with absolute pressure gages located at the exhaust connection between the turbine and condenser. The calculated results were based on an average of these pressures.

The steam temperature at the throttle was measured by calibrated engraved stem mercury thermometers. The exhaust temperature was measured with engraved stem thermometers inserted through rubber stoppers placed in openings at opposite sides of the exhaust connection, between the turbine and condenser.

Other significant data on the turbine condenser and heaters were taken with either special test instruments or with calibrated commercial instruments.

Results

The performance of this turbo-generator unit is graphically shown in Fig. 21 and 22. A condensed summary of results is presented in Table XXI. The guaranteed performance is also tabulated to facilitate comparison of expected and actual performance.

TURBO-GENERATOR TEST NO. 5

This series of tests made in January, 1928, on a turbo-generator unit to check its performance when no steam is extracted from the turbine with the turbine exhaust vacua at 28.5 and 29.0 in. of mercury.

Test Apparatus Data

Turbine: Westinghouse Electric & Manufacturing Co.; 1800 r.p.m.; single cylinder type with multi-exhaust blading, exhausting into a Westinghouse Electric & Manufacturing Co. 50,000 sq. ft. surface condenser.

Generator: Westinghouse Electric & Manufacturing Co.; 43,750 kv-a., 80 per cent power factor; 13,800 volts, 3-phase, 60 cycle, 1800 r.p.m.

Exciter: Westinghouse Electric & Manufacturing Co.; d-c.; direct connected; 165 kw.; 250 volts; 1800 r.p.m.

Method of Conducting Tests

Tests were made at loads ranging between 16,000. and 43,000 kw. with the exhaust vacua held constant at 29.0 and 28.5 in. of mercury respectively. All runs were of three hour duration.

The turbine was operated without extracting steam. Pressure was maintained at 325 lb. per sq. in. gage by throttling the main throttle valve.

The kilowatt load was obtained from the switchboard polyphase wattmeter on which a high speed register was installed. The watthour meter was adjusted and checked previous to the test and rechecked after the test, the calibration showing no corrections to be applied to the meter. The generator net output was corrected for phase-angle and ratio of transformation of instrument transformers.

The steam consumption of the turbine was obtained by weighing the condensate, correction being made for hotwell level, condenser leakage and condensate from steam jet air pump whenever the pump was used. The high and low pressure seals of the main turbine and the condensate pump seals were supplied with condensate taken from the discharge of condensate pump. The weighing scales were calibrated previous to the test.

Tests were made on each run for condenser leakage. Chemical titrations were made for salt content in the river water and condensate from the condenser. The vacuum was regulated by admitting air at the turbine exhaust.

Computations

The steam consumption was corrected to guarantee conditions of 325 lb. per sq. in. gage and 271 deg. fahr. superheat. A 1 per cent correction is allowed for a 25 lb. per sq. in. variation in steam pressure and 1 per cent for each 15 deg. fahr. variation of superheat at the throttle.

Results

The results of the tests are shown in Table XXII and XXIII with the total steam to the unit, and the water rate and the efficiencies are shown graphically in Fig. 23 and 24.

This series of tests in which no steam was extracted from the turbine can be compared to the operation of the same unit when steam was extracted at 4 stages of the turbine. The latter results are reported under Turbo-Generator Test No. 2.

TURBO-GENERATOR TEST NO. 6

The object of tests made during April, 1928, was to determine the economy of the turbo-generator unit at 1, 1½ and 2 in. of mercury back pressure, with steam extracted at four stages for feed water heating.

Test Apparatus Data

Turbine: General Electric Co.; 50,000 kw.; 1800 r.p.m.; exhausting into a Worthington, two-pass, concentric shell, 56,000 sq. ft., surface condenser.

Generator: General Electric Co.; a-c.; 55,555 kv-a.; 90 per cent power factor; 13,800 volts; 3-phase; 60 cycle; 1800 r.p.m.

Exciter: General Electric Co.; d-c.; direct connected; 250 kw.; 250 volts; 1800 r.p.m.

Instruments

The steam pressure before the throttle was measured at two points by standard test gages, graduated to 1 lb. per sq. in. scale divisions. The temperature of the steam to the turbine was also measured at two points by engraved mercury thermometers, calibrated for total immersion. These thermometers were used in wells filled with solder with temperatures of the stem taken to correct for stem exposure.

The exhaust pressure was measured at the turbine exhaust nozzle by four absolute pressure type gages.

Condenser leakage was determined by an Evershed conductivity meter and miniature condenser. Steam from a main unit steam line was sampled under a vacuum to prevent contamination from gases in the atmosphere. The conductivity of the hotwell condensate was compared to the conductivity of the condensed steam, plus a small percentage of raw water. The amount of leakage was calculated.

The condensate from the main condenser was weighed on two Strait tank scales, equipped with a registering beam. Weighing was timed with a stop-watch.

Electrical data were taken from indicating laboratory instruments connected to each of the three phases. The wattmeters were read at minute intervals. Current transformers and all instruments used were calibrated before the tests. After the tests were completed, all instrument transformer ratios and phase angle corrections were checked.

Method of Conducting Tests

Tests were made at loads ranging from 20,000 to 54,000 kw. The tests were grouped into three series, with the back pressure on each series maintained constant at approximately 1, 1½ and 2 in. of mercury. The back pressure was controlled by admitting air at the suction of the vacuum pump.

The unit was operated with steam bled to the deaerating and closed feed water heaters, but evaporators were out of service during the tests. Condensate was pumped by the hotwell pump through the generator air cooler, oil cooler, No. 1 heater and then to main condensate weigh tanks. The water from the weigh tanks discharged into a test tank. It was then pumped through the heater vent condenser to the deaerating heater, discharging by gravity to the boiler feed pump. The feed pump discharge passes through No. 3 and No. 4 heaters to the boilers to complete the cycle. The flow diagram of the main condensate, the bleed steam and bleed condensate are shown in Fig. 25.

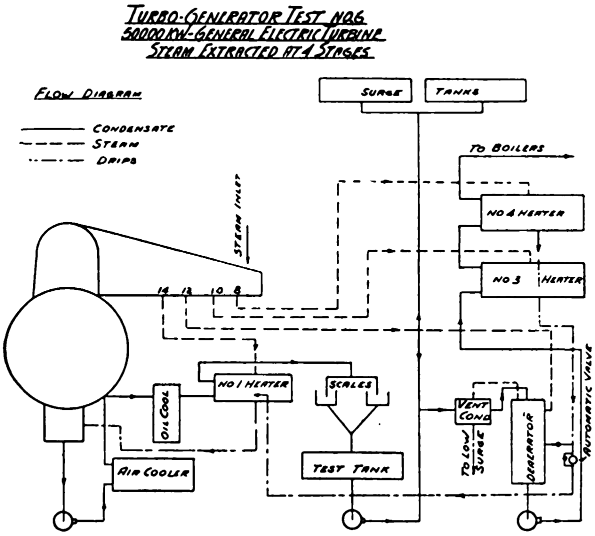

FIG. 25—FLOW DIAGRAM OF THE MAIN CONDENSATE, STEAM EXTRACTED AT FOUR STAGES OF THE TURBINE—TURBO-GENERATOR TEST NO. 6.

At light loads, the bleed condensate from the high pressure heaters normally goes to the No. 1 heater through an automatic unloading valve. When the pressure at No. 3 heater is sufficient to drain the bleed condensate into the deaerator, the unloading valve closes, discharging the drain into the water space of the deaerator. On runs No. 7, 8 and 9 the unloading valve was by-passed, the drain passing through No. 1 heater to the main condenser hotwell. Runs No. 14 to 28 inclusive were made with the valve in the drain line to the deaerator closed.

The turbine seals and the expansion joint were supplied with water taken from the condensate line between the condenser and the weigh tanks. The internal leakage from these seals drained to the condenser. The external leakage was separately weighed for each run.

The water for the condensate pump seals was taken from a surge tank. The amount was determined by the rate of the tank level change during the test.

Drainage from the vent condenser was weighed.

Computations

All calculations are based on the kilowatt output as obtained by the indicating wattmeters, corrected for instrument error. The integrated watthour meter output served to check the indicated output.

The heat consumption of the unit was calculated as follows:

Heat in steam at throttle, times the throttle flow; minus the heat of the liquid at final feed water temperature, times the flow through the final heater; plus the heat of the liquid at saturation temperature, at turbine back pressure, times net condensate; plus or minus heat in surge tank water due to level change; all divided by the load in kw.

In calculating the amount of steam extracted, the available heat of each pound of extraction steam was taken as the heat content of the steam entering the heater minus the heat of the liquid of the drain at the heater saturation temperature. When the drains were returned from a high pressure to a low pressure heater, the amount of heat added was taken as the difference in the heats of the liquids.

The quality of the bleed steam at the lowest extraction stage, when not superheated, was very near the saturation line on the Mollier diagram. The steam was assumed to be dry saturated when not in a superheated state.

The turbine is designed to operate with initial steam conditions at 315 lb. per sq. in. gage pressure and 725 deg. fahr. total temperature. Corrections provided by the manufacturer were used to reduce the water rates and the heat consumption of the unit actually obtained, to guarantee conditions.

Results

The test consisted of 28 runs. A detailed summary of the results of six of these runs, made at 29.0 in. of mercury vacuum, is shown in Table XXIV. In Table XXV similar data are presented for tests made at 28.5 and at 28.0 in. of mercury. Due to the change in level in the surge tanks between the start and the finish of the run there were variations between the throttle flow and the flow through the vent condenser, deaerator and the high pressure heaters.

Fig. 26, 27 and 28 show the water rate, heat consumption and thermal efficiency of the unit at constant back pressure corrected to guaranteed throttle steam pressure and temperature.

The total quantity of steam extracted from the turbine during the tests at 29.0 in. of mercury and the per cent of throttle flow that it represents at different unit loads are shown in Fig. 29.

The relation between the condensate temperature leaving the extration heaters and the loads on the unit is shown in Fig. 30.

TURBO-GENERATOR TEST NO. 7

Tests were made to determine the economy of the turbo-generator unit, when operating without extracting steam from the turbine, also when steam is extracted from three stages of the turbine to heat the feed water and to operate the evaporator. The range and variation of the extraction steam pressures between the turbine casing and the heaters were also investigated. Tests were made during March, 1927.

Test Apparatus Data

Turbine: General Electric Co.; 50,000 kw.; single cylinder; operating at 1200 r.p.m. It is designed for three stage steam extraction with initial steam conditions at 390 lb. per sq. in. gage pressure and 700 deg. fahr. total temperature.

Generator: General Electric Co.; 75,000 kv-a., 1200 r.p.m. alternator.

The first extraction nozzle, located at the fourteenth stage of the turbine, supplies steam to the first extraction stage feed water heater and the evaporator. The steam extracted at the second and third extraction nozzles, which are located respectively at the seventeenth and nineteenth stages of the turbine, is used only for feed water heating. The leakage from the high pressure shaft seals enters the second extraction stage heater.

The evaporator supplied with steam from the first extraction nozzle is so installed that the vapor can be directed either to an evaporator vapor condenser, located in the feed water heating system between the first and second extraction stage feed water heaters, or the vapor can be directed to the lowest pressure extraction heater which, during normal operation, is supplied only by steam extracted from the nineteenth stage of the turbine.

Method of Conducting Test

Extraction and non-extraction tests were made at generator loads ranging from 25,000 to 50,000 kw. with the turbine back pressure maintained constant at 1.0 in. of mercury.

Tests made with steam extracted from the turbine include observations for the specified range of loads with the evaporator vapor condensed in the evaporator condenser. To observe the effects of evaporator operation on the unit economy, tests were made at a constant load of 45,700 kw. with the evaporator out of service, also with the evaporator in service with the vapor condensed in the evaporator condenser on one test and the vapor condensed in the lowest pressure extraction heater on another test.

The feed water from the unit includes the steam condensed in the main condenser, the high pressure shaft packing steam leakage condensed in the second extraction stage heater, the bleed condensate from the evaporator and all extraction heaters and the condensate make-up added to the system by the evaporator. This feed water is pumped by the main condensate pump, respectively, through the third extraction stage heater, the second extraction stage heater, the evaporator condenser and the first extraction stage heater to the boiler feed pump to be returned to the boilers.

The extraction steam pressures were indicated by mercury filled manometers and steam temperatures were indicated by glass, engraved stem, thermometers in oil filled wells.

To obtain the pressure of the steam in the extraction chamber of the first extraction stage, the casing was drilled for a connection at a point 30 deg. below the horizontal center line of the casing. The inner opening of this pressure connection is in the chamber at the periphery of the fourteenth stage wheel. For the extraction chamber pressure connections at the third extraction stage the casing was drilled 45 deg. below the horizontal center line and a pressure connecting tube was brought out through the side of the exhaust casing.

The extraction steam temperatures were measured at a point near the pressure connection at the heater steam inlet, about 12 in. from the heater shell.

The steam supplied to the unit and the feed water passing through the feed water heaters during the tests were determined by flow meter measurements. Both the steam flow meter and the condensate flow meter were calibrated by weighed water tests.

The high pressure shaft packing leakage was measured by a pitot tube and a differential indicating manometer.

Results

A summary of the results of the tests with steam extracted from three stages of the turbine is shown in Table XXVI. Test run No. 19 was made with the primary valve full open, the secondary valve being throttled.

Test run No. 20 was made with the primary valve full open with the secondary valve closed. During test runs No. 21 and 22 the primary valve was throttled and the secondary valve closed. On test runs No. 19 to 22 inclusive, the evaporator vapor was condensed in the evaporator condenser.

Test run No. 25 was made with the primary valve full open with the evaporator vapor condensed in the third stage extraction heater instead of the evaporator condenser. Test run No. 26 was made at the same generator load as obtained on test run No. 19, but the evaporator was taken out of service and steam extracted, only, for feed water heating.

A summary of the test results when the turbine was operated without steam extraction is shown in Table XXVII.

Test run No. 15 was made with the secondary valve full open, test run No. 16 with the primary valve full open and test runs No. 17 and No. 18 with the primary valve throttled.

A heat balance diagram for the unit is shown in Fig. 31. The auxiliary power consumption is not deducted from the generator output when unit economy is considered.

The relation between the heat supplied to the turbine and the total heat extracted at the three extraction stages is shown in Fig. 32. The per cent of total heat to the unit that was extracted is also shown. In Fig. 33 the heat extracted at each extraction nozzle is graphically presented.

Method of Conducting Test

All tests made were of two hours' duration and ranged in load from 15,000 to 50,000 kw. During these tests the bleed steam valves and condenser make-up valves were closed. Condensate from the hotwell was supplied to the turbine seals.

The steam leak-off from the high pressure gland was condensed in the low pressure extraction heater and weighed.

The main unit condensate was weighed in test tanks. The drains from the atmospheric relief valve, the turbine seals and main condensate pump seals were separately weighed.

Steam pressure before the throttle was measured on calibrated test gages graduated to 0.5 lb. per sq. in. The throttle steam temperature was measured by special engraved test thermometers, graduated to 0.5 deg. fahr. The temperature indicated was corrected for stem exposure.

The vacuum at the turbine exhaust was measured on barometric type mercury columns.

The generator output was measured by the three wattmeter method. Calibrated split type current transformers were installed between the generator switch and the selector switches. The station potential transformers were used and calibrated for the burden carried during the tests.

A summary of the results of this test is presented in Table XXVIII with the water rate graphically presented in Fig. 37.

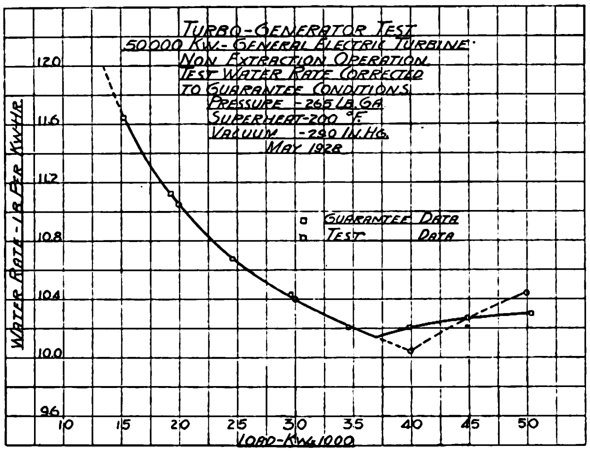

FIG. 37—WATER RATE CORRECTED TO GUARANTEE CONDITIONS, NO STEAM EXTRACTED FROM THE TURBINE—TURBO-GENERATOR TEST NO. 8.

TURBO-GENERATOR TEST NO. 9

This test was made to determine the economy of a General Electric turbo-generator unit when operating straight condensing, also when steam is extracted from three stages of the turbine to heat feed water. Test was made during August, 1927.

The turbo-generator unit, operating at 1800 r.p.m., is rated at 30,000 kw. The turbine is provided with three extraction nozzles located at the seventh, eleventh and fourteenth stages of the turbine. It is designed to operate with throttle steam at 375 lb. per sq. in. gage pressure and 258 deg. fahr. superheat with the exhaust pressure at 1.5 in. of mercury abs.

Steam consumption for the non-bleed tests was determined by a venturi tube and manometer installation in the main condensate line. This was corrected for leakage in the main condenser, condensate entering the condenser from the turbine shaft seals and the air ejectors. On the bleed tests the steam consumption was obtained by totaling the main condensate which was metered and the bleed steam to the individual heaters which was calculated from observed data. A venturi tube metering installation in the boiler feed line leaving the unit and a flow meter measuring the steam to the throttle were used to check the test results reported.

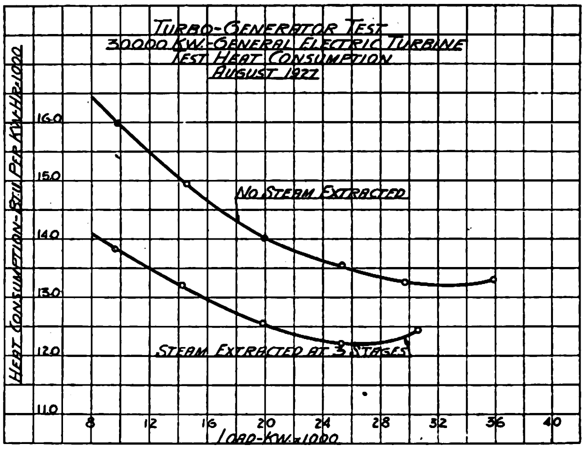

FIG. 38—HEAT CONSUMPTION, WITH AND WITHOUT STEAM EXTRACTED AT THREE STAGES OF THE TURBINE—TURBO-GENERATOR TEST NO. 9.

A condensed summary of the results of the tests made with steam extracted at three stages is shown in Table XXIX. Heat consumption for both test conditions is shown in Fig. 38.

Fig. 39 shows the path of the bleed steam and main condensate, also the heaters and coolers entering into the heat cycle of the unit.

TURBO-GENERATOR TEST NO. 10

The object of tests made during July, 1928, was to determine the water rate of the turbo-generator when operated without bleeding at loads at which guarantees were made by the manufacturer.

Test Apparatus Data

Turbine: Allis-Chalmers; 30,000 kw.; single cylinder; straight reaction; 1800 r.p.m.; exhausting into a single pass, 30,000 sq. ft. surface condenser.

Generator: Allis-Chalmers; a-c.; 30,000 kw.; 80 per cent power factor; 12,000 volt; 3-phase; 60 cycle; 1800 r.p.m.; served by a 100 kw. direct connected exciter which is excited by a small pilot exciter of a 4 kw. capacity.

Instruments

Special test gages were used to measure the steam pressure at the throttle. Normal operating gages were used

for steam pressure measurements after the primary and secondary valves.

All temperatures were taken from mercury in glass thermometers. A 6-in. immersion laboratory thermometer was used to measure the steam temperature at the throttle. The stem of this thermometer was immersed in solder to the immersion mark and no stem corrections were applied to the temperature as indicated by this instrument. The exhaust steam temperature was read from industrial type thermometers.

Two mercury columns located at opposite corners of the turbine exhaust opening, measured the vacuum on the turbine.

Calibrated measuring tanks were used to determine the quantity of condensate discharged from the condenser. The electrolytic conductivity method of determining condenser leakage was used, but no trace of raw water contamination was detected, and condenser leakage was considered to be zero on all tests.

The electrical output was measured at the generator terminals by integrating watthour meters and a duplicate set of indicating wattmeters. The output by the integrating meters was used for checking purposes only. Instrument transformers used were calibrated previous to the test, with the same secondary burden which they were to carry during the tests.

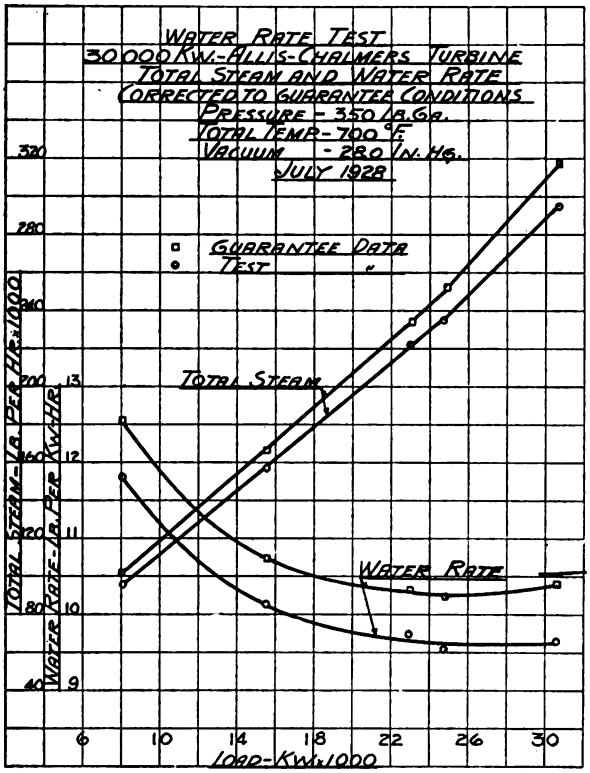

FIG. 40—TOTAL STEAM AND WATER RATE, NO STEAM EXTRACTED FROM THE TURBINE—TURBO-GENERATOR TEST No. 10.

Method of Conducting Tests

The tests were made at one-quarter, one-half, three-quarter, most efficient and full loads. Observations on each test covered a period of two hours.

The turbine is provided with four extraction nozzles. The two low pressure nozzles supply steam for feed water heating, the next higher pressure nozzle supplies steam for evaporator operation and the highest pressure nozzle supplies steam for cracking scale from the evaporator coils. During these tests, all bleed lines were closed and no steam was extracted from the turbine. To keep the bleed lines free from condensate, the drains from the two low pressure bleed lines were trapped to the condenser. Valves in these drain lines were cracked slightly during the tests.

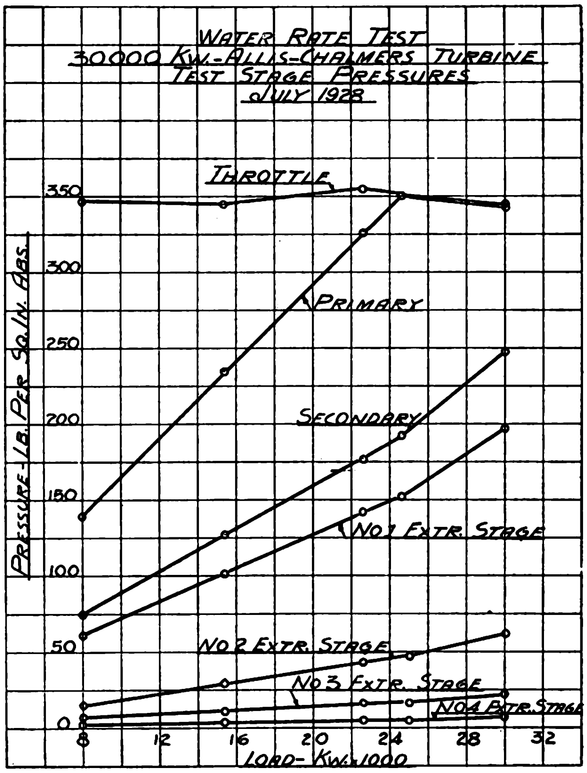

FIG. 41—STAGE STEAM PRESSURES, NO STEAM EXTRACTED FROM THE TURBINE—TURBO-GENERATOR TEST No. 10.

The hotwell condensate was pumped through the ejector condenser to the calibrated measuring tanks.

The primary jet of the air ejector drains back to the hotwell of the main condenser. The amount of steam supplied to the primary jets was calculated from the nozzle dimensions and deducted from the condensate withdrawn from the condenser.

A booster pump withdraws condensate from the discharge side of the condenser condensate pump and discharges to the seal tank from which water flows by gravity to seal the turbine shaft and the atmospheric relief valves. The overflow from the seal tank, the leakage from the turbine seals and the overflow from the atmospheric seals were drained to a measuring tank and the condensate, withdrawn for sealing use, which was not returned to the condenser was accounted for on every test.

Results

A summary of the test data is shown in Table XXX. Fig. 40 shows the total steam Willans' Line and the steam consumption per kilowatt-hour for test results corrected to guarantee conditions. It also shows the performance guaranteed by the manufacturer for non-bleeding operation.

The curves in Fig. 41 show the relation between the load on the unit and the stage steam pressures.

Fig. 42 shows the thermal efficiency of the unit for non-bleeding operation and the Rankine Cycle efficiency ratio of the unit based on actual steam conditions and output measured at the generator terminals.

TURBO-GENERATOR TEST No. 11

The object of tests made during October, 1928, was to determine the heat consumption of the turbo-generator unit

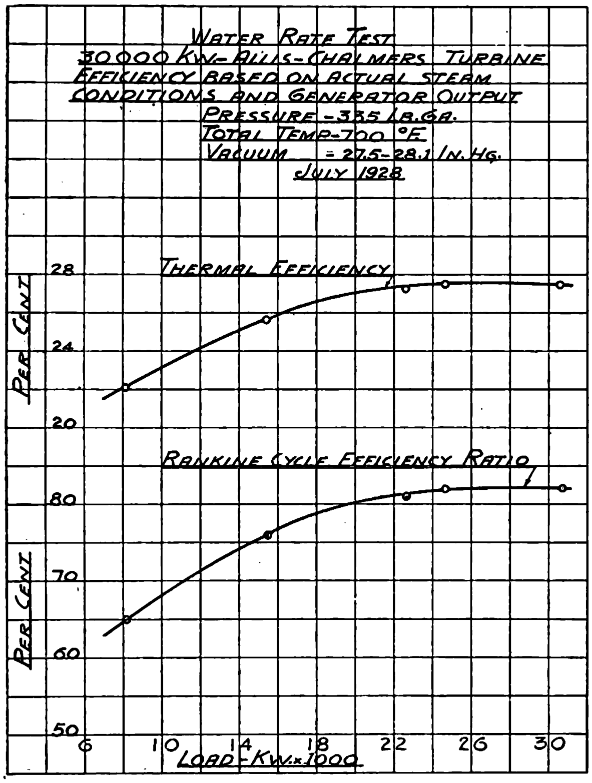

FIG. 42—THERMAL EFFICIENCY AND EFFICIENCY RATIO, NO STEAM EXTRACTED FROM THE TURBINE—TURBO-GENERATOR TEST NO. 10.

when steam was extracted from three stages of the turbine for feed water heating.

Test Apparatus Data

Turbine: Allis-Chalmers; designed to operate with steam at 400 lb. per sq. in. gage pressure, 725 deg. fahr. total temperature and 2 in. of mercury back pressure. It is of the full reaction type designed to extract steam from three stages to heat the condensate from the unit as it is returned to the boiler feed system.

Generator: Allis-Chalmers; 3-phase, 50 cycle, 11,000-volt alternator, rated at 15,000 kw. at 80 per cent power factor and 1500 r.p.m. The excitation is furnished by a 100 kw.. 250-volt direct connected exciter.

The low pressure and the high pressure extraction heaters are of the closed-heater type furnished by the Griscom-Russell Co. The intermediate extraction heater is of the open-heater type built by the Cochrane Co.

Method of Conducting Test

The condensate from the main condenser was pumped by the main condensate pump to the weigh tanks. This included the main turbine condensate, water from condenser tube leakage, the drains from the steam jet air pump and the low pressure heater bleed condensate. The sealing water for the turbine glands and the atmospheric relief valve was so circulated in the system that they did not influence the results of the condensate weighed at the tanks.

The condenser tube leakage was determined by weighing the leakage that took place with normal water circulated through the condenser, with the condenser steam space under atmospheric pressure. The amount thus obtained was corrected to test condition by increasing the tube leakage in proportion to the increase in pressure difference between the steam and water space of the condenser for the two conditions.

The steam pressure at the turbine throttle was maintained constant at the pressure specified in the guarantee by manual steam pressure control. Because the boilers superheat the steam higher than guarantee, the steam temperature at the throttle could also be maintained practically constant by the use of a de-superheating jet placed in the main steam line and supplied with water from the boiler feed system. With exception of the test made at approximately 4000 kw. when the steam demand was low, little difficulty was experienced in maintaining the desired steam pressures and temperatures.

When the load on the unit was such that the intermediate bleed stage was under a vacuum, steam was supplied to the intermediate, open type, extraction heater from the high pressure bleed stage.

Tests were made at approximately one-quarter, one-half, three-quarter and full loads with the duration of each test from two to three hours. The unit was operated with steam extracted from the three stages of the turbine and operation was normal except that the evaporator which normally receives steam from the intermediate extraction stage and discharges the vapor to the open heater was out of service.

Computations

The quantity of bleed steam to each extraction heater was calculated from the heat absorbed by the feed water passing through the heater and the heat in the bleed steam transferred to the feed water. The total heat of the bleed steam to the low pressure heaters was obtained from information furnished by the manufacturer.

No corrections were necessary for the temperature and pressure of steam supplied to the turbine. The vacuum correction applied was based on the ratio of the actual available heat in the steam to the available heat under guarantee conditions. This correction was applied to the steam exhausted to the condenser.

The steam consumption of the air ejector reported at 900 lb. per hr. was based on factory tests. As the drains from the ejector discharge into the main condenser this amount was deducted from the weighed condensate in calculating the turbine steam consumption.

The condenser leakage with the turbine out of service amounted to 125 lb. per hr. under vacuum. This was calculated to reach 250 lb. per hr., the correction being applied to the condensate as weighed.

Results

A summary of the data and results of this test are presented in Table XXXI.

In Fig. 43 the heat consumption of the unit is shown for test results corrected to guarantee conditions and also the guaranteed performance when operating on the regenerative cycle.

TURBO-GENERATOR TEST NO. 12

This series of tests was made during August, 1928, to determine the water rate of the turbo-generator unit when operated straight condensing.

Test Apparatus Data

Turbo-generator: Allis-Chalmers; rated at 6000 kw. at 80 per cent power factor; 2300/4000 volts; 3-phase; 60 cycle; operating at 36,000 r.p.m. The turbine exhausts into an Allis-Chalmers two pass; 11,750 sq. ft. surface condenser.

Turbine: Designed to operate with initial steam at 235 lb. per sq. in. gage pressure and 520 deg. fahr. total temperature and exhausts to the condenser at 2.0 in. of mercury, back pressure. The unit is operated straight condensing although the turbine is provided with four extraction nozzles.

Results

Steam consumption of the unit was obtained by weighing the condensate from the main unit condenser and subtracting from this the weight of the primary ejector drains and the turbine seal water that appeared as condensate from the condenser, but did not represent steam supplied to the unit. Tests for condenser leakage disclosed that no leakage was present during the water rate tests.

Results of these tests are summarized in Table XXXII.

The high back pressure on run No. 2, made at 3024 kw. load on the unit was due to abnormal condenser conditions that did not prevail during the other runs of the test series.

Run No. 3 was made as nearly as possible at the most efficient load, which is just below the load at which the overload valve opens.

The actual steam rate corrected to guarantee conditions and the guarantee steam rate over the entire load range are shown in Fig. 44.

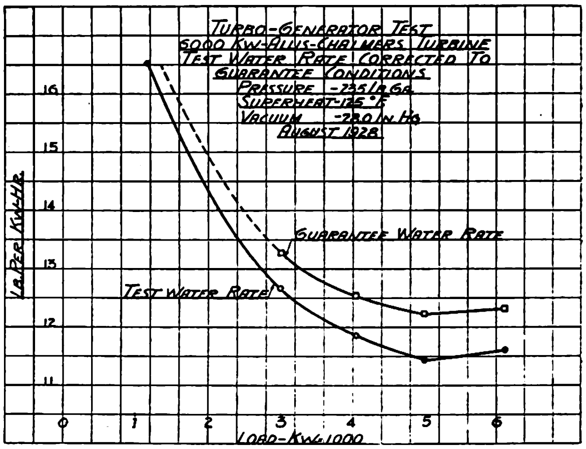

FIG. 44—ACTUAL AND GUARANTEED WATER RATE, NO STEAM EXTRACTED FROM THE TURBINE—TURBO-GENERATOR TEST NO. 12.

OPERATING COMPANIES' STATEMENTS

STATEMENT BY THE ALABAMA POWER CO., BIRMINGHAM, ALA.

During the annual inspection of the 30,000-kw. General Electric turbine, in January, 1928, one-half of the retaining shoulder, holding the fourth stage nozzle diaphragm against axial movement was found to be cracked as shown in Fig. 45 and 46. The turbine is a 17-stage Curtis, 1800 r.p.m. machine operating with steam conditions at 200 lb. per sq. in. gage pressure, 200 deg. fahr. superheat and 1.0 in. of mercury back pressure. For load up to 22,000 kw. steam is admitted only to the first stage nozzles. For loads above 22,000 kw. and up to 30,000 kw. additional steam is admitted to the fifth stage, before the diaphragm nozzles, through a secondary inlet valve. This secondary steam enters the turbine at an annular ring (cast integral with the shell), through a radial opening. It was at this opening that the break occurred.

The part of the casing adjoining the crack that separated from the shoulder formed a strip 51 in. long. The middle section of this strip separated from its original position

approximately ⅝ in., but the ends remained intact. No material damage was done to the rotating parts. Nothing was observed on which an estimate of the cause or the date of the break could be based. That it occurred some time between February, 1927, and January, 1928, is all that is known.

The damaged piece was removed by cutting at each end. To hold the fourth stage diaphragm in its proper place, a keyway was cut both in the shell and the lower half of the diaphragm at the bottom diameter of each. This is illustrated in Fig. 47. The key inserted at this point was designed to take all of the stress imposed by the diaphragm. A very small clearance was left between the diaphragm and the original shoulder while the machine was cold. With the machine at operating temperature the diaphragm is believed to be in its normal position against the remaining shoulder, imposing little, if any, stress on it.

The machine has not been inspected since repairs were made. No further break at this shoulder is anticipated even though the cause of the original break has never been determined.

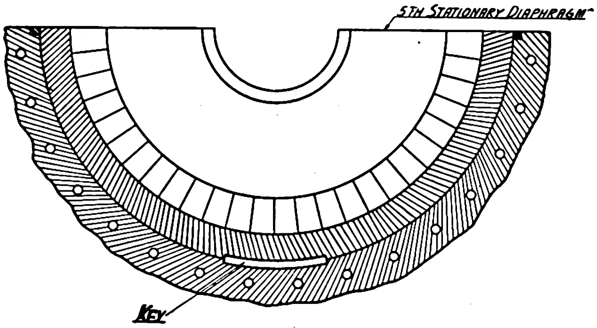

FIG. 47—LOCATION OF KEY HOLDING THE DIAPHRAGM IN PLACE, 30,000-KW. GENERAL ELECTRIC TURBINE—ALABAMA POWER CO.

STATEMENT BY W. S. BARSTOW & CO., READING, PA.

Holland Station

The turbo-generator unit for the Holland Station consists of a high pressure and a low pressure turbine rated at a total capacity of 55,750 kw. The specified steam conditions are 1250 lb. per sq. in. gage pressure and 750 deg. fahr. total temperature at the throttle of the high pressure turbine with the low pressure turbine exhausting into a condenser at 29.0 in. of mercury. Data pertaining to the unit are presented in Table XXXIII.

TABLE XXXIII

TURBINE DATA—HOLLAND STATION, NEW JERSEY POWER & LIGHT COMPANY.

1. Capacity of unit, kw.	55,750
2. Capacity of high pressure element, kw.	11,920
3. Capacity of low pressure element, kw.	43,830
4. Speed of high pressure element, r.p.m.	3,600
5. Speed of low pressure element, r.p.m.	1,800
6. Voltage, volts	13,800

The steam at the high pressure exhaust varies in pressure from 100 lb. per sq. in. gage at 13,000 kw. load to 416 lb. per sq. in. gage at 55,750 kw. The high pressure exhaust passes through the steam and gas reheater increasing the temperature to 750 deg. fahr. before being admitted to the low pressure turbine.

The turbine is designed for multivalve steam admission to give a low steam consumption over a wide range of load.

Steam is bled from the high pressure exhaust and the sixth, tenth and fourteenth stages of the low pressure turbine to heat feed water. The final feed water temperature is 433 deg. fahr. at rated turbine load.

An exciter direct connected to the low pressure unit excites both the low pressure and the high pressure generator. A sub-exciter on the same shaft dispenses with the field rheostats on the generator.

The low pressure turbine is provided with an emergency governor that operates the trip valve. It also has a control governor that can be used if the low pressure turbine is operating alone. Under normal conditions, the high pressure governor will control all operation with the high pressure exhaust passing through the reheater to the low pressure turbine.

STATEMENT BY THE COMMONWEALTH EDISON CO., CHICAGO, ILL.

Automatic Frequency Control

The perfection of frequency control in an electricity supply system is very desirable in order that operating companies may render the best possible service. While variations in frequency are not always as readily apparent as variations in voltage, they are objectionable in all classes of service where uniform speed is a factor.

The advantages of automatic frequency control lie not alone in precision speed regulation, but also in improved parallel operation of power stations and interconnected power systems. Economies resulting from such control are rather intangible but can best be measured by the effect on system interconnections, the decrease of so-called power drifts from one system to another and in the promotion of merchandise sales.

Factors Entering into Control Design

Frequency is ideally controlled when a predetermined standard is continuously maintained. To attain this standard it is necessary that the energy supply for the turbines vary simultaneously with every variation in system load. This is automatically approached by the use of electrical and mechanical relays that cause the energy supply to change almost simultaneously with demand on the system.

Load changes on the system cause the corrective stimulus to be applied. Since the inertia of the entire rotating system of turbines, converting apparatus, and motor load is involved, over-regulation is likely to take place unless the corrective measure is limited and stability readily established. This dictates that the automatic control should be intermittent with corrective influence applied steadily until the desired correction is complete.

The natural period of oscillation of long interconnecting lines between electric systems is in the order of the time it takes the usual turbine governor to respond to changes in loading. For these reasons it seems most desirable that the corrective influence of the automatic control should be small, intermittent and applied at periods entirely out of the range of natural periods of oscillation of any part of the system under control.

The control should be such that its operation will not lower the efficiency of the plant nor produce undesirable load swings on the station apparatus. Neither should it affect the system nor the unit under its direct control due to failure of any of its parts. It should relinquish control during periods of manual frequency regulation of the unit on which it is installed and in case of a system disturbance of any moment the effects of the control must be instantly removed.

With these and other limitations in mind a controller was built and installed on a 90,000 kw. unit. Due to the governor characteristic and the setting of the admission valves at this unit undesirable load swings would occur. The control was therefore transferred to a 75,000 kw. unit where its performance was very satisfactory.

Description of Control and Its Operation

The frequency control includes two major divisions, the one maintains close instantaneous frequency and the other prevents the integration of a time error as measured by an

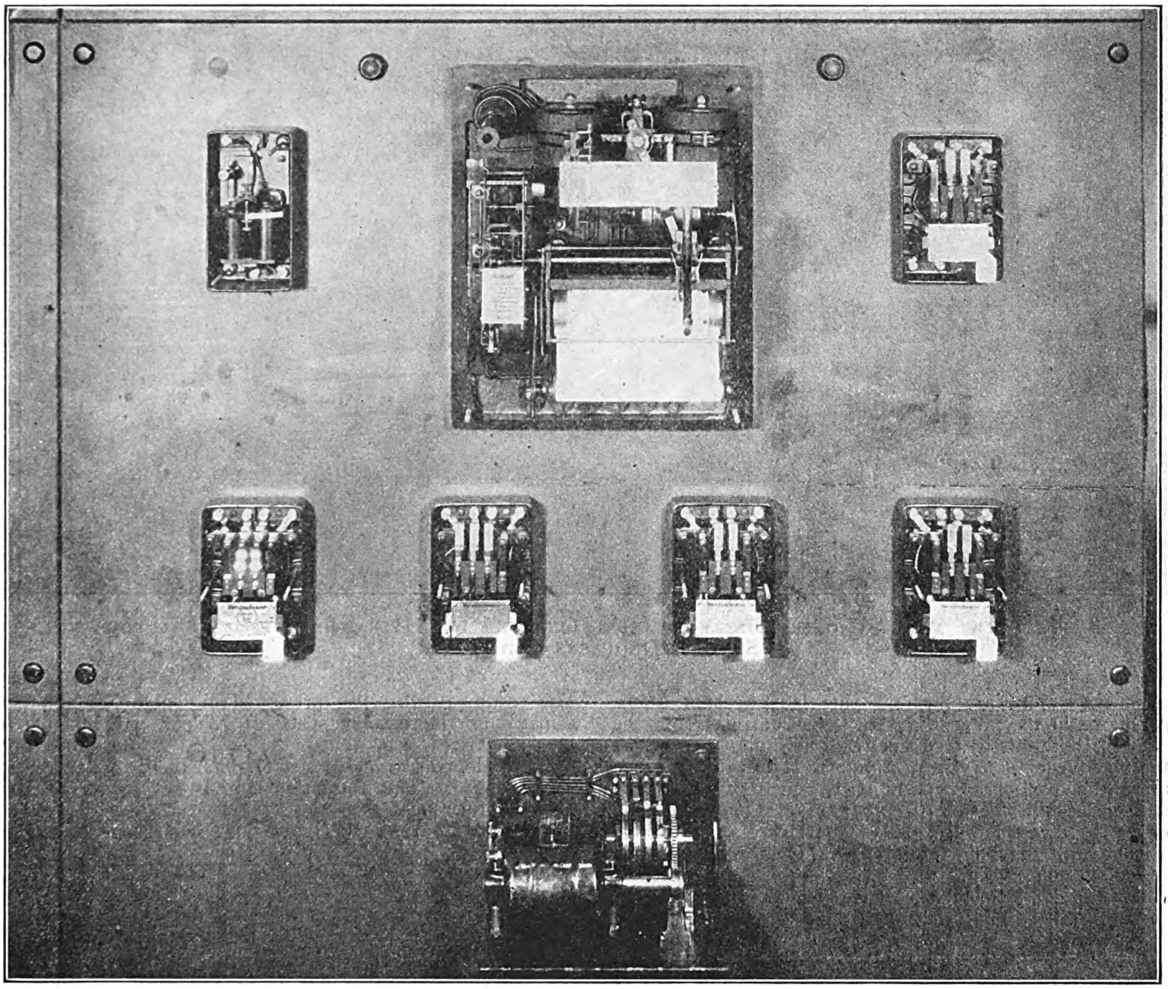

FIG. 48—SWITCHBOARD FREQUENCY CONTROL APPARATUS—COMMONWEALTH EDISON CO.

electric clock. The switchboard apparatus is shown in Fig. 48. No additional equipment at the turbine was necessary as the control operates the standard governor motor.

The first part of the controller consists of a contact-making device operated by a high grade frequency meter. Its function is to maintain an instantaneous frequency within 0.05 cycle plus or minus, and operates from 0.05 to 0.25 cycle plus or minus of the adopted standard. The control automatically goes out of service when deviations in frequency exceed 0.25 cycle.

While the frequency meter used is the best obtainable it is difficult to maintain an accuracy of more than 99.95 per cent. Even with such a degree of accuracy it is true that time-frequency integration may be in error.

The second part of the controller operates within 0.05 plus or minus of the standard frequency and takes care of possible inaccuracy of the frequency meter. It consists of a set of synchronous motor driven contactors, relays and a high grade precision clock, the accuracy of which is frequently checked against U. S. observatory time signals.

The synchronous motor operated cam-contactors acting between contacts on the clock mechanism and the governor control motor on the turbine, serve to synchronize the frequency-time with clock-time. The device goes through this operation once each minute, offering the corrective impulse to the turbine. If the timing of the electric system is correct, no corrective impulse is transmitted. The duration of this impulse is about one second and the load change on the unit is approximately 1000 kw.

In order that the load on a unit will not be seriously disturbed by a protracted tendency for the system frequency to run high or low, a load-range relay was devised to limit the possible load change to within any desired range which is selective at the option of the operator. If the unit is to operate at an average load of 60,000 kw. the load limit device is set to cover the range from 50,000 to 70,000 kw. If the control should cause the load to change more than 10,000 kw. plus or minus, the device goes out of service and attracts the attention of the operator.

Inaccuracies in frequency meters and master clocks were at once revealed by the operation of the control. It was found possible, however, to hold the frequency within 0.05 cycle plus or minus and can now be maintained at will for indefinite periods. The system frequency obtained with manual and automatic regulation is shown in Fig. 49.

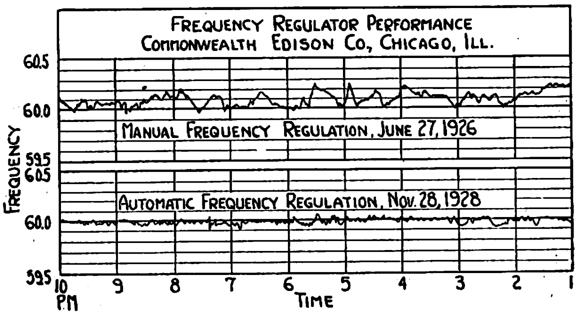

FIG. 49—FREQUENCY WITH AND WITHOUT AUTOMATIC REGULATION—COMMONWEALTH EDISON CO.

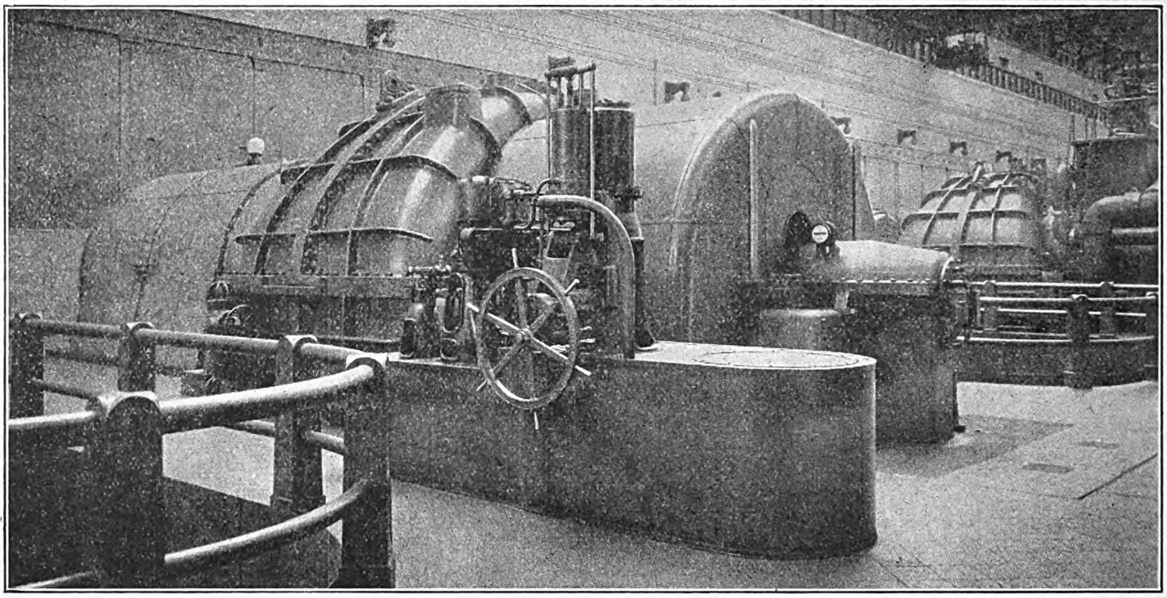

FIG. 50—41,250-KW. WESTINGHOUSE, SINGLE-CYLINDER TURBINE WITH HYDRAULIC TYPE OF GOVERNOR—COLFAX STATION, DUQUESNE LIGHT CO.

Present indications are that the sluggish governor seems to have more in its favor than the sensitive one from the standpoint of automatic frequency regulation.

Actual load variations from minute to minute on a large system as the one in connection with which this company operates are small. The load swings on the controlling station are in the order of 7000 to 10,000 kw. on a system which has a load of about 900,000 kw. and is interconnected with other systems.

By means of this control the entire system in the Chicago area, including the Public Service Co. of Northern Illinois, The Commonwealth Edison Co., the Northern Indiana Public Service Co., the Illinois Superpower Co. and also the Ohio-Michigan Power Co. have been able to operate so as to maintain correct frequency-time for periods of twenty-four hours and more. This means that the greatest error at any time during this period was less than one second and also that the greatest error in frequency was 0.05 cycle.

Experience gained over a period of six months indicated that it is desirable to control more than one unit in the Chicago district in order not to disturb tie line loads and station operation. Two controllers are now in service and at least three more will be in the near future. The machines so controlled will be in two or possibly four stations.

STATEMENT BY THE DUQUESNE LIGHT CO., PITTSBURGH, PA.

Hydraulic Governors

During the year 1927 two Westinghouse, 41,250 kw. turbo-generating units were installed at the Colfax Station of this company. These units, one of which is shown in Fig. 50, are of the single cylinder, Bauman type, arranged for four stage bleeding.

These turbines are equipped with hydraulic type of governors. The governors consist essentially of an impeller, mounted directly on the turbine shaft, producing an oil pressure proportional to the square of the turbine speed. This pressure actuates a relay controlling the steam supplied to the turbine. The impeller also serving as a pump supplies oil to the governing mechanism, the lubrication system and to an ejector that maintains a positive pressure in the impeller suction chamber to insure stable operation.

Tests were made on one of these turbines to investigate the performance of the hydraulic governor and determine the increase in speed, when full load is suddenly released. The results of this test presented in Table XXXIV show a maximum increase in speed of 7.7 per cent when a load of 43,500 kw. was released. Fig. 51 shows the turbine speed, and primary valve travel immediately after the load was dropped. The automatic stop is set to operate at 11 per cent overspeed.

The operation of the governors has been satisfactory.

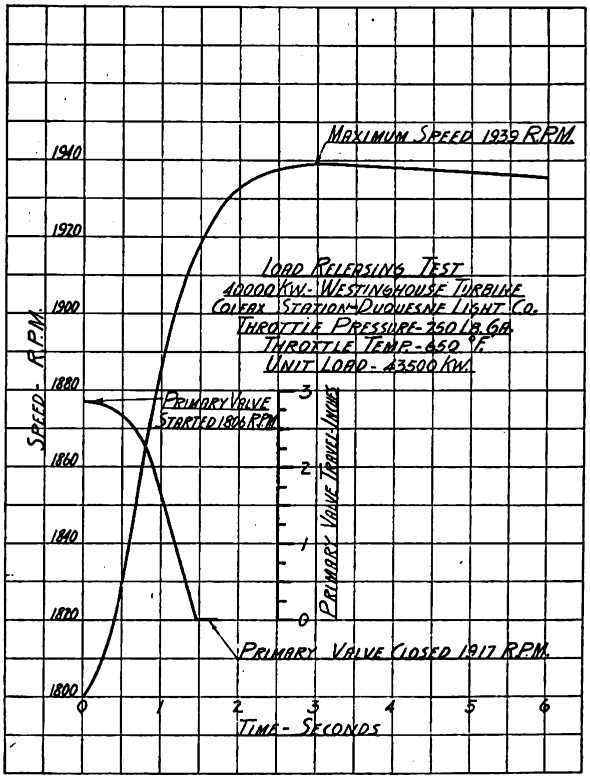

FIG. 51—TURBINE SPEED RISE AND PRIMARY VALVE TRAVEL AFTER FULL LOAD WAS RELEASED ON HYDRAULICALLY GOVERNED TURBINE—COLFAX STATION, DUQUESNE LIGHT CO.

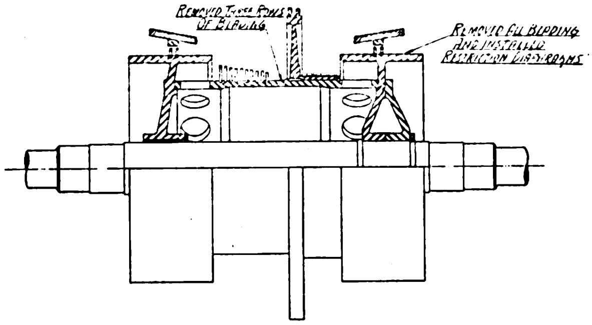
Emergency Auxiliary Power Supply

No. 3 unit at the Brunot Island Station of this company, as originally installed, consisted of a 3000 kw., 12,000 volt generator, driven by a Westinghouse combined impulse-reaction turbine, exhausting into a jet condenser.

During the year 1925 the unit was converted into a house unit to serve as an emergency source of power for the electrically driven station auxiliaries. The generator was rewound for 2300 volts, and the turbine blading changed, as shown in Fig. 52.



Removed Three Rows of Blading
Removed All Blading and Installed Restriction Diaphragms

FIG. 52—SPINDLE FOR 3000-KW. WESTINGHOUSE TURBINE CONVERTED INTO EMERGENCY HOUSE UNIT—BRUNOT ISLAND STATION, DUQUESNE LIGHT CO.

Water rate tests were made on the unit after the blading change, with and without the jet condenser in service. These tests show that the improvement in economy when operating condensing was not sufficient to warrant the use of the condenser. The condenser was removed, and the turbine exhaust connected to the auxiliary exhaust header to aid in maintaining the station heat balance.

When in service the unit either operates as an auxiliary generator, if exhaust steam is required, or it operates as a synchronous condenser. When operating as a synchronous condenser, a decrease in the auxiliary bus frequency will decrease the speed of the unit. The governor will respond, admitting steam to the turbine to maintain its speed, generating power for auxiliary use. When the load on the generator reaches 1600 kw., the 2300 volt bus is automatically separated from the 11,000 volt bus to prevent feed back. The auxiliaries are then supplied by this unit.

The power consumption of the unit when operating as a condenser is 300 kw.

When first placed in service, there was some doubt as to whether the turbine would heat up excessively when operating as a synchronous condenser, due to turbine windage. Readings taken at various points on the turbine casing showed a maximum temperature of 335 deg. fahr.

Due to the high steam consumption, the unit is operated only during abnormal station conditions, storms or when the station load reaches a value where the loss of the electrically driven auxiliaries would interrupt service.

STATEMENT BY THE KANSAS CITY POWER & LIGHT CO., KANSAS CITY, MO.

High Pressure Installation at North East Station

The 1200 lb. per sq. in. pressure turbo-generator installed at the North East Station is rated at 12,500 kv-a., 1800 r.p.m.

The complete installation will consist of one 12,500 kv-a., Westinghouse turbo-generator, two 16,950 sq. ft. Ladd boilers equipped with Elesco connection superheaters and shielded type radiant reheaters.

The turbine is of the Westinghouse parallel flow type, made up of a two velocity stage impulse element and about twenty rows of reaction blading. The turbine is designed to operate with throttle steam conditions at 1200 lb. per sq. in. gage pressure and 725 deg. fahr. total temperature. The pressure at the turbine exhaust is about 315 lb. per sq. in. gage. This unit, under complete control of the governor, can be contrasted with the high pressure units first operated when load was controlled by the boiler pressure.

Under the above steam conditions the unit will have a water rate varying from 45 lb. per kw-hr. to 34 lb. per kw-hr. at loads from 5000 to 10,000 kw., respectively. The exhaust steam from this unit will be reheated by a furnace type reheater to about 675 deg. fahr. for use in the main turbine operating at normal station pressure.

The design of this turbine is unique in many respects, departing radically from the standard type of unit. Particular attention has been given to the design, so the alignment of the unit will not be effected by expansion or by stresses applied by connecting high or low pressure piping.

The entire installation was designed and installed by engineers of the Kansas City Power & Light Co.

New Installation at Grand Avenue Station

This company recently acquired the 25 cycle generating plant of the Kansas City Street Railway Co., which contained boilers and generating equipment operated with steam at 185 lb. per sq. in. gage pressure and about 80 deg. fahr. superheat. Because the Street Railway Co. did not see fit to replace their substations with 60 cycle equipment that could be supplied with power from the present 60 cycle generating station, it became necessary to remodel the 25 cycle equipment. The fact that the 25 cycle system in all probability would not increase in size, and the further fact that this old station would be developed to contain ultimately around 150,000 kw. of modern 60 cycle generating equipment, did not warrant any extensive changes in the 25 cycle end of the plant.

In order to obtain a uniform high pressure boiler plant which would at the same time supply the low pressure 25 cycle units and the new 60 cycle units, it was decided to install at this time three 1500 h.p., 700 lb. per sq. in. gage pressure boilers and one 10,000 kw., 600 lb. per sq. in. gage non-condensing steam turbo-generator. This turbine will exhaust at 190 lb. per sq. in. gage and sufficient superheat to operate the required part of the present turbines and also to supply the necessary steam for a new connection to the present downtown heating system. All future 60 cycle units to be installed in this station will consist of 600 lb. per sq. in. gage condensing type units probably operating on a reheat cycle.

The turbine recently installed is a General Electric 12,000 kv-a. unit operating at 590 lb. per sq. in. gage and 740 deg. fahr. total temperature and exhausting into the present station header system at 190 lb. per sq. in. gage and approximately 100 deg. fahr. superheat. This turbine will have a water rate varying from 44 lb. per kw-hr. to 38 lb. per kw-hr. at loads from 5000 kw. to 10,000 kw., respectively.

Steam for operating this turbine will be supplied by three 15,000 sq. ft. Ladd boilers of a modified three drum Stirling design. Each boiler unit is designed for a normal evaporation of 150,000 lb. per hr. and a maximum evaporation of 225,000 lb. per hr.

The design of this station is being made by the Kansas City Power & Light Co., and the engineering and construction are being done by the United Light & Power Engineering and Construction Co.

STATEMENT BY THE MILWAUKEE ELECTRIC RAILWAY & LIGHT CO., MILWAUKEE, WIS.

Test of 7700 kw., 1200 lb. per sq. in. turbine

The second high pressure turbine at the Lakeside Station was placed in operation during January, 1929. This unit is rated at 7700 kw., which is 700 kw. higher than the first machine installed, because it operates with higher steam pressure and superheat. In all major respects it is identical with the first unit. Tests of the 7000 kw. unit are reported in the 1927 serial report on Higher Steam Pressures and Temperatures.

The unit was operated in compound with a 300 lb. per sq. in. pressure condensing turbine, both isolated from the remainder of the station. The condensate from the low pressure machines was weighed and corrected for condenser leakage, etc. Two three-hour tests were made on separate days. The unit was loaded at full capacity on all tests.

Possibility of high pressure extraction heater leakage was eliminated by using heaters on another recently installed condensing machine to heat feed water to the high pressure boiler. Other test details were similar to those reported for the tests of the 7000-kw. unit.

Test results in Table XXXV, show a water rate of 32.7 lb. per kw-hr. for the unit, with steam conditions at 1230 lb. per sq. in. gage, 750 deg. fahr. at throttle and 317 lb. per sq. in. gage at the exhaust. This corresponds to an efficiency ratio of 77.7 per cent computed on the electrical output basis. The efficiency ratio of the first machine was 75.5 per cent. The gain is principally the result of improved interstage leakage, though the blading is in better condition and low pressure seal leakage is slightly less.

The 77.7 per cent efficiency ratio compares favorably with that of large low pressure machines, showing that higher pressure stations are not handicapped by lowered turbine efficiencies.

STATEMENT BY THE PUBLIC SERVICE CO. OF COLORADO, DENVER, COLO.

This company, operating interconnected steam and hydro units, installed on the steam turbine an electric contact actuated by the throttle valve tripping mechanism so that it will trip the generator oil circuit breaker at the same time that the main throttle valve closes due to overspeed. This was done to prevent the hydro machine, when it loses its load, from motoring the steam-driven unit to a speed exceeding the desirable, 10 per cent, maximum for steam units.

Where hydro and steam plants operate on a system with long transmission lines, it is possible under some conditions for the hydro plant and the steam plant to be tied together at a time when the entire load is lost. The hydro machine, unable to reduce its speed at as fast a rate as the steam machine, will rise to a higher speed than is permitted for the steam unit.

STATEMENT BY THE UNION ELECTRIC LIGHT & POWER CO., ST. LOUIS, MO.

Frequency Regulator

A Leeds-Northrup frequency regulator was tried at Cahokia Station on the several main generators with the purpose of automatically controlling the system sixty cycle frequency over a narrower range than is possible with hand regulation. After correcting some minor deficiencies in the regulating instrument this has been accomplished. With hand regulation a range of 0.4 cycle (0.2 cycle too fast to 0.2 cycle too slow) is customary. Automatic regulation reduces this range to 0.1 cycle with a range of 0.05 being possible. The frequency record for both manual and automatic regulation is shown in Fig. 53.

This has been achieved, however, at the expense of a greatly increased fluctuation of load on the turbo-generator under regulation. Ordinarily the system regulation is cared for by regulation on one machine. Two machines have been placed under control of the regulator at one time, but even turbines of identical design do not parallel sufficiently well to maintain balanced loading. One or the other of the two units tends to take the greater portion of the load after a short period. With one 35,000 kw. unit controlling the frequency on the 60-cycle system, steam flow to the turbine has fluctuated from 240,000 to 340,000 lb. per hr., as often as eight times an hour. Single surges have changed the steam flow from 160,000 to 350,000 lb. per hr. and back to

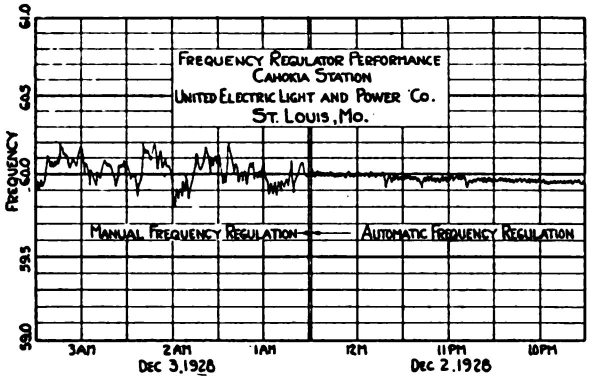

FIG. 53—FREQUENCY REGULATOR PERFORMANCE—CAHOKIA STATION, UNITED ELECTRIC LIGHT & POWER CO.

150,000 lb. per hr. in fifteen minutes. The steam flow record for one of the turbines when the frequency is controlled by manual and automatic regulation is shown in Fig. 54 and 55.

This wide variation is partly due to the fact that one unit is attempting to control the frequency for an electrical system which includes another steam plant. One 35,000-kw. unit is thus regulating a 60-cycle load of 210,000 kw. As governor characteristics differ on the various machines with two stations the problem cannot be readily solved by installing several regulators because of the tendency of one machine to take the entire load.

The wide fluctuation in turbine loading is not in line with desirable operation. It would cause undue strains on the blading because such a variation represents a wide range in load and in steam temperature, especially in the lower stages.

In addition to the effect on the turbine, the heat balance and auxiliaries are affected, especially units bleeding from more than one stage. Such a condition is encountered in connection with a 50,000-kw. unit, of which four stages are bled to heat feed water. Several of the adjustments on this heat balance system must be made by hand. These include adjustments to the boiler feed pump loads and the throttling of bleed line valves. As an example, steam extracted from the 12th stage is supplied to a deaerating

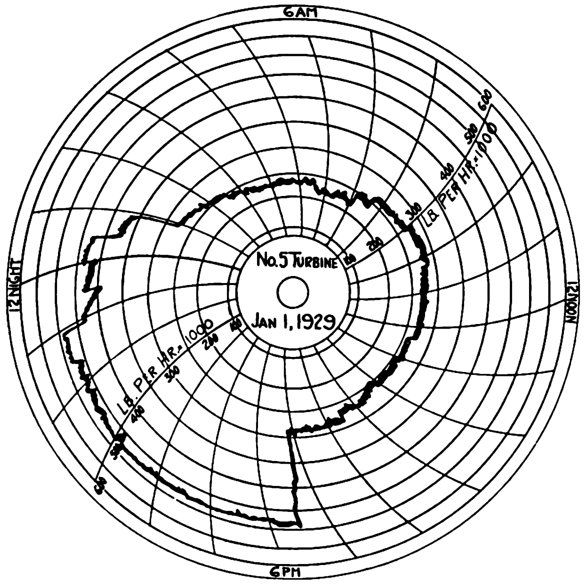

FIG. 54—STEAM FLOW TO TURBINE WITH MANUAL FREQUENCY REGULATION—CAHOKIA STATION, UNITED ELECTRIC LIGHT & POWER CO.

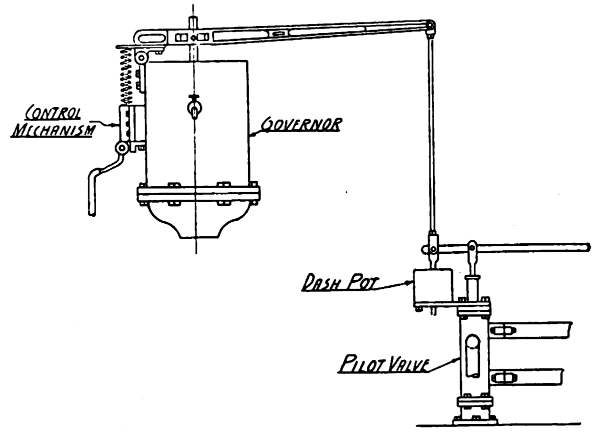

FIG. 57—DASH POT AS INSTALLED ON GOVERNOR LINKAGE—WEST END STATION, UNION GAS & ELECTRIC CO.

heater (steam to water contact). If the pressure is too high in this heater, water will not enter from the surge tank, and the boiler feed pump drains the heater, the pump becomes steam bound and the operation is interrupted. Consequently, the pressure of bleed steam to the heater must be controlled by hand throttling. With automatic frequency regulation the fluctuation in load and stage pressure is too rapid to permit reliable hand control of valves.

It may be concluded that in its present form the frequency regulator is not adaptable to Cahokia load conditions. The violent swings in load on individual units, and the inability of two units to parallel in regulation, cause fluctuation in turbine loads that would cause severe strains. On units with elaborate stage bleeding systems, the auxiliary operation is adversely affected.

STATEMENT BY THE UNION GAS & ELECTRIC CO., CINCINNATI, OHIO

Governor Dash-Pots

When the electrical tie connections between the three stations of the Columbia System were completed and put into operation it was found that system disturbances would in many cases start oscillations in the power output of the various generators. Under certain conditions, these oscillations would not dampen out, but would continue at a steady rate until checked by manual operation, which usually took the form of retarding the motion of the pilot valves on the governors.

It was observed on tests that a dash-pot installed in the governor linkage system would dampen the oscillations set up by system disturbances and would bring the turbines back to steady operation. The details of the dash-pots installed on the governors of the turbines at the West End Station are shown in Fig. 56 and the installation is shown in Fig. 57.

Since the installation of the dash-pots all the governors have been overhauled by the manufacturer in order to be certain that the regulation is correct. The governors of base load units have a regulation of 7 per cent at full load, while the governors on other units are set at 5 per cent. These governor settings have proven very satisfactory.

Changes Made in the Vertical Struts in Exhaust Casings

The exhaust casing of each turbine installed at the Columbia Power Station is designed with a vertical strut in the top and in the bottom half as shown in Fig. 58. The one face of the web strut was 11 in. from the leaving edge of the blades in the last stage and was 5 in. wide. It was believed that the blades were subjected to additional stresses as they pass the web faces, and that vibration could be set up which might result in blade failures.

In order to improve this condition, portions of the webs were cut away as shown in Fig. 58 and the clearance between the blade and the web faces increased to 20 in.

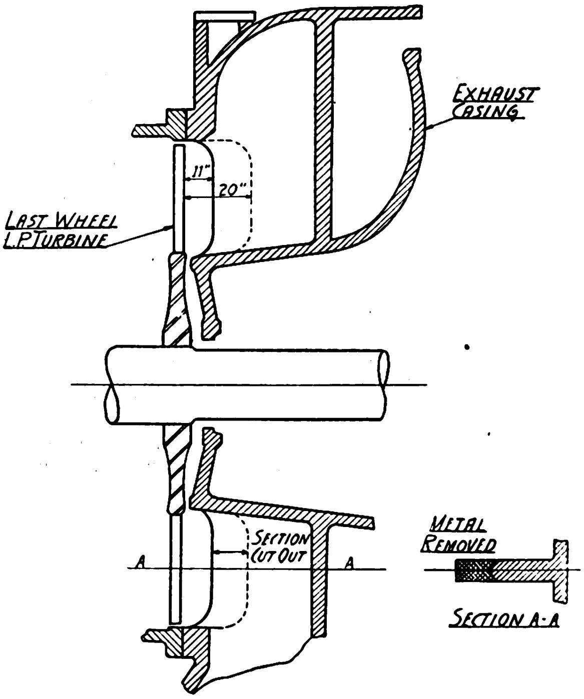

FIG. 58—SECTION OF VERTICAL STRUTS REMOVED FROM EXHAUST CASING—COLUMBIA STATION, UNION GAS & ELECTRIC CO.

MANUFACTURERS' STATEMENTS ON LARGE TURBINES

The Prime Movers Committee Does Not Accept Responsibility for Any Manufacturers' Statement

STATEMENT BY THE ALLIS-CHALMERS MANUFACTURING CO., MILWAUKEE, WIS.

To improve the steam turbine apparatus, this company observes the operation of its large turbines in the field studying the performance of the detail parts and the expansion movements of the machines under conditions encountered in service. This work is carried on with machines which are satisfactory in every respect and free from trouble. This is combined with a careful study of the operating and repair records of the machines, with the result that many of the essential details such as labyrinth packing, water seal, shaft glands, etc., were improved. The improvements, while of a minor nature, have contributed greatly to make the turbines reliable in operation, making them largely immune to difficulty in case of reasonably quick starting. This company found that making an engineering study of successful operating machines has enabled it to obtain a better insight into the operating problems.

Work is continued, perfecting the details of manufacturing processes on all parts of the turbine. Appreciable headway has been made in this company's plan of perfecting

the manufacture of the turbine shaft, so that it will be in approximate balance when completely assembled, and before any balancing is done.

The 50,000-kw., 1800-r.p.m. tandem compound turbo-generator unit installed in the Waukegan Station of the Public Service Co. of Northern Illinois, has now operated for approximately two years and has proven entirely satisfactory. This unit operates with 600 lb. per sq. in. gage steam pressure, 725 deg. fahr. total temperature and 29 in. of mercury vacuum. No troubles or delays were encountered in erection or subsequent starting of the unit. No balancing of either the turbine or generator rotors was necessary. The machine has operated without detectable vibration during its starting periods.

At the end of the first year of service the unit was opened for annual inspection. The interior of the turbine was found in good condition, and very little work was necessary other than the cleaning processes usual after a year's operation. Up to the time of this inspection the cylinder covers have not been lifted since the unit was assembled during erection.

The unit was started 48 times during its first year of operation. The longest time taken to bring it up to speed was 59 minutes, the shortest time 26 minutes. The average starting time for 44 starting periods was 48 minutes. For a period of approximately a month the unit was taken out of service daily.

Results of the test of the 50,000-kw. unit at Waukegan Station are shown in Table XXXVI. The economy was found better than guaranteed.

During the past year, two 30,000-kw. units were placed in operation. The first, for the Consumers Power Co., Jackson, Mich., operated with a steam pressure of 350 lb. per sq. in. gage at the turbine throttle, superheated to a total temperature of 700 deg. fahr. with 29 in. of mercury vacuum at the exhaust. The second unit, for the Oklahoma Gas & Electric Co., Harrah, Okla., operates with a steam pressure of 275 lb. per sq. in. gage at the turbine throttle, superheated to a total temperature of 700 deg. fahr. with 28.5 in. of mercury at the exhaust. Both of the above units are single flow with uni-directional double flow exhaust blading. The results of the test on the 30,000-kw. unit for the Consumers Power Co. also showed an economy better than guaranteed.

Three 15,000-kw. units were installed since the 1927 report. The first, for the Florida Public Service Co., Avon Park, Fla., operates with 400 lb. per sq. in. gage steam pressure at turbine throttle superheated to a total temperature of 715 deg. fahr. with 28.5 in. of mercury vacuum at the exhaust. The second, installed for the city of Pasadena, Cal., operates with the same steam pressure, but with a total steam temperature of 725 deg. fahr. and 28.0 in. of mercury vacuum at the exhaust. The third, for the Madison Gas & Electric Co., is to operate with a steam pressure of 205 lb. per sq. in. gage at the turbine throttle, 100 deg. fahr. superheat and 28.5 in. of mercury vacuum at the exhaust. The third unit is designed for future operation with 250 lb. per sq. in. gage steam pressure and a total steam temperature of 650 deg. fahr. The design of these units is shown in Fig. 59. The first two units have been operating successfully for some time. The erection of the third unit is completed and will be placed in service in the near future.

This company has under construction a 20,000-kw. unit for Riverside Power Manufacturing Co., Davenport, Iowa. This unit will operate with 400 lb. per sq. in. gage steam pressure with a steam heat content of 1362 B.t.u. per lb., vacuum at turbine exhaust nozzle 28.5-29.0 in. of mercury. This unit is scheduled to be in operation in the early fall of this year.

STATEMENT BY THE AMERICAN BROWN BOVERI ELECTRIC CORP., CAMDEN, N. J.

The 160,000-kw. cross-compound turbo-generator unit installed at the Hell Gate Station of the United Electric Light & Power Co., was placed in operation during the latter part of 1928.

This company has a turbine under construction, designed

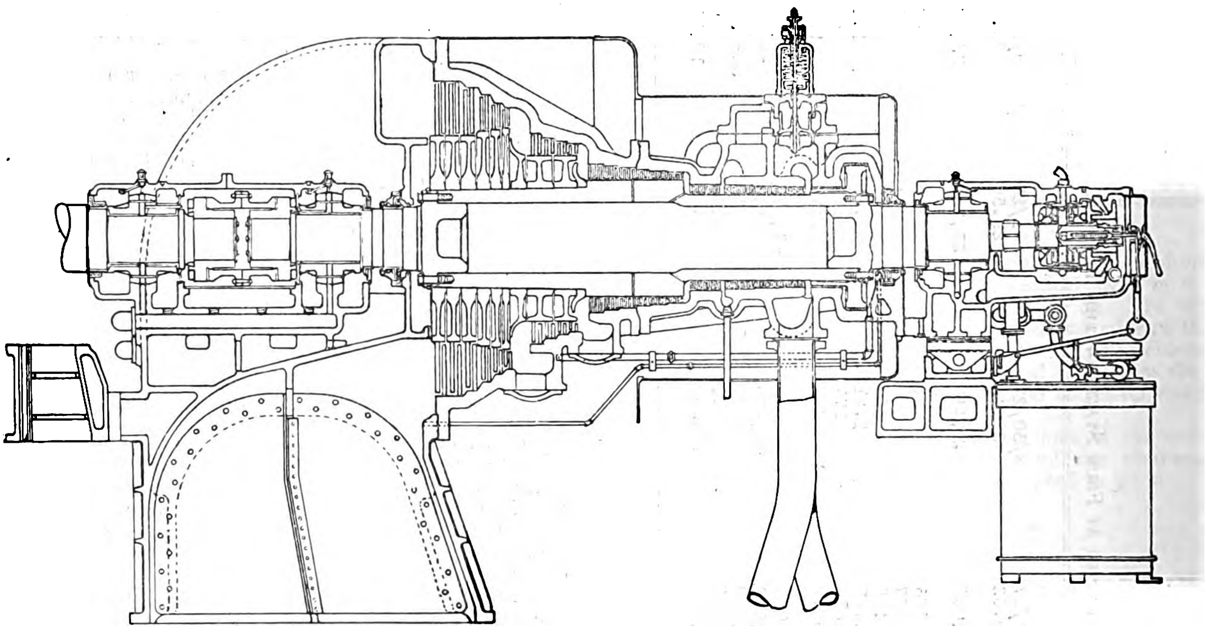

FIG. 59—CROSS-SECTION OF 15,000-KW., 1800-R.P.M. TURBINE—ALLIS-CHALMERS MFG. CO.

to operate with throttle steam conditions of 1400 lb. per sq. in. gage pressure, and 700 deg. fahr. total temperature, exhausting at a back pressure of 360 lb. per sq. in. gage. This unit is rated at 3700 kw., at 3600 r.p.m.

STATEMENT BY THE GENERAL ELECTRIC CO., SCHENECTADY, N. Y.

Steam turbine development during the past two years followed two major trends, one toward units of larger capacity and the other toward the extensive use of 1200 lb. per sq. in. pressure.

The trend toward larger units is clearly indicated by Fig. 60, which shows the maximum rating of different types of steam turbines manufactured by this company. The relatively recent compound units increased in capacity to 208,000 kw. and the tandem compound units, with double flow exhaust having a single shaft and driving a single generator, increased in size to 160,000 kw. While Fig. 60 shows only the units of maximum rating, an analysis of all units on order show a progressive movement toward turbines of larger average unit capacity.

The trend toward higher pressure is indicated by the selection, after exhaustive calculations, of 1200 lb. per sq. in. as the most economical turbine pressure for the new stations at Deepwater, N. J., and at Holland, N. J. The generating equipment at the Deepwater Plant, the first station to be designed for 1200 lb., will consist of a 12,500-kw. high back pressure unit and two 53,000-kw. cross-compound condensing units. The unit for the Holland Station is of the cross-compound, condensing type rated at 55,000-kw. capacity. Turbines with a total capacity in excess of 300,000 kw. manufactured by this company have been shipped or are on order, and there is every indication that the use of 1200 lb. per sq. in. pressure will continue to increase.

The 208,000-kw., triple cross-compound turbine for the State Line Generating Co. has been shipped and will soon be in operation.

The 165,000-kw., triple compound set is in service in the Philo Station of the Ohio Power Co.

Fig. 61 shows the ventilating housing of the 160,000-kw., 1500-r.p.m., 11,400-volt generator for the large tandem compound turbine which has been shipped to the East River Station of the New York Edison Co. The turbine is of tandem compound construction with double flow in the low pressure end and is designed for 375 lb. per sq. in. gage and 700 deg. fahr.

Fig. 62 shows the stator frame of welded steel plate construction. The rocking trunnions facilitate tipping the frame

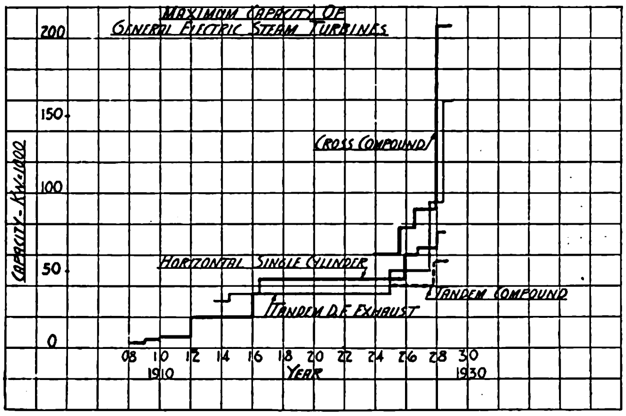

FIG. 60—MAXIMUM RATING OF GENERAL ELECTRIC STEAM TURBINES—GENERAL ELECTRIC CO.

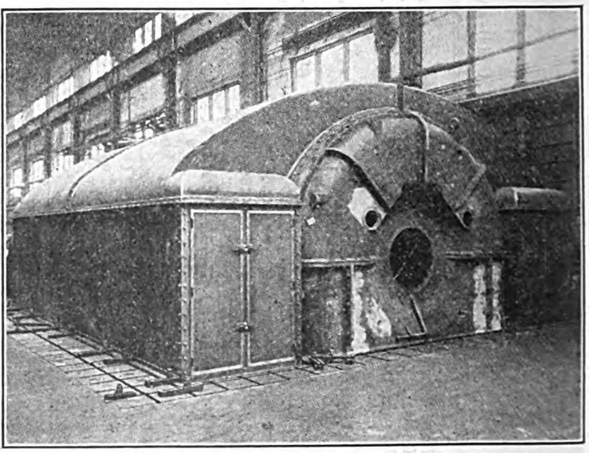

FIG. 61—VENTILATING HOUSING FOR 160,000-KW. GENERATOR—GENERAL ELECTRIC CO.

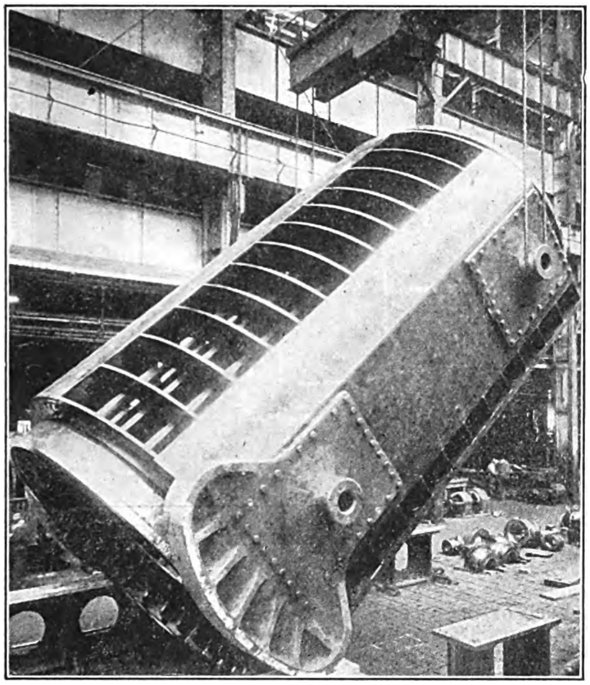

FIG. 62—WELDED STATOR FRAME FOR 160,000-KW. GENERATOR—GENERAL ELECTRIC CO.

on end. An unusual feature in the construction of this generator is the stator winding. It is composed of two separate windings which are identical in all respects, but are electrically independent so that the capacity of each is 80,000 kw. The two sets of windings are connected through two generator breakers to adjacent bus sections thereby affording the following advantages:

1. The possibility of obtaining half load from one of the windings without regard to the other half.
2. The reduction in generator circuit breaker capacity by the use of two generator circuit breakers.
3. The elimination of bus reactors made possible by the transfer of power taking place through the coupling effect of the two separate windings.
4. The increased stability obtained by omitting the bus reactors.

The 94,000-kw. unit of the Southern California Edison Co. is shown partially installed in Fig. 63. The operation of this unit has been very satisfactory since installation, and it has carried maximum load practically continuously except for 3 or 4 hours at night. The generator is the largest now operating and was the first to be wound for 16,500 volts. It is rated 90,000 kw., 100,000 kv-a., 50 cycle, 1500 r.p.m. The stator has a frame of welded steel plate construction and was assembled, wound and tested at the factory and shipped complete.

The largest 1800 r.p.m. single-cylinder turbine under construction is a 75,000-kw., 17 stage unit for the Cahokia Station at St. Louis. It is designed for steam pressure of 315 lb. and 725 deg. fahr. total temperature. The unit has four bleed points and will supply feed water heating for a total of 110,000-kw. capacity. It will occupy no more space than now occupied by a 35,000-kw. unit.

A 75,000-kw., 1500-r.p.m., single-cylinder turbine was recently installed in the Huntley Station of the Buffalo General Electric Co. The steam conditions are 250 lb. per sq. in. and 660 deg. fahr.

Fig. 64 shows the 65,000-kw., 1800-r.p.m. unit in the Edgar Station of the Edison Electric Illuminating Co., Boston, described in the statement by this company in the 1927 report. This unit was one of the first to be equipped with a service generator, which is shown clearly in the photograph.

A 55,000-kw. tandem-compound single-flow reheat turbine is operating in the Pekin Station of the Super Power Co. of Illinois and a duplicate unit is on order. The generators of these machines were the first to be wound for 22,000 volts.

Three more 50,000-kw., 1500-r.p.m. turbines have been shipped to the Detroit Edison Co., who now have six units

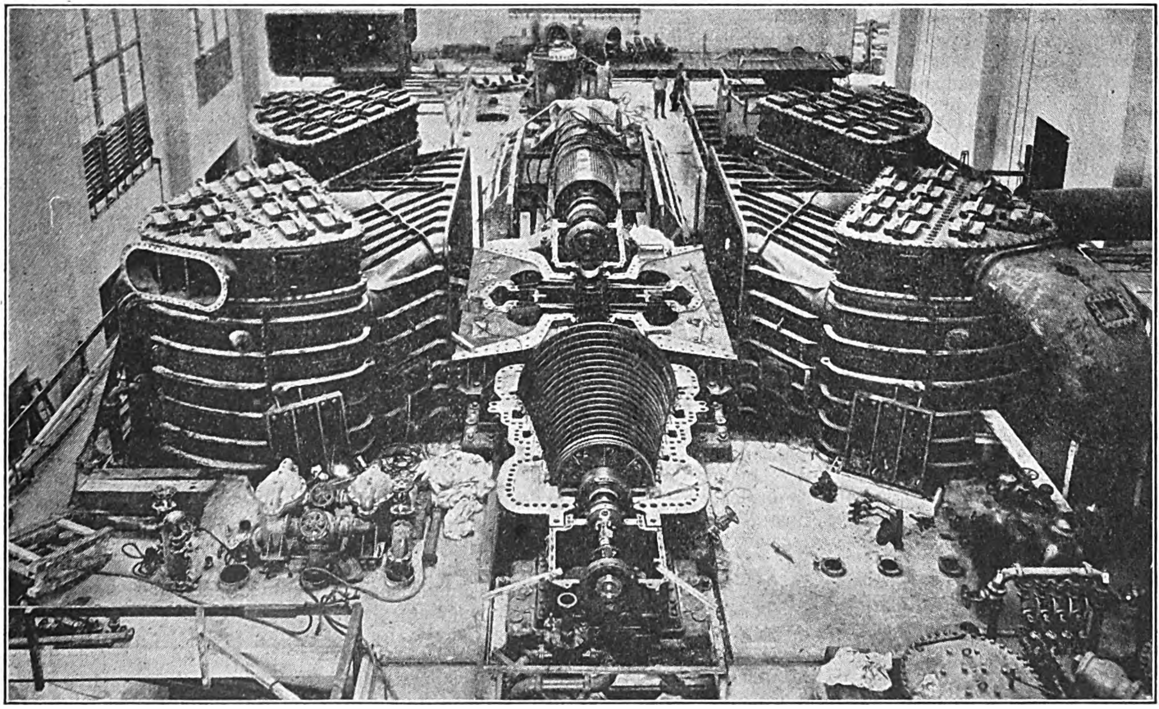

FIG. 63—94,000-KW. TURBO-GENERATOR PARTLY INSTALLED IN LONG BEACH STATION NO. 3 OF SOUTHERN CALIFORNIA EDISON CO.—GENERAL ELECTRIC CO.

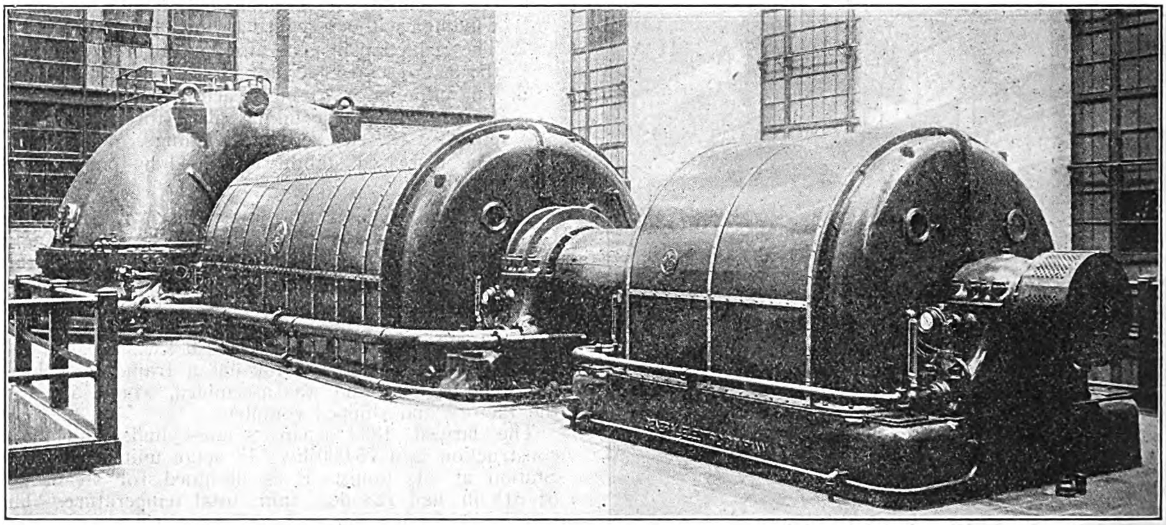

FIG. 64—65,000-kw., 1800-r.p.m. Turbine in Edgar Station of Edison Electric Illuminating Co.—General Electric Co.

of this type in their Trenton Channel Station and two in their Delray Station.

During the past two years the use of generator surface air coolers has increased to such an extent that practically all turbo-generators of 1000-kw. capacity and larger are now equipped with air coolers. This company has in operation surface air coolers serving more than 8,000,000 kw. of turbo-generator capacity.

The mercury vapor plant equipment installed in the South Meadow Station at Hartford, Conn., was put into commercial service during October, 1928, and operated in the most satisfactory manner. The first runs have indicated the desirability of certain modifications that will require a few weeks, meanwhile it should be appreciated that no fundamental changes are involved, but merely minor adjustments. The preliminary results indicate that the fuel economy of the process is better than predicted because of a high mercury turbine efficiency.

Research work is being carried on today as intensively as at any time in the past in order that this company may continue to meet the demands of the industry. This company has been able to design new units with every confidence that the expected efficiency and performance would be realized. That this expectation is well founded is proved by the results of complete turbo-generator tests that have been made during the past two years on a large number of representative turbines of different ratings that thoroughly cover the range in capacity. It is significant that machines tested, more than met their guarantees.

Statement by the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa.

Turbo-Generator Development

During the year 1928 eight large turbo-generator units, manufactured by this company, were placed in service. The capacities of these units range from 15,000 kw. to 110,000 kw., representing a total of 397,000 kw. During the same period eleven units of 15,000-kw. capacity or larger, totaling 414,000 kw., were sold. Two of these are already installed and are included in the number in service as reported above.

Among the units which were placed in service during the year the following are worthy of special note:

104,000-kw. unit in the Crawford Avenue Station of the Commonwealth Edison Co.
60,000-kw. unit in the Lakeside Station of the Milwaukee Electric Railway & Light Co.
110,000-kw. unit in the Hudson Avenue Station of the Brooklyn Edison Co.

Each of these large units passed the preliminary stage in operation. They were placed in commercial operation without troubles of any consequence and are showing excellent performance. The designs of these units were covered in this company's statement of the 1927 report.

A test, made by the Milwaukee Electric Railway & Light Co. on the 60,000-kw. unit showed results approximately 1½ per cent better than the guaranteed performance.

Three units were inspected in which it was found the blade rings had moved excessively in the cylinders. Steps were taken to avoid any recurrence. The supports were altered and dowels provided so as to allow only radial movement of the rings with respect to the rotor.

Vibration troubles have not presented any entirely new problems and, by continuing our investigations along the same lines as reported for preceding years, very gratifying results have been obtained. It is interesting to note that of the eleven large spindles which were placed in service during the year, only one required any considerable amount of field balancing.

There have been no developments to indicate the necessity or desirability of any decided change in our standard blading practice. Consequently, our position on this subject remains unchanged. The sources of supply of stainless steel material are now adequate and the manufacturing processes for working this material have been developed so that stainless steel blades can now be produced in any quantities desired.

In the 1927 report this company referred to the oil operated governors on the 40,000-kw. units at the Colfax Station of the Duquesne Light Co. as the first governors of this type to be applied to large, central station units. During the past year two additional units, namely, the 104,000-kw. unit at Crawford Avenue and the 65,000-kw. unit at Lakeside, were placed in operation and the oil-operated governors are performing as satisfactorily as those on the Colfax units. The governor on the unit at Lakeside is greatly simplified and the desirability of this oil-operated type for large central station units is now established beyond question.

A new turbine was developed that operates at 3600 r.p.m. and bears a nominal rating of 10,000 kw. This is a single-cylinder, single-flow, complete expansion unit of the combination impulse and reaction type.

Four openings are provided in the cylinder, at different pressure stages, for extracting steam to heat feed water.

The cylinder consists of a base and cover, bolted together in the horizontal plane of the centerline, each being made in two parts joined by a vertical flange. The high pressure section is made of cast steel while the low pressure section is of cast iron. The vertical joint is made up permanently during the erection and, thereafter, the base and cover each can be handled as a single piece.

The cylinder is supported and anchored to the foundation at the low pressure end by two feet, one on each side of the exhaust chamber. These feet are bolted to the cylinder proper and can be removed to facilitate handling during shipment and erection.

The thrust or high pressure end is supported on an I-beam section which is placed transversely so that the elasticity of the web allows free movement axially to take care of expansion and contraction of the cylinder parts.

The rotor consists of a solid nickel steel forging. The use of this material allows higher working stresses and consequently reduces the length of the rotor considerably. The turbine rotor is coupled directly to the generator rotor by means of a solid flanged coupling and only three main bearings are used for the complete turbo-generator unit.

A dummy or balance piston is provided to counterbalance the major part of the axial thrust which results from the pressure drop across the reaction blading. The remainder of the thrust is carried by a thrust bearing of the standard Kingsbury type. This thrust bearing includes a worm and wheel adjusting feature similar to that provided on the 1800 r.p.m. machines, by means of which the rotor can be moved axially to obtain correct setting without dismantling any turbine parts.

The steam chest is mounted on top of the cylinder cover and carries four valves which control the flow of steam to the nozzles. The valves are operated by a standard oil-operated governor of the same design as has been used on the 3600 r.p.m. turbines during the past five years. The throttle valve is of the oil-operated, quick-closing type. Other features, such as the main bearings, overspeed automatic trip, glands, etc., are of standard design according to past practice.

MANUFACTURERS' STATEMENTS ON SMALL TURBINES FOR AUXILIARY DRIVE

Statement by the Allis-Chalmers Manufacturing Co., Milwaukee, Wis.

The Allis-Chalmers 3600 r.p.m. steam turbine is designed primarily for service as a prime mover in smaller and isolated power stations. The design is similar in general detail to that used for large central station machines. This company has not developed what might be termed an "industrial type of turbine" for sizes larger than 750 kw.

Auxiliary steam turbines and generators for large steam power plants are supplied by this company from a standard type of 3600 r.p.m. turbines. In general, the capacity of these machines varies from 2500 kw. to 6000 kw. for use with steam pressures up to 350 lb. per sq. in. gage and 400 lb. per sq. in. gage; and in capacities from 6000 kw. to 10,000 kw. for steam pressures up to 500 lb. per sq. in. gage.

There are available machines at 3600 r.p.m. of the non-condensing and high back pressure type designed for high efficiencies. These have shown remarkably good operating efficiencies and great reliability.

Fig. 65 shows the similarity between 6000-kw., 3600-r.p.m unit and the large central station 20,000-kw., 1800-r.p.m. unit. The single-cylinder construction is used with small diameter at inlet where the pressure and temperature are high and with an ample exhaust casing in which is provided a rigid support for the bearing and coupling structure between the turbine and generator. Such machines have had excellent operating records with the minimum repairs, with the greatest blading reliability. The larger unit in Fig. 65 is rated at 20,000 kw., operating with steam at 400 lb. per sq. in. gage pressure.

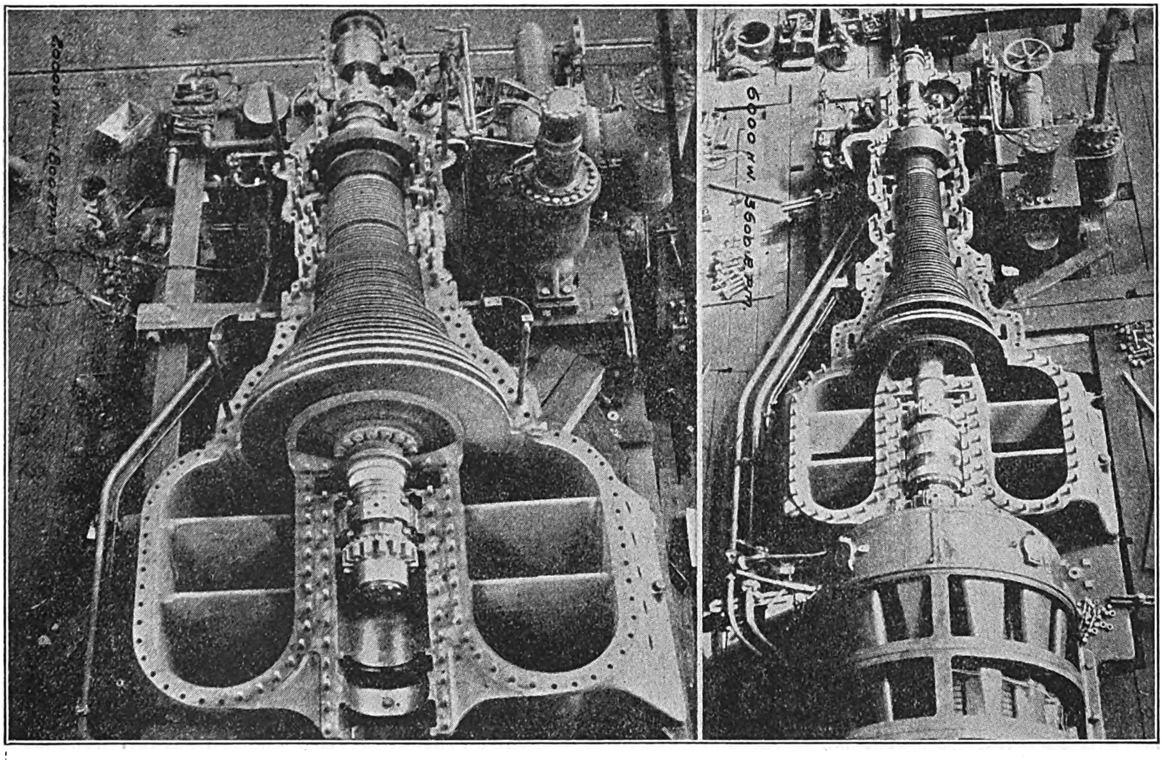

FIG. 65—6000-KW., 3600-R.P.M. AND 20,000-KW., 1800-R.P.M. TURBINES, SHOW SIMILAR CONSTRUCTION—ALLIS-CHALMERS MFG. CO.

STATEMENT BY THE DE LAVAL STEAM TURBINE CO., TRENTON, N. J.

This company is engaged in the development of turbines for auxiliary drives operating at high steam temperatures and pressures.

The principal departure from other types of turbines, for this class of service, is that the steam chest is placed in the cover of the turbine instead of in the lower half. This particular feature has proved very valuable in high pressure, high temperature steam plants as it eliminates the need for water cooling and permits the use of ring oiled bearings. This is a feature that cannot be satisfactorily accomplished when the steam chest is placed below the center line of the shaft.

This company has made particular efforts to locate all valve parts or other parts requiring adjustment above the center line of the turbine, where they are in open view of the operator and are consequently much more liable to receive attention than when these parts are inaccessibly located.

The regulating valve and the trip valve are entirely separate, but the housing for both valves is cast integral with the steam chest. This eliminates a number of joints that would exist if separate valve bodies were used.

The support of the turbine has also been located near the center line so that sudden changes in temperature will not affect the alignment. This is particularly important in turbines operating at high temperatures.

The auxiliary turbines can be furnished with steel casings. Fig. 66 illustrates a standard turbine of this type direct connected to a 950 gal. per min., 800 lb. per sq. in. boiler feed pump. The turbines are provided with large internal clearances.

A turbine driven circulating pump is shown in Fig. 67. This turbine is designed to operate with steam at high pressure and temperature.

Several direct current, geared, generating units of capacities as high as 6000 kw. were placed in operation during the past year. These units are of the compound geared type and of a construction similar to that used on the house turbines in the Trenton Channel plant of the Detroit Edison Co.

With high temperatures and superheats, the use of the compound turbine is very desirable as the high pressure, high temperature steam can be confined in a relatively small, steel turbine casing.

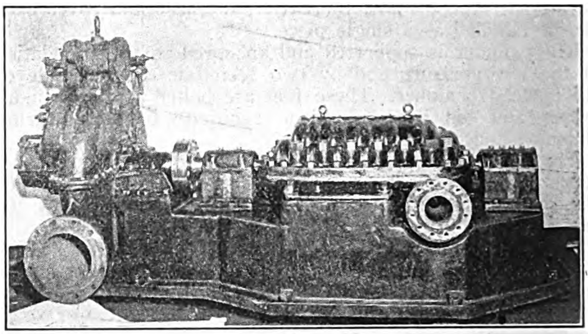

FIG. 66—STEAM TURBINE, DIRECT CONNECTED TO 950-G.P.M., 800-LB. BOILER FEED PUMP—DE LAVAL STEAM TURBINE CO.

STATEMENT BY THE GENERAL ELECTRIC CO., SCHENECTADY, N. Y.

Small turbines are used for auxiliary drive as well as motors supplied with current by low voltage generators coupled to the shaft of the main unit. The difference in overall economy between one system and the other, taking into consideration the fixed charges, as well as the thermal economies, is so small that the final decision as to which system should be used can be made for one or the other depending upon the particular cycle employed or the assumptions made.

Since the statement in the 1927 report this company shipped three 2500 kw. and one 4000 kw. quick starting turbo-generators that are used as standby units for the service generator connected to the main unit. These turbines are non-condensing and are arranged to come to full speed and full voltage from a cold stationary start in a period of

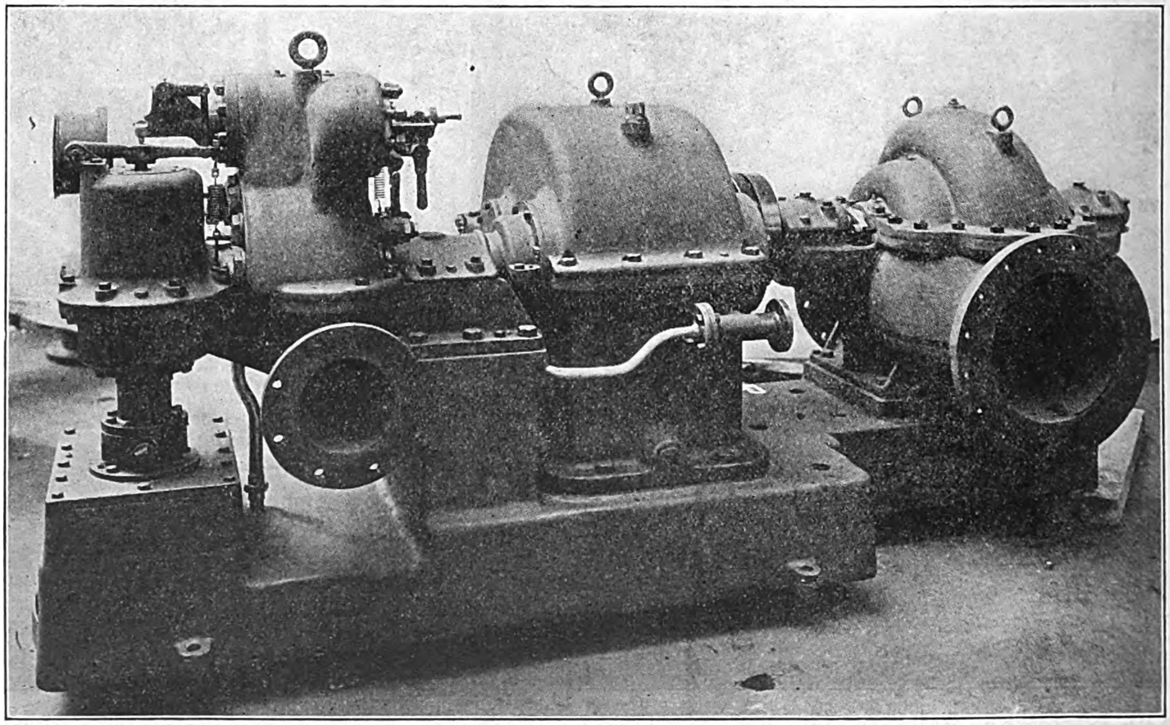

FIG. 67—GEARED TURBINE DRIVING CIRCULATING PUMP—DE LAVAL STEAM TURBINE CO.

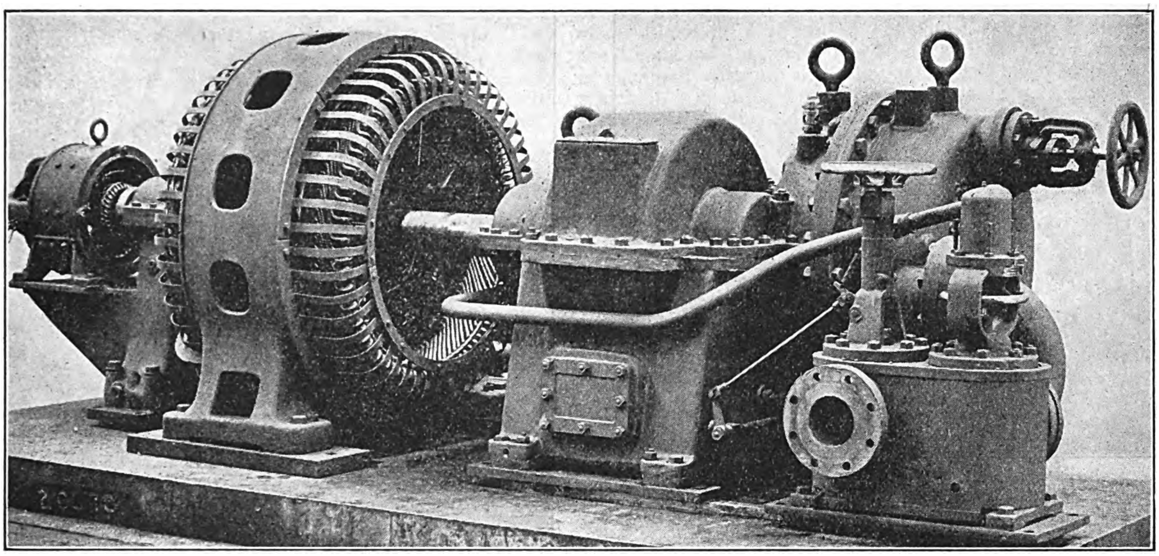

FIG. 68—HIGH-SPEED, GEARED, SINGLE-WHEEL, IMPULSE, REENTRY TYPE TURBINE—WESTINGHOUSE ELECTRIC & MFG. CO.

less than 15 seconds. The turbines can also operate as synchronous condensers, ready to pick up the auxiliary load as soon as the frequency on the system falls below a predetermined value.

Low voltage generators coupled to the shaft of the main unit for driving station auxiliaries are used in a large number of present day plants. This keeps the operation of the station auxiliaries quite separate from the main transmission system and the effective size of the main generator is not reduced, as is the case when the auxiliaries are driven from the main generator. The service generator can be installed without increasing building dimensions, since the space required for drawing the field of the main generator is always longer than the house service generator with its exciter.

STATEMENT BY THE MOORE STEAM TURBINE CORP., WELLSVILLE, N. Y.

This company is prepared to build turbines in capacities from 100 kw. to 2000 kw. with bleed connections at several stages of the turbine for use with stage water heating. These turbines, operating on a highly efficient cycle, may be arranged to use either high pressure or low pressure steam or both and generate power in proportion to the water heating requirements.

These turbines offer a means of increasing the thermal efficiency of stations not fully equipped for stage bleeding of the main units. In some new installations they deserve consideration as a possible alternate to bleeding of the main turbines because of the lower cost and favorable cycle efficiency. Control devices can be furnished to suit conditions.

This company has turbines with integral, helical reduction gears to drive slow speed apparatus and can equip these drives with hydraulic type, variable speed governors if so desired. The standard reduction gears have also been extended to cover the full range of turbine capacities.

Variable speed governors of the hydraulic type can be applied to any turbines when desired, giving a speed range up to about 10:1.

An auxiliary drive unit of a type suitable for use with stokers is built by this company. It consists of a turbine and worm gear combined, having a wide range, variable speed hydraulic governor.

The efficiency of the smaller multi-stage turbines of this company has been greatly improved during the past two years. Much better economy is obtainable by using multi-stage turbines rather than single stage turbines for driving auxiliaries of the boiler feed and circulating pump type.

STATEMENT BY THE TERRY STEAM TURBINE CO., HARTFORD, CONN.

During the past year, no radical changes were made in the design of the steam turbines and reduction gears. The efforts have been directed mainly toward increasing the efficiency of both the single stage and multi-stage turbines and now machines are available that have a lower steam consumption.

Turbines are also built for auxiliaries requiring special drives. A number of turbines of this type are equipped with new and improved governors. In some cases the governors are of the variable speed design, suitable for a speed range of 1 to 10. Provision can be made to control these variable speed machines from some remote point.

STATEMENT BY THE WESTINGHOUSE ELECTRIC & MANUFACTURING CO., EAST PITTSBURGH, PA.

The standard turbines for auxiliary drives can be divided for convenience of description into two types or groups, both of which embody unusual features of simplicity and reliability.

High Speed, Non-Condensing Type

This unit consists of a single wheel, impulse reentry type turbine which is connected to the driven apparatus by a reduction gear. It is built in sizes ranging in capacity from 35 kw. to 500 kw. The normal turbine speeds range from 5000 r.p.m. to 8400 r.p.m. thus realizing the inherent advantages of high speed turbines such as better economy, less floor space requirements and less weight per h.p. developed. Reduction gears are available with ratios to give speeds of the driven apparatus ranging from 750 r.p.m. to 1500 r.p.m.

Fig. 68 and 69 illustrate this unit. The turbine rotor is overhung on the end of the pinion shaft and the turbine and gear form a compact self-contained unit. The cylinder is of unusual construction in that it is split vertically in a plane normal to its centerline, the outer part being a single casting bolted to a machined surface on the ends of the upper and lower halves of the gear case. Other important features in this design include: centrifugal impeller type oil governor of the same reliability as those furnished on large turbines, rotor restraining feature by virtue of which the rotor cannot rupture the casing in case of accidental extreme overspeeding, self contained ejector lubricating system with ejector motive oil supplied by the impeller mounted on the pinion shaft similar to the systems used on the large turbines, external oil cooler and duplex strainer, standard automatic stop governor and automatic quick closing type throttle valve.

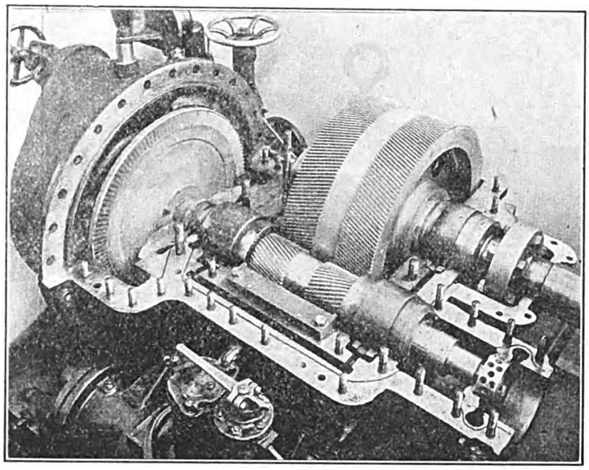

FIG. 69—HIGH-SPEED, GEARED, AUXILIARY TURBINE WITH COVER REMOVED—WESTINGHOUSE ELECTRIC & MFG. CO.

Mechanical Drive Type

The so-called "Mechanical Drive" unit designed primarily as a drive for pumps, fans, etc., consists of a single wheel, impulse, re-entry type turbine which has two bearings and, therefore, constitutes a complete unit. It can be connected to the driven apparatus either directly or through a reduction gear, the method being determined by the class of service. This type is built in sizes ranging in capacity up to 1400 h.p. The normal turbine speeds range from 800 r.p.m. to 4500 r.p.m. and when used with a reduction gear, speeds of 250 r.p.m. to 1500 r.p.m. can be obtained for the driven apparatus.

Fig. 70, 71 and 72 show shop views and a longitudinal section of this turbine. The cylinder base is supported in a cradle-like soleplate in such a manner that it hangs suspended at approximately the center of the turbine shaft. This construction allows the cylinder to expand vertically in either direction from the centerline and eliminates the possibility of this expansion causing any misalignment of the rotating shafts. Other features in this design include: ring-oiled bearings, horizontal weight centrifugal governor, water sealed glands and automatic stop governor.

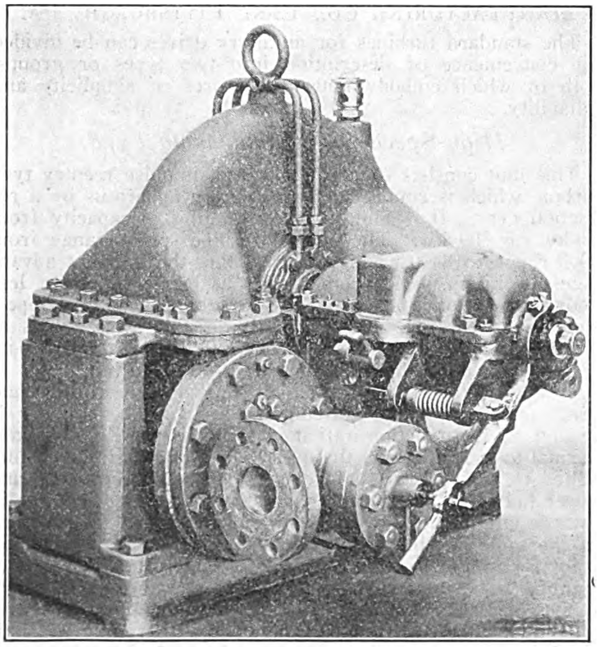

FIG. 70—SINGLE-WHEEL, IMPULSE, REENTRY TYPE TURBINE—WESTINGHOUSE ELECTRIC & MFG. CO.

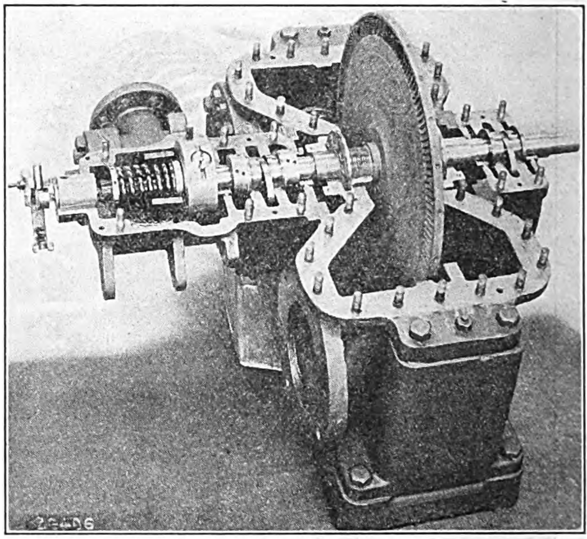

FIG. 71—SINGLE-WHEEL, IMPULSE, REENTRY TYPE TURBINE WITH COVER REMOVED—WESTINGHOUSE ELECTRIC & MFG. CO.

The units described above are built for standard central station pressures and, for special applications, can be designed for higher steam conditions. One application of the mechanical drive type operates with inlet steam at 800 lb. per sq. in. gage pressure and discharges against 150 lb. per sq. in. gage exhaust pressure.

Either type is equally well adapted to dual driven sets and many such applications are now in service. When used for this purpose, it is not necessary to bleed steam through the turbine for cooling as was previously the practice. The governor regulation is such that with proper adjustment the turbine will pick up the load, if the motor speed drops 2 per cent below normal. Also by either manual or automatic control, the turbine speed can be regulated to carry any portion of the load in order to maintain the desired heat balance of the plant.

Another unit which is rapidly gaining popularity as a

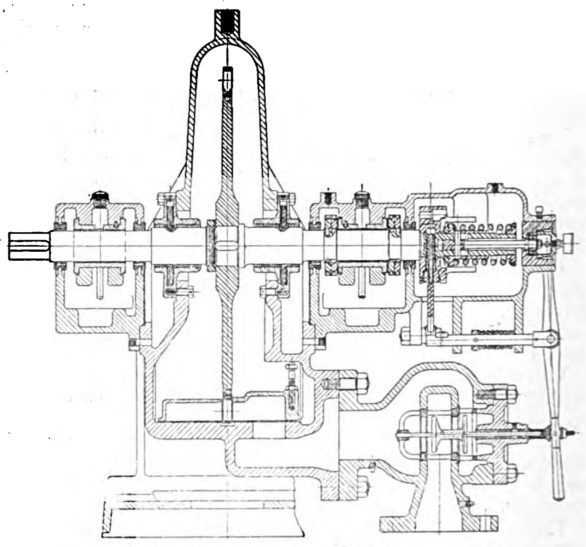

FIG. 72—CROSS-SECTION OF SINGLE-WHEEL, IMPULSE, REENTRY TYPE TURBINE—WESTINGHOUSE ELECTRIC & MFG. CO.

house generator drive consists of a single wheel, impulse re-entry type turbine directly connected to a generator. The normal operating speed is 3600 r.p.m. and it is built in sizes ranging in capacity from 500 kw. to 2000 kw. Due to its extremely sturdy construction, this unit is particularly well adapted to emergency service. In such cases it is either floated on the line or provided with means for unusually quick starting. One unit of 2000 kw. capacity installed at the Richmond Station of the Philadelphia Electric Company is equipped with an automatic starting device by means of which it is brought from a cold, standing condition to full speed in approximately 22 seconds.

Anderson, J. W., and Monteith, A. C. Auxiliary Power at Richmond. Journal of American Institute of Electrical Engineers, Vol. 46, p. 1176-84, Nov., 1927.

The auxiliary system and tests on house turbine generator at the Richmond generating station of Philadelphia Electric Co.

Andrews, R. W. Cost of Turbine Water Rate Increase Power Plant Engineering, Vol 32, p. 1031-2, Oct. 1, 1928.

Anoschenko, B. Increasing Life of Turbine Blades. Power, Vol. 68, p. 590-3, Oct. 9, 1928.

Describes how blading is subjected to controlled vibrations in test machine and the relative life of various forms, materials and system of lashing determined.

Bailey, A. D. High Steam Pressure and Temperature at Crawford Avenue Station. Power, Vol. 65, p. 1008-9, June 28, 1927.

Problems and experiences encountered during two and one-half years' operation. Abstract of paper presented at the 1927 spring meeting of the American Society of Mechanical Engineers.

Blake, A. D. An Unusual Turbine Wreck. Power, Vol. 67, p. 680-2, April 17, 1928.

A 300 kw. turbine failure at United States Department of Agriculture with safety features apparently operative.

Blume, L. F. Characteristics of Interconnected Power Systems. Journal of American Institute of Electrical Engineers, Vol. 46, p. 1365-72, Dec., 1927.

Characteristics as effected by transformer ratio control.

Bodmer, A. Steam Turbine Blading Materials. Power, Vol. 68, p. 692, Oct. 23, 1928.

Results of study and research in turbine blade material.

Brydon, H. B. Some Economic Factors in Power Station Design. Mechanical Engineering, Vol. 50, p. 359-62, May, 1928. Also Power, Vol. 67, p. 925-6, May 22, 1928.

Preliminary layouts of 400, 600 and 1200-lb. plants are shown. The 400-lb. plant was preferred because of simplicity, ease of operation and cost.

Campbell, C. B. The Field and Limitations of the Extraction Turbine. The Electrical Journal, Vol. 26, p. 553-6, Nov., 1927.

Chase, D. D. and Forbes, H. C. Double Winding Generator Solves Breaker Problems. Electrical World, Vol. 92, p. 1183-5, Dec. 15, 1928.

Three plans considered for handling 160,000 kw. units to minimize duty of switches and avoid excessive bus voltage depressions.

Chittenden, J. P. Quick Estimate of Rankine Cycle Efficiency. Power Plant Engineering, Vol. 31, p. 1202, Nov. 15, 1927.

Christie, A. G., and Frank, C. C. Effect of Reheating on Station Economy. Power Plant Engineering, Vol. 32, p. 816-9, Aug. 1, 1928.

Study of the heat economy of various methods of reheating.

Christie, A. G. The Peak Load Problems in Steam Power Stations. Mechanical Engineering, Vol. 50, p. 914-20, Dec., 1928.

Paper deals with problems of annual peak loads in steam power plants.

Clark, F. S. Central Station Practice Shows Higher Efficiencies. Power, Vol. 67, p. 940-1, May 29, 1928.

Coffin, G. S. Toronto Station Doubles Generating Capacity. Power Plant Engineering, Vol. 32, p. 613-20, June 1, 1928.

Collings, F. S. High Pressure Power Station Design in Middle West. Power, Vol. 65, p. 869-70, June 7, 1927. Also Mechanical Engineering, Vol. 49, p. 759-62, July, 1927.

Abstract of a written discussion on paper by V. E. Alden, on present tendencies in steam station design.

Cox, H. A. System Operation of Steam and Mechanical Equipment. Mechanical Engineering, Vol. 49, p. 310-12, April, 1927.

Division of load and maintenance procedure.

Cutting, C. A. Second Hand Turbo-Generator Changes Loss to Profit. Power, Vol. 66, p. 656-9, Nov. 1, 1927.

Example of a change made to an unprofitable plant.

Dougherty, F. S. Is it Necessary to Renew Turbine Oil? Power Plant Engineering, Vol. 31, p. 721-2, July 1, 1927.

Description of turbine oil reconditioning system as used at the Acme Plant of the Toledo Edison Company.

Drabelle, J. M. Automatic Control of Stage Feedwater Heaters. Power Plant Engineering, Vol. 32, p. 662-3, June 15, 1928.

A simple method of controlling temperature of feedwater when extraction turbines are added to plant using open heaters.

Drabelle, J. M. Turbine Tests Show Stage Heater Performance. Power Plant Engineering, Vol. 32, p. 1074-6, Oct. 15, 1928.

Test of 3500 kw. turbine with one stage heater, in which all condensate was weighed.

Drake, C. M. Trenton Channel Plant Nears Ultimate Capacity. Power Plant Engineering, Vol. 31, p. 621-4, June 1, 1927.

Description of latest addition to this plant.

Dunn, C. P. Economy of Interconnection Contracts. Electrical World, Vol. 92, p. 365-6, Aug. 25, 1928.

Benefits of interchange agreements evaluated.

Dunn, C. P. Relation between Steam and Hydro Generation. Electrical World, Vol. 91, p. 799-801, April 21, 1928.

The Electrical Review. A Large High Voltage Generator. Vol. 102, p. 692, July, 1928.

The 22,000-volt generator of the Buffalo General Electric Co.

The Electrical Review. High Pressure Steam Turbines. Vol. 100, p. 523, April 1, 1927.

Turbines installed at Langerbrugge Station, Belgium.

STOKER EQUIPMENT AND FURNACES

Summary

During the past few years there has been a growing tendency on the part of users of stoker fired boiler plants to increase the sizes of stokers and also to increase the input of coal per square foot of grate area. This has brought about the introduction of improvements in furnace construction, in methods of introducing air at the proper place and, in the proper proportion for satisfactory combustion. These tendencies are in line with the real effort on the part of operating companies to reduce boiler plant costs.

Stokers

Experience of member companies, especially with long stokers, has indicated that air distribution has not yet been satisfactorily worked out. Some improvements have been made along this line, and the coming year promises a very marked advance toward the solution of these problems.

For a particular kind of coal the secondary rams or pushers on the long stokers apparently require a different ratio of adjustment from that used on the smaller stokers. To obtain satisfactory operation has, in some cases, required considerable experimental work before the final adjustment was secured. In the future, manufacturers will undoubtedly have more definite knowledge on which to base their adjustment of stokers for a new installation.

Stoker manufacturers have introduced a number of improvements in stoker design during the past year, which are described under manufacturers' statements. These indicate the realization of the importance of continuing the improvement of stoker design to reduce maintenance costs and to increase efficiencies.

Furnaces

Experience of the operating companies with water-cooled walls appears to have been satisfactory and the troubles encountered have been mostly of a minor nature. The use of water-cooled walls has continued to increase along with the tendency to increase furnace combustion rates. An effort is being made on the part of some operating companies to secure a definite comparison of the value of refractory lined as compared to bare water-cooled wall surfaces. Sufficient data, however, are not available at the present time to include them in this report. The manufacturers have continued with an effort to improve circulation in boiler wall surfaces in order to eliminate possible tube failures which might result from improper circulation.

Fans

A number of installations have been made with roller and ball bearings, and while results to date have been satisfactory, except for a few very minor troubles, the companies using them feel that they have not had sufficient operation to indicate the real results.

A very small number of the operating companies report that fans have been tested for performance before installation. Other companies accept the fans as delivered and the only check obtained on performance in many cases is calculated from maximum boiler output test. The inclusion in the contract of a clause calling for shop tests before delivery would tend to eliminate any controversy between manufacturer and purchaser regarding the satisfactory performance of fans, especially in cases where it would be extremely difficult to make tests after installation.

Last year a propellor type fan was developed, for use on a generator cooling system. This fan is capable of developing very high pressures, and can be installed in a comparatively small floor area. However, while they require only a small amount of floor space, their height is somewhat greater than that required by the usual type of fan.

Air Preheaters

The data submitted indicate that there has been continued trouble with corrosion on preheaters, particularly at the exit end of the gas passes. In some cases the trouble has been concentrated on certain portions of the preheater and in other cases it has been general corrosion. The chemical composition of the coal and its moisture content appear to have considerable bearing on this feature. Attention of the operating companies is, therefore, called to the necessity of careful design in the distribution of the gas flow throughout the entire cross-section of the preheaters and also where coals high in sulphur and moisture are used, considerable care should be exercised in the installation and the method of cleaning selected.

OPERATING COMPANIES' STATEMENTS

STATEMENT BY THE BROOKLYN EDISON COMPANY

In connection with the installation of unit No. 5 at Hudson Avenue, four B. & W. cross drum boilers, having 23,764 sq. ft. of heating surface each, and four B. & W. return tubular economizers, with 14,975 sq. ft. of heating surface each, were erected during 1928. In order to reduce slagging alternate boiler tubes being eliminated in the lower row. A sketch of one of the boiler units is shown in Fig. 1.

Bituminous coal with a heating value, as fired, of 13,810 B.t.u. and a proximate analysis as follows:

	Per cent
Fixed carbon	72.5
Volatile matter	19.2
Ash	8.3
Moisture	3.3

is fired on Westinghouse underfeed stokers having 15 retorts and 33 tuyeres. Each stoker is driven by 20-h.p., 250-volt d-c. motors.

Publication No. 289-71, Serial Report, Prime Movers Committee.

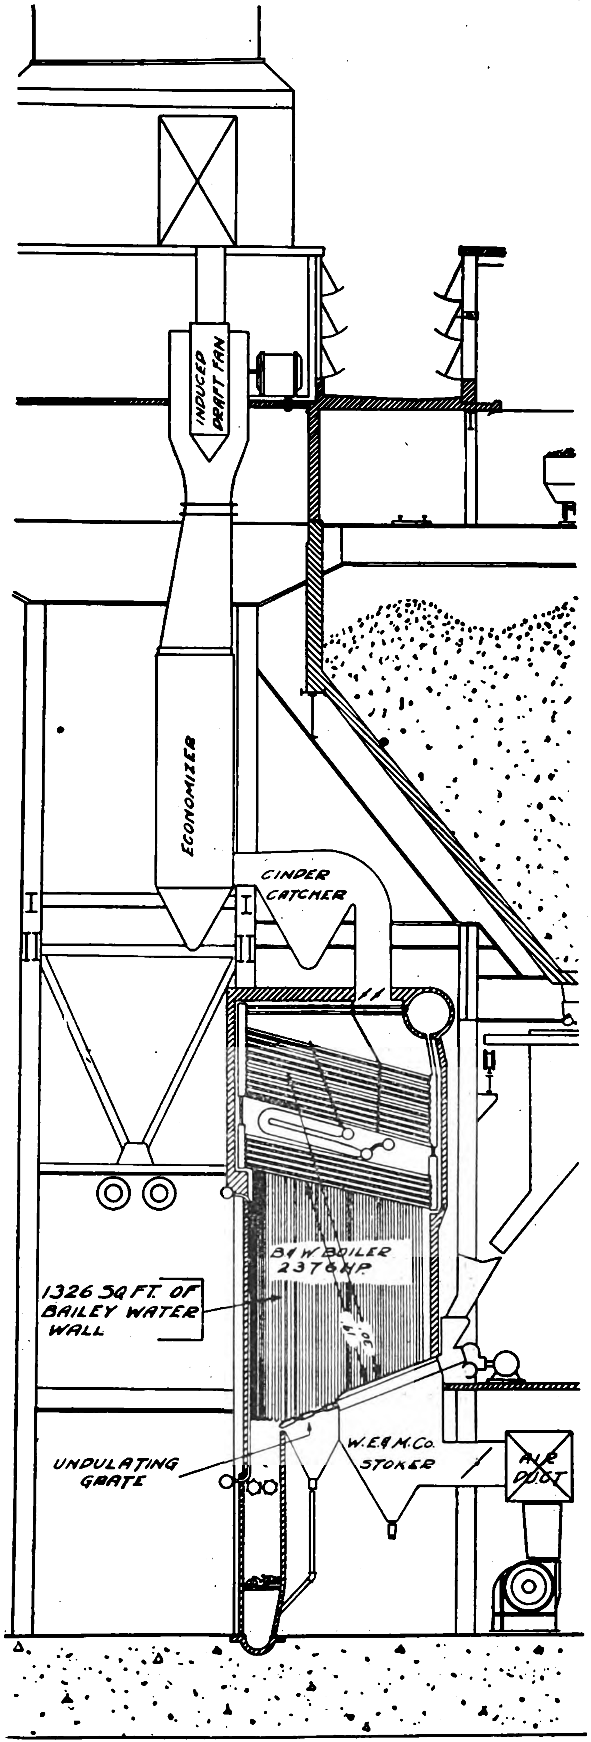

FIG. 1—Boiler Installation, Unit No. 5—Brooklyn Edison Co.

Bailey water walls are used on the sides and rear of the furnace, which has a volume, including ash pit, of 9220 cu. ft. Each side wall has a cooling area of 313 sq. ft., while the rear wall has 700 sq. ft. The walls are covered with bare cast iron blocks in the ash pit and slightly above the fire line on the sides; above this, refractory faced blocks are used.

The forced and induced draft fans are of the B. F. Sturtevant vane control type, motor driven.

Steam is generated at 415 lb. gage at approximately 700 deg. fahr. The maximum rating at which these boilers have been operated is 450 per cent. The stokers and boilers have given satisfactory service.

Air Preheaters

No air preheaters were used on unit No. 5 boilers. With unit No. 4, described in 1927-28 Report of the Subcommittee on Stokers and Furnaces (N. E. L. A. Publication No. 278-49), two Combustion Engineering Company's plate type preheaters, of 21,648 sq. ft. heating surface each, were installed on each boiler. When cleaning the preheaters, the first step is washing down with water while the unit is still hot. An air lance and chain are then employed to remove the caked deposits. Cleaning is done when the boiler is taken off the line after approximately 2000 steaming hours.

Contract curves for these preheaters are shown in Fig. 2.

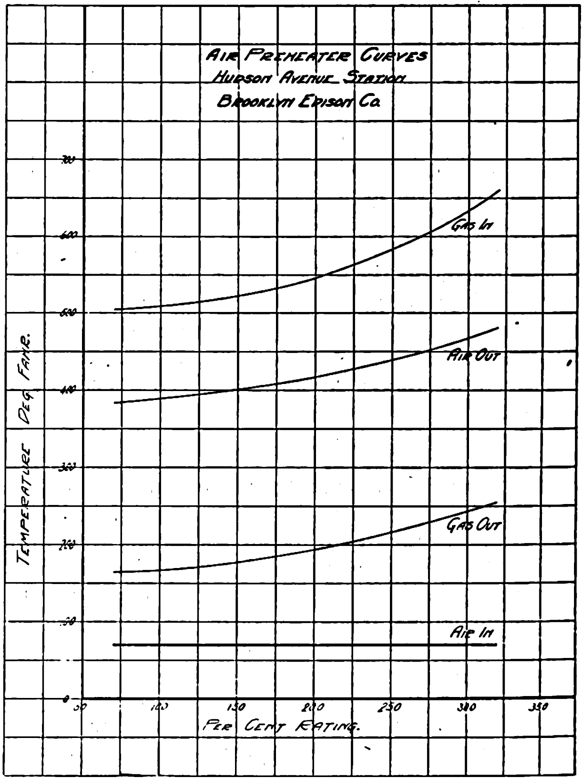

FIG. 2—Preheater Performance Curves—Broooklyn Edison Co.

Statement by the Commonwealth Edison Company

The installation of the last two units (No. 5 and No. 6) at Crawford Avenue Station during 1927 and 1928 involved no radical changes in the steam generating equipment over that of the earlier installations which have been described in previous reports.

The two changes in design as related to combustion conditions were the more extensive use of water screens and more open spacing of the tubes in the lower 3¼-in. tube

bank. The general design of the boiler is about the same as described in the 1926-27 Report of the Subcommittee on Stokers and Furnaces (N. E. L. A. Publication No. 267-59). The increase in the heating surface was due to that added in the form of furnace screens.

The two different furnace screen arrangements are shown in Fig. 3 and 4. Previous experience on trial screen installations indicated the necessity of extending the side screening so as to protect a part of the side wall below the arch. This required a short screen as shown, but connected into the circulation of the main side screen. The effect of this screen system gave such gratifying results in reducing furnace maintenance costs that it was decided to extend the general idea further and completely screen the furnace as shown by the arrangement of Unit No. 6 boilers. The side tubes are more closely spaced (6-in. centers) at the primary part of the furnace as the service is particularly severe at this point. The curtain wall was also included in the screen arrangement. The horizontal forward portion of this screen serves as the support for a special arch construction. This arch is not water cooled in the sense ordinarily understood. The arch blocks are supported by iron clips clamped to tubes and extend only for the horizontal distance, thus retaining the heat radiation function of the arch so necessary to chain grate operation.

Except as stated, screen tubes are all on 9-in. centers and covered with tile to fit. The refractory facing soon erodes due to the action of slag. The tubes, however, are rarely exposed to direct action of the furnace as they are more or less protected by adhering slag. When the brick erodes between the tubes to any extent these spaces are gunnited.

Ample recirculation has been provided for in these screen systems to avoid possibilities of stagnation of flow. Since the installation of these recirculators no failures have occurred.

The increased vertical spacing of the lower boiler tube bank has made this portion of the heating surface more accessible and this facilitates the cleaning and rodding out of the slag deposits. These boilers are usually operated for 35-day periods, which means that frequent rodding and water lancing is necessary to keep passages clear. The cleaning of boilers, particularly as it applies to the lower bank and superheater, still remains one of our main difficulties in boiler room operation. These conditions are, of course, largely due to the character of the fuel. Rather a rapid decrease in boiler efficiency occurs during an operating period in spite of rodding and soot blower cleaning.

The use of preheated air has been the cause of faulty operation and increased maintenance on our chain grates. The apparent limit appears to be about 300 deg. fahr. The cooling of the chain by rear water-cooled drums has met the situation fairly well, but much exists that is still unsatisfactory. Local heating of the chain with resulting "streaking" still persists. This condition can be minimized by draft regulation, even distribution of coal and increased air spacing, but none of these has resulted in a final satisfactory solution of this problem. Trougle has been experienced with the "growth" of cast iron links, necessitating removal of several rows to accommodate expansion. We have made it our regular practice to use steel drive links to eliminate tearing due to jamming.

Turbulence is produced in the furnace by means of overfire air injection. This has resulted in increased efficiency and has reduced smoking considerably. This also has the effect of reducing flame travel where, if turbulence were not used. flames would extend well into the second pass. Under normal operation at average capacity the flame tips out at the inter-deck superheater. Slagging begins to be serious at ratings above 200 per cent, which is lower than plant requirements.

The removal of the compartment siftings by means of screw conveyors proved unsatisfactory. Much better operation is now being obtained by means of the star dumping arrangement which drops sifting to the return chain and to be eliminated through this chain as it rounds the sprockets at the stoker front.

Under normal conditions the operation of the preheaters offers little difficulty except for the problem of cleaning. Preheaters are cleaned by washing when down. No other means has been found satisfactory. The deposit is generally more pronounced at the entrance.

No particular innovations in fan equipment have been made except the use of one forced draft and one induced draft fan instead of two per boiler. Draft control is accomplished by push button with auxiliary control by hand damper.

STATEMENT BY THE LUZERNE COUNTY GAS & ELECTRIC CORPORATION, KINGSTON, PA.

A cross-section of one of the Hunlock Creek 17,260 sq. ft. B. & W. boilers designed to burn steam sizes of anthracite coal, is shown in Fig. 5.

The front and rear arches are so designed that the rich gas rising under the front arch and passing to the throat is met by the lean gas and excess air coming from under the rear arch, in a blast which is strong enough to thoroughly mix the gases at the throat.

After passing through the throat and rising, the gases are again mixed and rolled over by the right angle direction change provided by the horizontal baffle, which extends across the bottom of the second and third passes, and is supported by the second row of tubes. The first and second rows of tubes are separated from the third row in order to form a slag screen.

The boiler was set backwards in order to provide the change in direction of gas flow, since this design has been found to be very efficient in another somewhat similar installation. This horizontal baffle provided a protected third arch effect, with very low maintenance costs. Some other companies had previously used a similar scheme except that the arch was built into and supported by the furnace wall and was located below the boiler tubes. This arrangement resulted in excessive maintenance costs and was, therefore, not satisfactory.

It has been found in the operation of the Hunlock Creek boilers that the gas is so thoroughly mixed at the throat that the third arch is not required except possibly at very low ratings. It is probable, therefore, that future installations in this plant will be made without the third arch and with the boiler turned in the opposite direction to facilitate cleaning and removal of cinder.

The average yearly maintenance cost of furnaces per ton of coal burned since their installation is as follows:

1926	$0.005
1927	0.062
1928	0.023

The above are based on tons of 2000 lb. The year 1926 is not a normal average. During part of that year operation and some maintenance work were carried on by the manufacturer.

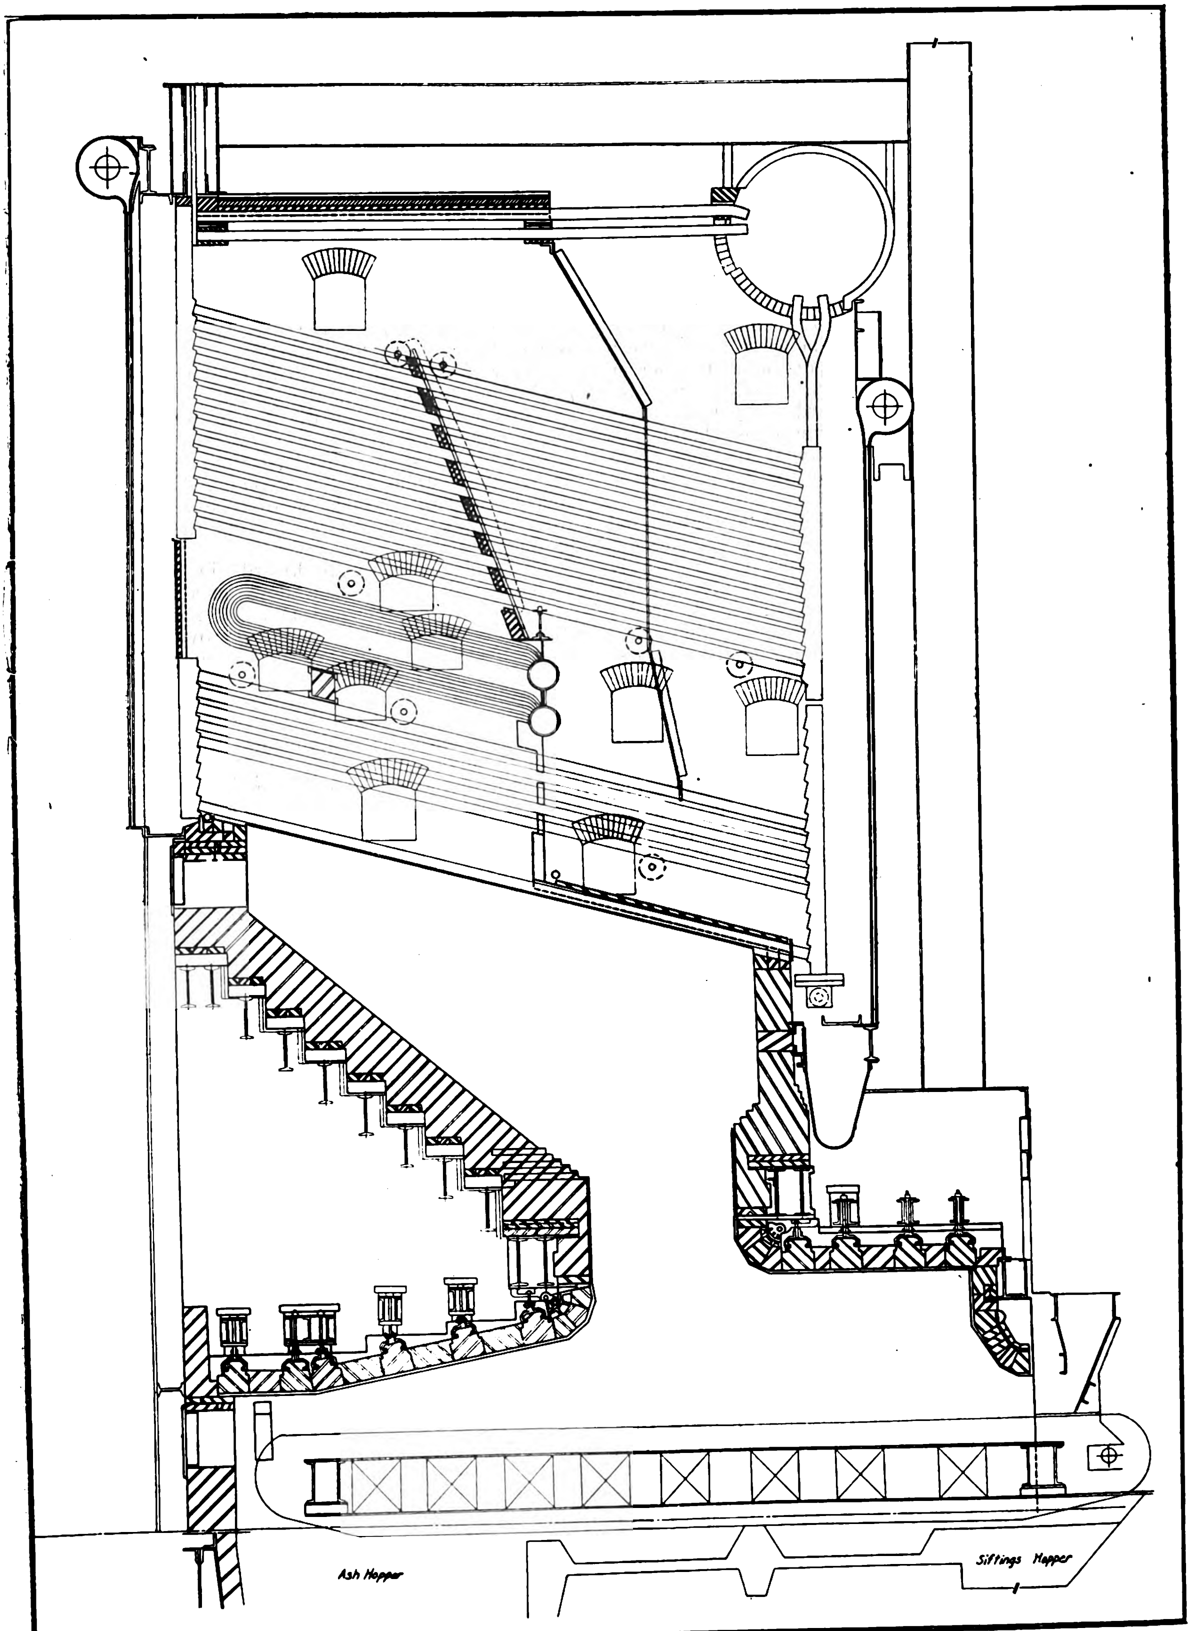
STATEMENT BY THE PHILADELPHIA ELECTRIC COMPANY

Richmond Station

In the 1927-28 Report of the Subcommittee on Stokers and Furnaces a figure of $25 per year per boiler was given for maintenance of the Bailey water-cooled wall blocks at Richmond Station. While this figure is still very low, it has increased somewhat during the past year so that taking the complete period of operation of approximately three years, the maintenance cost is now slightly over $30 per boiler per year. The repairs or replacements have been practically all confined to bare blocks located at the clinker line in the side walls. The original blocks installed were rolled steel, and these have been replaced by cast iron. Up to the present time none of the cast iron blocks has given any trouble, although some of them have been installed for more than a year.

Willow Station

The Willow Station is a central heating plant in which are installed three B. & W. cross drum boilers, each having



Ash Hopper
Siftings Hopper

FIG. 5—CROSS SECTION OF BOILER UNIT—HUNLOCK CREEK STATION—LUZERNE COUNTY GAS & ELECTRIC CORP.

a heating surface of 11,296 sq. ft. Bailey water-cooled walls are installed on the complete surface in two sides and the rear wall. The front wall over the stoker is of standard firebrick construction. Bituminous coal is fired by Taylor 7-retort, 41-tuyere, underfeed stokers.

With the original arrangement of air supply to the stoker it was impossible to secure the expected rating without experiencing serious difficulty in burning out of tuyeres on the lower end of the stoker and with very excessive smoking at about two-thirds of the guaranteed maximum rating. There was apparently too great a jet action by the direct impact of air at the lower end of the stoker. This, combined with the original adjustment of the pushers, caused the fire to thin out at the lower end and frequently resulted in bare places on the stoker. Baffles were installed in one of the stokers, and after considerable experimenting with various locations, a satisfactory arrangement was finally worked out. The work with the baffles was carried on parallel with various adjustments to the pushers so that before the end of the first season's heating load, it was possible to carry the maximum load on the boiler with the experimental baffle. Permanent baffles have now been installed which, it is believed, with the adjustment of the pushers, will solve the difficulties, so far as capacity and smoking are concerned. Fig. 6 is a sketch of the boiler installation, and Fig. 7 illustrates the arrangement of the baffles used for obtaining better air distribution.

FIG. 7—STOKER WIND BOX BAFFLES FOR AIR DISTRIBUTION—WILLOW STATION—THE PHILADELPHIA ELECTRIC CO.

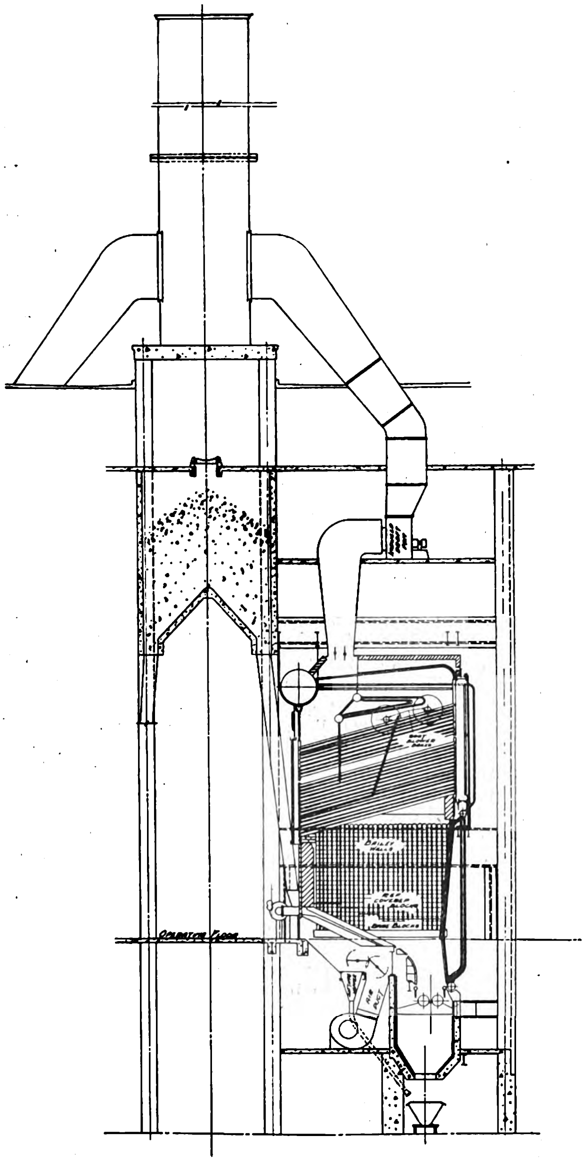

FIG. 6—BOILER INSTALLATION—WILLOW STATION—THE PHILADELPHIA ELECTRIC CO.

The water walls consist of refractory covered blocks, except for the portion extending along the line of the fuel bed. At this point the blocks are of bare cast iron construction. The only trouble has been with certain exceptionally large cast iron blocks which were secured to the lower side wall headers. Several of these blocks burned excessively on the thicker part of the casting and also cracked at the point of minimum thickness. The manufacturer has replaced some of them with a new design which is filled in on the surface of the block at the points where the metal is excessively thick, with a refractory surface. This new design has shown considerable improvement over the orig-

inal, but they have not been in use for a sufficient period of time to form a definite conclusion.

Water Wall Maintenance

Table I gives the total maintenance expense from the time of installation to Aug. 15, 1928, for water walls in Richmond, Chester and Willow Stations. Attention is called to the maintenance cost for boiler No. 8 at Chester Station. While this boiler had a shorter period of service than boiler No. 7, there is almost a $200 maintenance charge for the walls as compared to no cost on No. 7. A probable explanation is that the brick work adjacent to the edge of the water-cooled wall has spalled and eroded to such an extent that the edge of the blocks was exposed to the furnace and the additional heat from exposure of two surfaces of the block could not be transmitted to the water tubes rapidly enough to prevent burning along the edge. The above figure includes some cost for replacing brick work which was removed to allow access to the blocks.

At Willow Station no cost is shown for maintenance of walls although a few blocks have failed and were replaced by the manufacturers.

STATEMENT BY THE WEST PENN POWER COMPANY

During the year 1924, eight 16,400 sq. ft. B. & W. boilers and two 35,300-kw. turbines were installed at the Springdale Station. These boilers are all equipped with 10,700 sq. ft. steel tube economizers. Fourteen retort Westinghouse stokers with 27 tuyeres per retort were installed under seven of these boilers. During the year 1926 an additional turbine of 47,100-kw. capacity was installed without additional boilers. This gave an installed main turbine capacity of 167,000 kw. based upon the manufacturers' ratings.

With twelve of the thirteen boilers in the station in operation at maximum advisable capacity, an average output of only 140,000 kw. can be maintained over the daytime period. This is the base load plant of the system. As the installed turbine capacity is considerably in excess of the boiler capacity, the boilers have been operated so as to obtain the highest possible yearly output without excessive increase in maintenance.

Difficulties Resulting from Type of Coal Used

The coal burned in these boilers is obtained from a mine located at the power station. The coal is very friable and is considerably broken up by the time it reaches the bunkers, giving a very large amount of fines. The fineness of the coal, together with its tendency to soften before the carbonization takes place, makes it very difficult to burn efficiently. Trouble is experienced due to the tendency to coke on the stoker, thus restricting the flow of air. As a result, most of the air passes through the fuel bed along a line just above the ridge of tuyeres where deep furrows are burned into the fuel bed, while the coal in the retort is fused into a solid pencil which is not broken up until it reaches the agitator section of the stoker.

Excess air enters the furnace along the ridge of tuyeres, since it is difficult to keep the tops of the tuyeres adequately covered with fuel. Due to the coking of the coal in the retorts, more coke reaches the overfeed section than can be efficiently burned. The high average resistance of the fuel bed, together with the thin covering of the tuyeres, results in a large number of small particles of coke being blown from the fuel bed. These flying particles settle mostly on the overfeed section and tend to increase the amount of coke to be burned on this section or in the clinker-grinder pit.

The ash in the coal contains approximately 13 per cent of iron oxide, and the fusion temperature is 2350 deg. fahr. Large quantities of coke and ash are blown from the fuel bed against the rear furnace wall. These particles stick and fuse, and the resulting slag flows down the wall at temperatures in excess of 2500 deg. fahr., forming a shelf just above the air box castings in the rear wall. This shelf throws the air away from the surface of the rear wall, and as a result the temperature of the wall is increased and the flow of slag augmented.

In order to remove accumulations of slag at the base of this wall and to dispose of any large formations in the clinker pit, it has been found necessary to bank each boiler for a period of about one hour every night. During this period, the level of ash in the clinker pit is lowered, if necessary, and the shelf of slag is removed by the use of hooks and bars, together with applications of water. The output of each boiler is reduced below normal for an average period of about 75 min. each night until this process is completed.

It was found that the flow of slag could be somewhat retarded by admitting large quantities of air through the air box castings at the bottom of the rear wall. In order the keep the wall cool enough to prevent the flow of slag, it was necessary to keep the ashes in the clinker pit below the level of the air box castings, so that a maximum of cool air could be obtained and a non-reducing atmosphere could be maintained at the wall surface.

The admission of this excess air resulted in an appreciable loss, and was not entirely effective in preventing troubles from slag. These losses were increased due to the burning of the covers of the air box castings, which allowed excessive quantities of air to enter the furnace at some points.

During the first two years of operation of these stokers somewhat more trouble was experienced with the formation of slag deposits even though the ratings were lower at that time. The improvement in these conditions results mainly from the limiting of the maximum CO_2. This has been accomplished without affecting the average CO_2 values.

The average performance data for the year 1928 are as follows:

Average rating while operating, per cent......	273
Average steam output while operating, lb./hr..	145,000
Average CO_2 in boiler outlet gases, per cent....	11.6
Average temperature of boiler outlet gases, deg. fahr.	655
Average combustible in the refuse, per cent....	28
Average temperature of superheated steam, deg. fahr.	703
Time in service, per cent..................	79.0
Time banked, per cent*......................	5.8
Time out of service, per cent................	15.2
Average efficiency of boiler and furnace, per cent	72.0
Average efficiency of boiler economizer and furnace, per cent............................	79.8

---

*This includes the time when the boiler output is reduced below 25,000 lb. per hr. to remove clinker formations. These boilers are practically never banked except over week-ends.

Rates of Combustion

The average output per boiler for each of the seven 16,400 sq. ft. boilers while in service is 145,000 lb. per hr. This average excludes the time necessary to remove clinker formations. The average output during the daytime of week-days is approximately 150,000 lb. per hr. Outputs of approximately 175,000 lb. per hr. have been obtained for periods of 1 hr. on individual boilers. Although the maximum continuous output is limited to approximately 150,000 lb. per hr., outputs of from 160,000 to 165,000 lb. per hr. could be carried over a 3-hr. daily peak. The rates of combustion corresponding to these outputs are as follows:

	Coal burned per sq. ft. of active grate surface. (Projected surface minus ash pit surface but inclusive of agitator)	Coal burned per sq. ft. of projected combustion chamber area
Average output	62.3 lb. per hr.	44.8 lb. per hr.
Average output during the daily peak period	66.0 lb. per hr.	47.6 lb. per hr.
Maximum outputs obtained for periods of 1 hr	80.0 lb. per hr.	58.0 lb. per hr.

The average output for the 8760 hr. of the year is 115,000 lb. per hr. This corresponds to 217 per cent rating.

Stoker Maintenance

During the past year it was the practice to keep twelve of the thirteen available boilers in service during the three days of the week when the load was the greatest. During two of the remaining week-days, eleven boilers were kept in service. Additional boilers were taken from service over the week-end when the system load was low, to make repairs to the stokers.

During the year 1928 the costs of labor and material for stoker maintenance were $0.02 and $0.052 per ton, respectively. During the same period the labor and material costs for the stokers of the five original boilers were $0.015 and $0.032 per ton, respectively. These boilers have duplex Westinghouse stokers of thirteen retorts and are seventeen tuyeres in length. Nearly all of the castings used in stoker replacements are obtained from a local foundry.

Improvements

During the past year several changes have been made which have resulted in improved operation. The largest gain in efficiency has resulted from the construction of ducts to permit drawing the air from the top of the boiler room. As originally constructed, the air for half of the eight boilers in the second section of the station was taken from the discharge of the main turbo generators; the forced draft fans for the other four boilers were located on the boiler room floor and were arranged so that air could be taken either from outside or inside the building. As it has been found from experience that substantially better results were obtained with the warmer air, air ducts were extended to the top of the boiler house.

These ducts have been in use for only a few months, and data are not available over the full range of outside air temperatures. With an outside air temperature of 0 deg. fahr., an average temperature of 80 deg. fahr. is obtained, and with 40 deg. fahr. outside air an air temperature of approximately 100 deg. fahr. is obtained. All of the air for these four boilers is taken from the boiler room except in the very coldest weather.

A marked improvement in performance has been obtained by the use of castings which are bolted to the bottom of the aprons in the clinker pit. These castings fit under the clinker-grinder rolls and extend from the apron to under the center line of the clinker grinder. Their use results in more even grinding and lessens the trouble experienced with holes forming in various sections of the clinker pit. The clinker pit can also be more quickly filled after having been emptied.

“A connection has been made between the forced draft duct and the ash pit below the clinker grinders. As these stokers have water-sealed ash pits, it is possible to maintain the full forced draft pressure under the ash pits. It is believed that the additional air that is caused to pass upward through the ash pit in this way results in a lowered percentage of combustible in the refuse.

As trouble has been experienced with the burning of air box castings that were exposed to the radiation of the furnace, these castings are now being made with ribs on the unexposed side. The holes in these castings are also being enlarged in the exposed side, so as to give a greater surface of contact with the entering air. As a result of these changes the cost of maintaining these parts has been reduced.

Orifices have been installed in the steam line to the stoker agitator rams, in order to reduce the speed with which they are moved and prevent too great a disturbance to the fuel bed.

Water Walls

As a result of the slagging troubles and consequent heating of the rear wall, it was decided to install water-cooled tubes on this wall in one of the furnaces in order to determine if the cooling of the wall would not result in increased capacity and improved efficiency. A water wall of 4-in. tubes placed on 7⅝-in. centers was installed on the rear wall of boiler No. 8.

This installation was made in the fall of 1926. It has been found that, as a result of this procedure, the slagging troubles, are eliminated. The increase in capacity, however, was not found to be as great as expected. The maximum continuous capacity is limited to approximately 160,000 lb. per hr. When an attempt is made to increase the output above this value, trouble is experienced due to disturbances of the fuel bed and the blowing of small particles of coke over against the rear wall and into the clinker pit. This results in losses due to excessive combustible in the refuse.

The following are average performance figures for boiler No. 8 and for all of the other boilers of the same design during the year 1928:

	Boiler No. 8	Boilers No. 7-14 Inclusive
Average rating while in service, per cent...	284	273
CO_2 at boiler outlet, per cent..............	12.6	11.6
Combustible in the refuse, per cent.........	34	28
Temperature of gases at boiler outlet, deg. fahr.	653	655
Temperature of superheated steam, deg. fahr.	667	703
Efficiency of boiler and furnace based upon 70 deg. fahr. inlet air temperature, per cent.	71.6	71.9

It will be seen that the average rating of boiler No. 8 is but slightly higher than that of the other boilers of the same design. The increase in capacity is approximately proportional to the increase in CO_2, indicating that the amount of gas passed through the boiler is approximately the same. The combustible in the refuse has been increased sufficiently to increase the boiler losses by 1.5 per cent of the heat in the fuel burned. This loss, however, is largely offset by the gain due to the increase in CO_2 percentage. The temperature of the outlet gases is slightly lower in the case of boiler No. 8. If compared at the same rating a still lower outlet gas temperature would have been obtained. The superheaters in these boilers are located just above the sixth row of tubes, and consequently the superheat is greatly affected by a change in furnace temperature. The above comparison indicates that the superheat has been reduced by 36 deg. fahr. as a result of the installation of the water wall.

Approximately the same boiler efficiency has been obtained, although the average rating has been increased by 4 per cent. Due to the effect of the increased CO_2 on the economizer performance, the combined efficiency will be somewhat lower for boiler No. 8 than for the others of the same design. The effect of the 34 deg. fahr. reduction in superheat will be to still further reduce the economy of power generation with steam from boiler No. 8 by slightly more than 1 per cent.

These comparisons indicate that the installation of the water wall has made it possible to obtain 7 or 8 per cent increase in boiler capacity with a reduction in economy of approximately 1.5 per cent. This increase in capacity, especially when accompanied by an appreciable reduction in economy, is not sufficient to justify the installation of water walls in the remaining boilers. The failure to secure appreciable benefit from the use of water cooling of the rear wall was due to the fact that the capacity and economy performance was limited by other conditions than those which could be affected by additional cooling of the walls.

MANUFACTURERS' STATEMENTS

The Prime Movers Committee does not accept responsibility for any manufacturers' statement in this report.

Statement by the Air Preheater Corporation

As a result of an improved form of heating element adapted after about one year of routine work in actual installations, all models of the Ljungstrom air preheater have been redesigned during the past year so that they are now capable of giving the same thermal performance with apparatus having a smaller volume, weight and cost. It, therefore, follows that the installation of this type of preheater in plants operating with low load factor can be more easily justified.

The design of the new heating element differs from the older type in that undulating partition sheets marked "B" in Fig. 8 have been substituted for flat partitions. The undulations in the partition sheet are installed in a transverse direction to the flow of gases, causing an increased turbulence and considerably accelerating heat transfer.

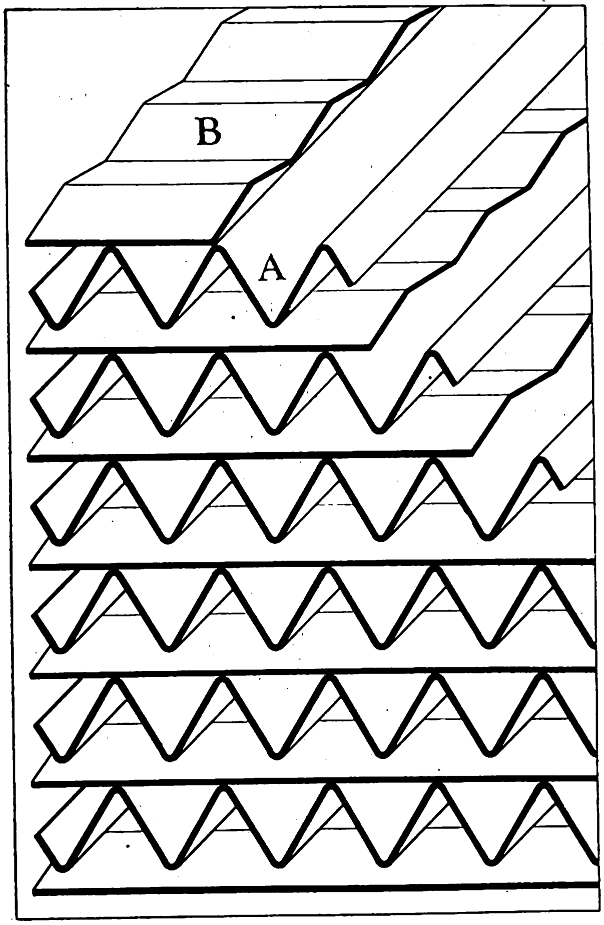

FIG. 8—The New Design of Ljungstrom Heating Surface.

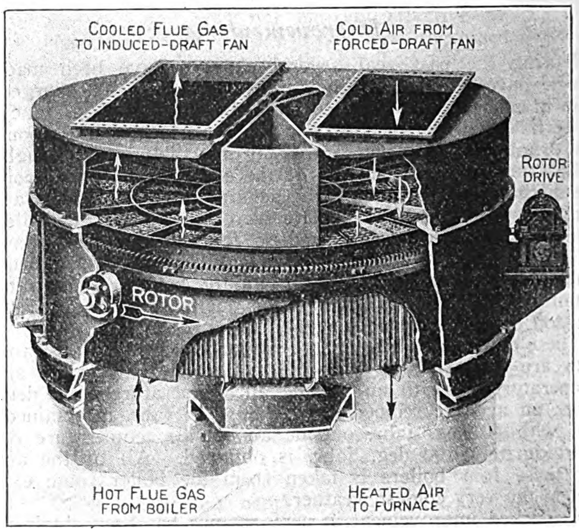
The air and gas channels in this new design have about twice the area of the channels in the older type. This increase in areas, in addition to the greater turbulence, has greatly facilitated cleaning with the simple and effective soot blower provided with the preheater.

Coincident with the adoption of the new type heating element, smaller inlet and outlet chambers were introduced, so that the resulting arrangement requires considerably less vertical space, with no increase in the horizontal dimensions.

The rack and pinion motor drive in all models has been simplified by the substitution of a motor-driven speed reducer for the former chain and sprocket arrangement.

Models up to size No. 16 were formerly provided with a friction drive. All preheaters are now constructed with rack and pinion drives, with the rack made in sections so that it can be easily renewed. The tracks on which the preheaters revolve have also been made in sections, so that they can be readily replaced.



Cooled Flue Gas to Induced-Draft Fan
Cold Air from Forced-Draft Fan
Rotor Drive
Rotor
Hot Flue Gas from Boiler
Heated Air to Furnace

FIG. 9—Ljungstrom Air Preheater for Use with Independent Fans.

Ljungstrom air preheaters are now made in two principal types for use with independent fans and in one type for integral fans. The larger of the independent fan types, shown in Fig. 9, averages about 20 per cent less in vertical height than the corresponding previous model, and the model for use with boilers of less than 10,000-sq. ft. capacity has an overall height scarcely more than that of the rotor. This latter type is the most compact Ljungstrom air preheater ever offered.

The integral fan type, Fig. 10, is now constructed with outboard bearings, which result in much cooler bearing operation and gives greater accessibility for oiling, adjustment and repair.

The fan blades have been altered in design and are now bolted to the hub through plates which are riveted to the fan blading. The fans are so balanced in the new design, and the power input curves for both forced and induced draft fans are such, that working throughout the entire range of boiler ratings the fan driving unit will not be overloaded.

After a considerable experimental period, the air leakage has been decreased by use of sealing strips, illustrated in Fig. 11.

All racks, pinions, tracks, guides and carrying rolls, as well as fan blades are now constructed of steel best suited for the particular service, and a special heat treating department is maintained where the manufacture of these parts is controlled.

STATEMENT BY THE AMERICAN ENGINEERING COMPANY, PHILADELPHIA, PA.

Stokers

The outstanding development during the last year has been the increased use of stokers for large steam outputs and the selection of steam units for greater steam generating capacities. The double-ended Taylor stokers at the Beacon St. plant of the Detroit Edison Company have shown their ability to evaporate half a million pounds of water per hour. They will also put into service this year in their new Delray plant 15-retort, 57-tuyere, single-ended stokers of about the same capacity.

The Taylor stokers firing the high-pressure boilers at the Edgar station of the Edison Electric Illuminating Company of Boston are 16-retorts wide and 45-tuyeres deep.

Abroad equally rapid developments are taking place. The results obtained with smaller Taylor stokers at the Deptford East plant of the London Power Company have been so successful that a second installation of much larger stokers is being made. These new stokers will be 17-retorts wide and 49-tuyeres long. In both cases preheated air is applied.

For the extension to the power system of Berlin, Germany, eight Taylor stokers, 20-retorts wide and 49-tuyeres long, have been purchased. These will be equipped with American Engineering Company water walls and ash handling system. The units, arranged for single-ended firing, will have a capacity of 600,000 lb. of steam per hr.

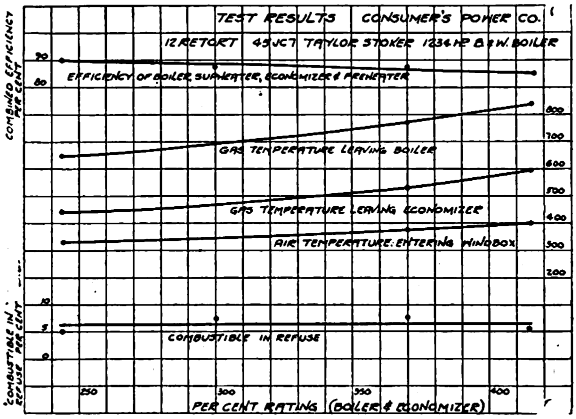

FIG. 12—CURVES SHOWING EFFICIENCY OF TAYLOR STOKER—SAGINAW RIVER STATION—CONSUMERS POWER CO.—ZILWAUKEE, MICH.

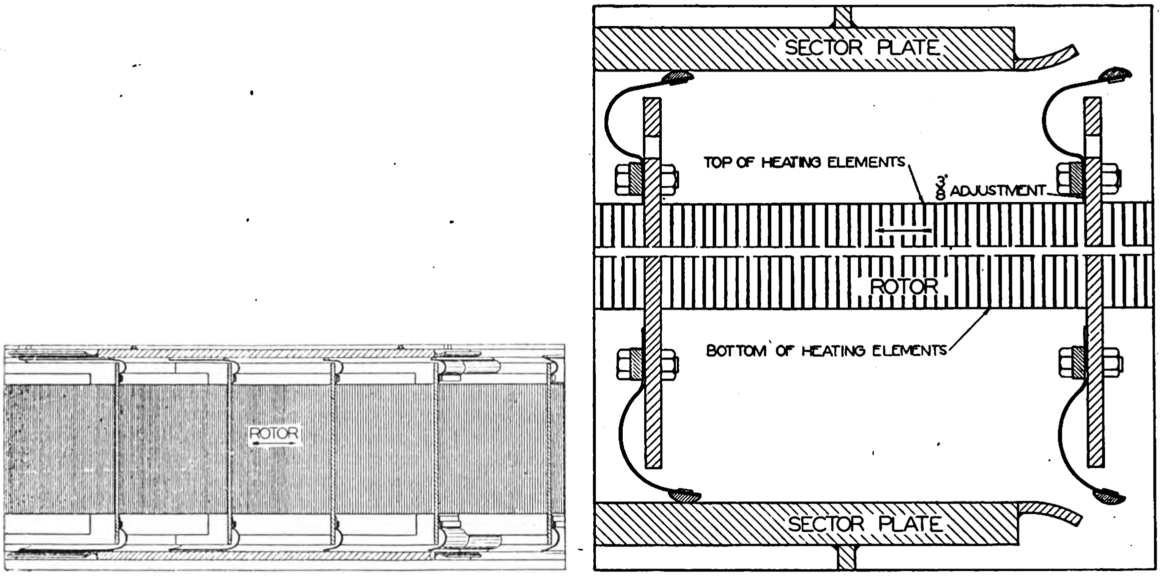
Other stokers of much greater length and width are under consideration. There is no reason why stoker-fired units with a capacity of 1,500,000 lb. of steam per hr. will not be realized shortly.

In spite of the tremendous strides made in generating capacity, efficiency has been maintained. For example, at the Saginaw River Station of the Consumers Power Company, Zilwaukee, Mich., where highly preheated air is used,



ROTOR
SECTOR PLATE

ROTOR
BOTTOM OF HEATING ELEMENTS
SECTOR PLATE

FIG. 11—ARRANGEMENT OF SEALING STRIPS—LJUNGSTROM AIR PREHEATER.

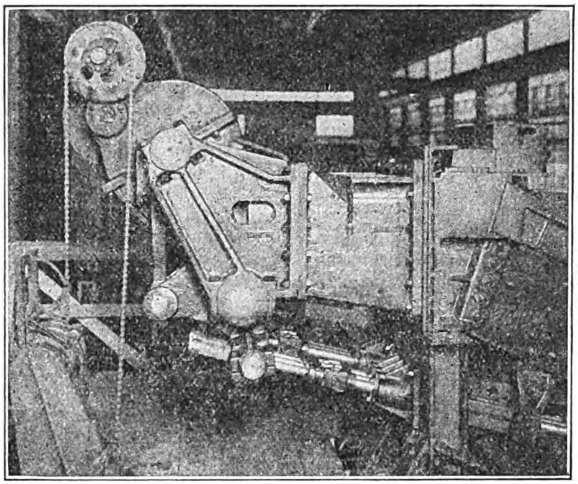

FIG. 13—STRAIGHT LINE MOTION FOR DRIVING RAMS—AMERICAN ENGINEERING CO.

Taylor stokers during a test showed an efficiency of over 84 per cent at 415 per cent of boiler rating, including economizer. The full data are shown by the curve, Fig. 12.

The increase in fuel burning capacity of stokers necessarily involves careful consideration of the mechanical details. The rapid increase in the rate of coal feeding per retort has been taken care of, from the mechanical standpoint, by greatly improved coal-feeding devices, which provide much greater protection from wear than was offered in the small stokers with their much more limited fuel-feeding rates.

Fig. 13 illustrates the straight line motion which is used for driving the rams on the new stokers for the second extension of the Edgar station. Here the drive for the coal feeding ram is entirely independent of the distributing pushers. Moreover, the elimination of the direct connection between the crankshaft and the coal feeding ram eliminates the angular thrust on the ram, resulting in almost complete elimination of the eccentric loading of the ram. It also provides increased bearing surface and greatly prolongs the life of all parts. The same straight-line effect is secured for the pusher drive.

A still further development of this drive is being applied to the 57-tuyere stokers for the Delray plant of the Detroit Edison Company, where the stroke of each individual distributing pusher can be separately controlled.

The large capacities of modern stokers has resulted in a very wide range of steam generation, and boiler ratings from 25 to 500 per cent can now be maintained. The problem of variable coal feed has been met by a number of methods. The electro-hydraulic drive, which has been mentioned in previous reports, has won increased popularity. For smaller plants the direct connected turbine drive illustrated in Fig. 14 is most effective, while the same result can be secured with motor drive by the use of additional speed changing devices. A coal feeding range of 24 to 1 can be obtained with this type of drive.

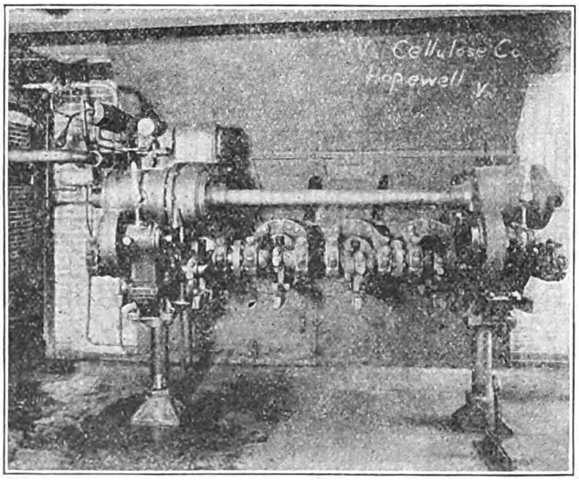

FIG. 14—DIRECT CONNECTED TURBINE DRIVE ON TAYLOR STOKER.

There has been a marked increase in the use of preheat. Practically no large installations now being considered are without this feature. The stokers for the Berlin installation will operate with air at a temperature of 500 deg. fahr., while the stokers for the second extension to the Edgar station will be supplied with air up to 600 deg. fahr., an increase over the previous installation.

Water Walls

The increased rates of evaporation and higher preheat have resulted in the almost universal use of water cooling in the furnace. An excellent illustration of an economic type of wall that provides maximum benefit at minimum cost is that of the new heating plant of the Consolidated Gas & Electric Company of Baltimore, Fig. 15, where the rear wall is completely cooled, while the side walls are protected by a band of cooling along the firing line, thereby eliminating clinker adhesions to the side walls. Fig. 16, a view of the furnace of the Consolidated Gas & Electric Company installation, shows the side walls with the blocks in place on the tubes and the rear wall before the blocks were bolted on. These blocks on the rear wall are carried up high enough to protect the tubes.

Water cooling of the front wall is especially important where the ash fuses at a low temperature and contains a large amount of iron oxide. A complete water cooling of the front and rear walls with the economic type of side wall, has given perfect protection at the plant of the Anglo-Canadian Pulp & Paper Company.

The side wall protection, which has been found very satisfactory, is illustrated in Fig. 17 and 18, where a section three tubes high is shown. Here the brickwork is supported on steel, while the bolted-on blocks of machined cast iron are accessible from the aisle by removing the insulation plates and the plastic insulation immediately back of the tubes.

STATEMENT BY THE COMBUSTION ENGINEERING CORPORATION

Stokers

There has been a definite tendency toward the studied correlation of fuel burning equipment, steam generating equipment and accessories, such as air preheaters and water walls. There is increasing evidence of the advantages of unity of design and responsibility.

Multiple Retort Underfeed Stoker

This new stoker is the outgrowth of many ideas and improvements resulting from years of experience with this machine.

Practically the entire area of each retort is active underfeed area giving even fuel distribution over the entire grate surface. The strength and power of this stoker are self-evident throughout the mechanism and its sturdiness is illustrated in Fig. 19. Parts subject to wear, such as ram box liners, lower section of ram, lower section of ram box and upper section of auxiliary rams, are easily renewable. Likewise, parts subject to burning, such as upper sections of retorts, tuyeres, side wall tuyeres and grate bars, can be easily replaced.

Gear Box

The two-speed gear box is proportioned to the heavy construction of the main part of the stoker and is machined throughout. The hand lever on the front of the gear box

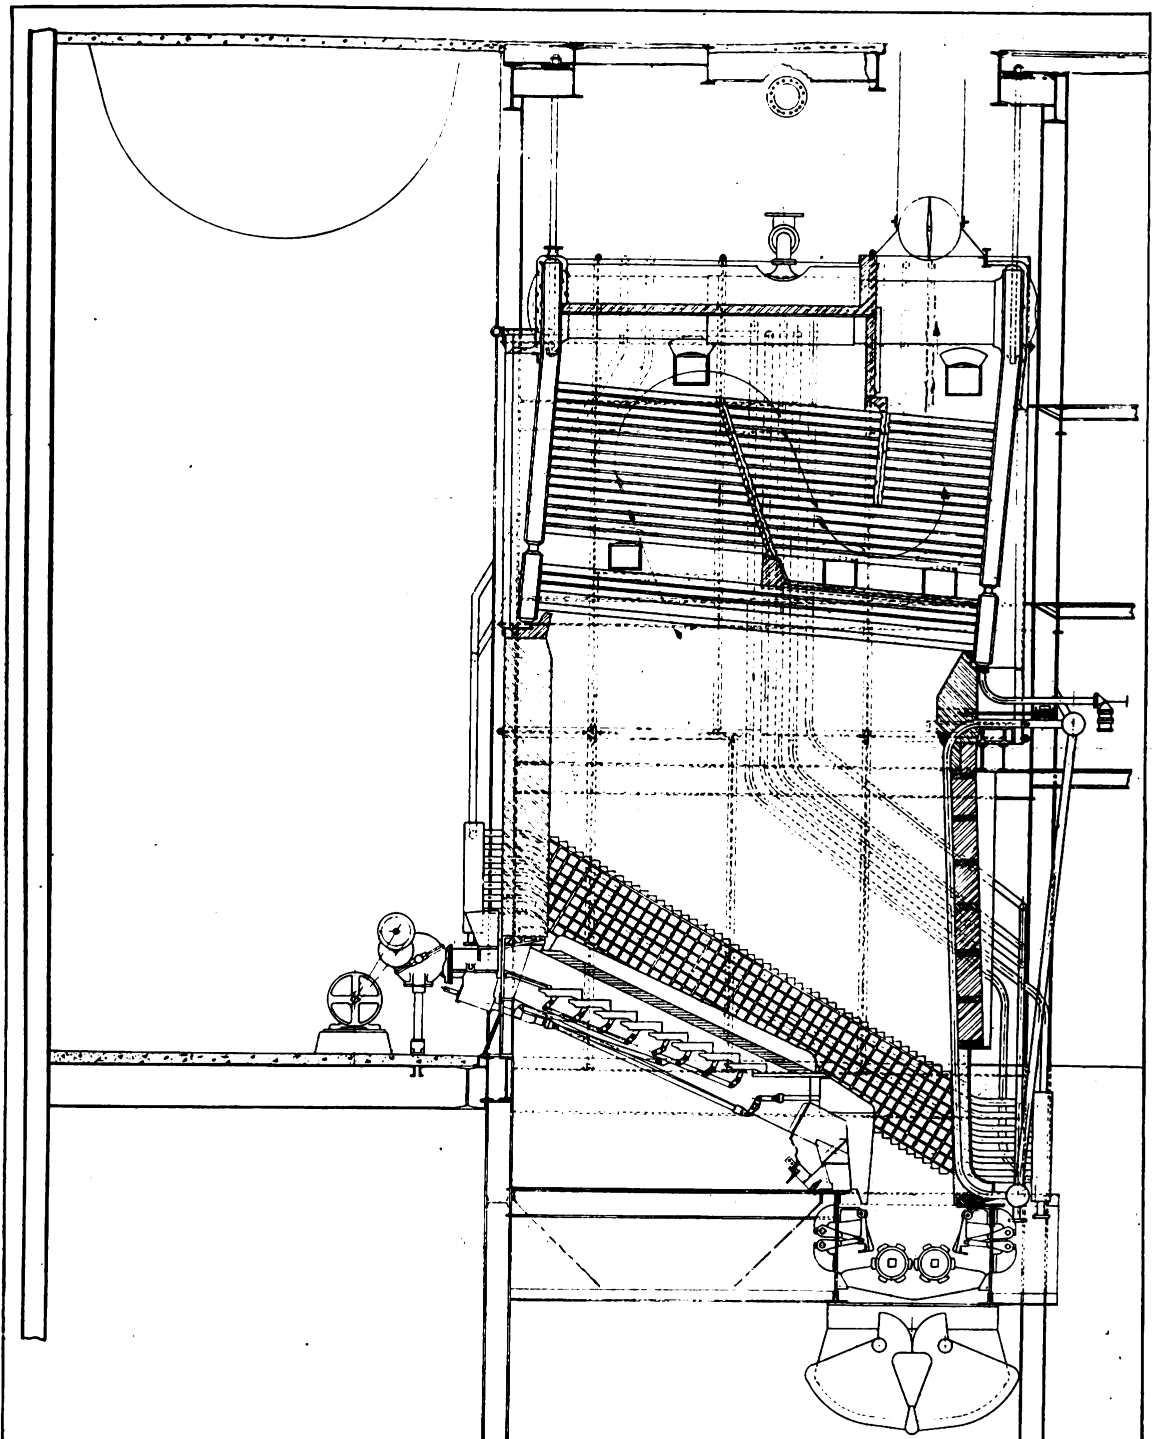

FIG. 15—Water Wall Installation—New Heating Plant—Consolidated Gas & Electric Co.

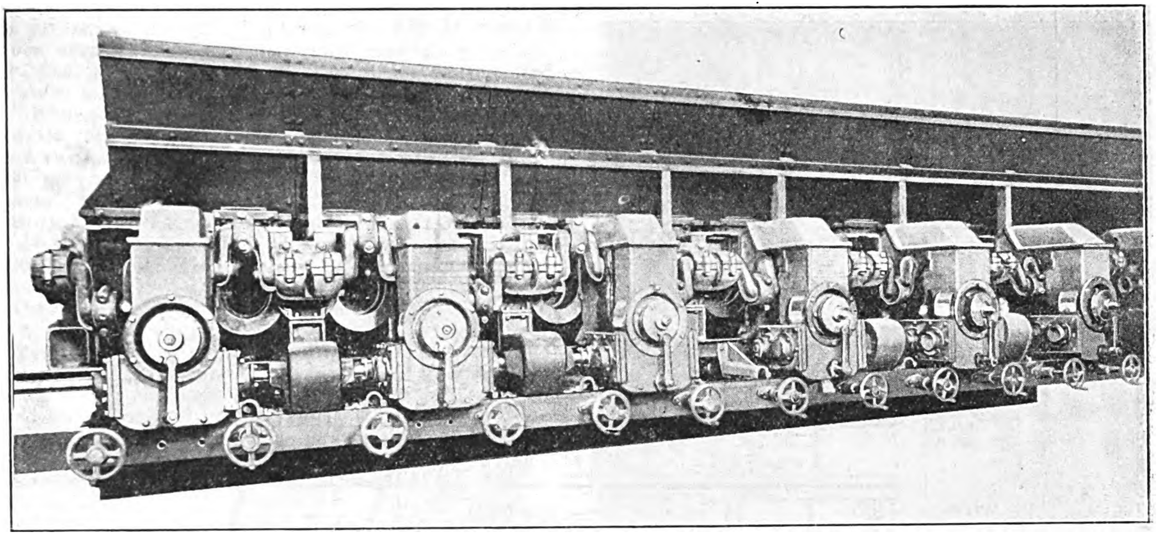

FIG. 19—MECHANISM OF MULTIPLE RETORT UNDERFEED STOKER—COMBUSTION ENGINEERING CORP.

bed when the fresh charge is being forced in and distributes and levels the fuel bed, rather than forming the characteristic furrows usually existing in the fuel bed on an underfeed stoker.

The motion of the grate bars at the end of the stoker is opposite to that of the auxiliary rams, and thus serves to clear the ash from the end of the stoker, so as to be ready to receive the next increment of ash upon the change in direction of motion of the auxiliary rams.

Grate Surface

Each retort is built up so as to provide for expansion and to minimize the possibility of cracking.

The tuyere design gives streamline flow of air and delivers the greater part of the air sidewise into the retort which results in improved operation.

Ash Pit

The ash pit may have either grinder rolls or dump grates. Dump grates are usually installed on the smaller sizes, while clinker grinders are standard for the larger sizes of stokers. These rolls are made up of semi-circular cast iron sections having replaceable teeth and fitted around a square steel shaft which is operated by a pawl and ratchet arrangement. Ordinarily two grinder rolls are furnished in the ash pit, both being reversible and having variable speed.

In Fig. 20, which shows the installation at the Allegheny County Steam Heating Company plant at 12th St., Pittsburgh, Pa., it will be noted that three grinder rolls are installed. This installation represents the first three roll clinker grinder to be built by any company, the arrangement being such that one or both outside rolls can operate separately or in conjunction with the center roll which can operate in either direction.

Front Wall Supporting Casting

The ram box, stoker driving mechanism, hopper and retort sides are bolted to the casting which supports the front wall. The entire stoker body subjected to heat is free to expand and cannot cause any disturbance of the front wall. Also in case of necessary replacement of any parts, the front wall does not have to be disturbed.

Air Control

Zone control of air pressure is afforded by the use of separate air compartments extending across the width of the stoker. The amount of air pressure may be suited to the thickness of the fuel bed directly over any particular air compartment which, with intelligent operation, will result in the best combustion conditions. Without zone control, the air follows the path of least resistance and passes to the lower portion of the fuel bed where it is not needed, resulting in low CO_2 and high flue gas temperature.

Air may be admitted through tuyeres, grate bars, side wall tuyeres and either through dump grates or walls of grinder pit.

The Multiple Retort Underfeed Stoker is recommended for burning all grades of coking bituminous coal, and may be applied to the largest units, as well as those of medium and small sizes. Bituminous coals having high ash content or low fusion temperature of ash are more suitable to burn on chain grate stokers.

Air Preheaters

In respect to thermal performance and lack of operating troubles, the most effective arrangement of air path through the heater has been found to be what is known as the "S" flow, shown in Fig. 21, illustrating the C. E. Air Preheater.

In this design the flue gas flows directly up or down through the heater and the air flows in the opposite direction in an "S"-shaped path, which provides approximately equal length for all air lanes, gives more uniform flow and a more uniform heat transfer rate across the heater.

The latest design provides sectional cleanout doors across the entire heater for the insertion of steam or air lances, which makes it possible to clean the heater during operation.

A further improvement has been made in welding the elements to sealing strips at the air inlet and outlet instead of using bolts, thus eliminating leakage at these points. The elements themselves are electrically welded, as usual.

Water Walls

During the year 1928 little has developed that is new so far as the principles in water wall design are concerned. The most important results of the year's activity are the experiences gained from the performances of different wall constructions under various furnace conditions. The knowledge of causes and effects has been increased so that simplicity in design and certainty of results have greatly increased.

Typical results which have a strong bearing on future

designs are shown in Fig. 22, 23 and 24. Fig 22 shows a bare tube rear wall, backed with solid refractory, as applied to 5120 sq. ft. Edge Moor cross drum boilers fired by the Aero unit system for pulverized fuel. The settings include Foster Bare tube side and rear walls, with air-cooled refractory panels in each side wall toward the front. This is a two-pass boiler for operation at 385 lb. per sq. in. and 300 per cent rating. Fig. 23 shows the same wall construction after several months of operation. Eminently satisfactory results have been obtained.

Fig. 24 shows the side wall of one of the furnaces for the 9000 sq. ft. Edge Moor boilers, as described on pages 70 and 71 of the 1926-27 Report of the Subcommittee on Stokers and Furnaces. The construction of the wall is that shown as "D" on page 69 of the Report and consists of bare tubes to the back of which are bolted wing castings designed to effect the greatest absorption of radiant heat by the tubes. At the right of the picture is the rear wall composed of refractory faced tubes. The relative freedom of the bare tubes from accumulation and its self-cleaning tendency are well shown.

Fig. 25 illustrates the rear wall and portion of side wall during construction of the furnace for 10,150 sq. ft. cross drum Babcock-Wilcox and Goldie-McCulloch boiler. This is a good example of the modification of construction as dictated by experience. Here the side wall and upper portion of the rear wall are of bare tubes with bolted-on wing back castings for the absorption of radiant heat. The unit is fired by Aero unit system and has an air-cooled refractory wall at the front of the furnace. The lower portions of the rear wall tubes are covered with flat faced cast iron blocks, bolted to the furnace side of the tubes. This gives a smooth, virtually indestructible surface to withstand high temperature and the wear of slag removal.

Air Preheaters

The application of the new plate type sectional air heater manufactured by the Foster-Wheeler Corporation constitutes one of the interesting developments in the work of air preheating for 1928. Several of these air heaters are now in operation and are giving highly satisfactory results.

Fig. 26 shows a typical arrangement of four sections of an air heater arranged one above the other so that gases may pass vertically either upward or downward, while air passes horizontally through each section and through all of the sections in series, passing from one section to another through connecting ducts.

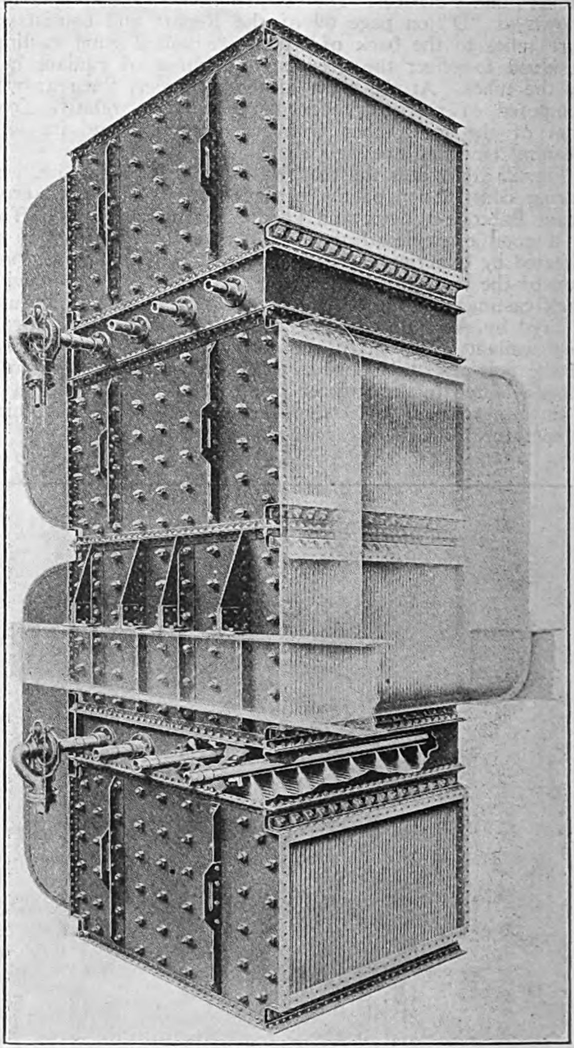

FIG. 26—AIR PREHEATER—FOSTER WHEELER CORP.

The cleaning of air heaters warrants intensive study since the efficiency of the heater depends upon the cleanliness of the surface. A means of cleaning a typical Foster air heater with steam soot blowers placed between two sections is also shown. By revolving the soot blower elements the gas passages in the sections both above and below are cleaned. The soot blower element is then moved longitudinally a distance equal to the space between the gas passages, and the element again revolved. The nozzles are placed five or six spaces apart so that moving the element the proper number of times will clean the full width of the section.

Fig. 27 shows a 51,000 sq. ft. air heater with the ducts partially completed. It should be noted that in this installation the gases pass downward through the air heater so that the lowest sections constitute the cold end of the air heater.

Referring to Fig. 26 it will be seen that should the cold end sections deteriorate from corrosion they may easily be replaced by unbolting at the top; the construction is designed so that this may be accomplished with minimum difficulty.

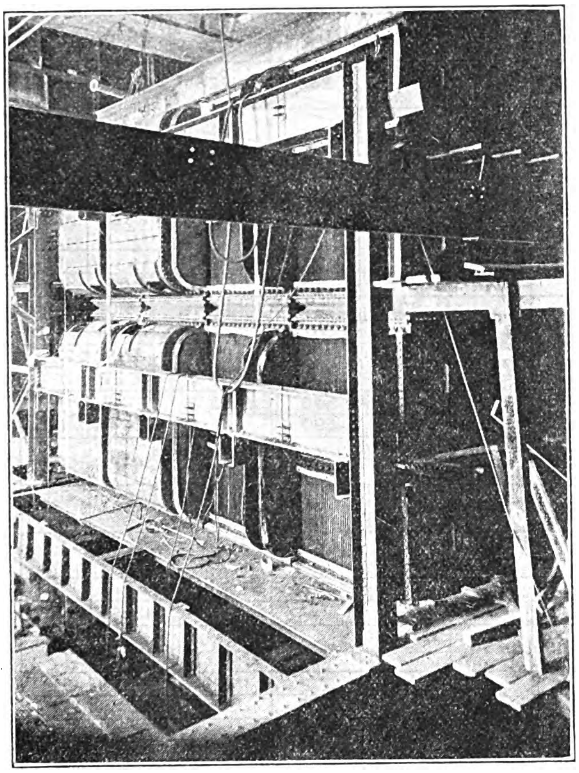

FIG. 27—AIR HEATER DURING CONSTRUCTION—FOSTER WHEELER CORP.

The performance of smaller air heaters in the same plant have given the following results:

Air heater surface	13,580 sq. ft.
Boiler surface	14,086 sq. ft.
Steam production	110,000 lb. per hr.
Flue gases	230,000 lb. per hr.
Air heated	170,000 lb. per hr.
Temperature of air increased from 87 deg. fahr. to 285 deg. fahr.	
Fuel saving effected	6.15 per cent

Fig. 28 shows another arrangement of sections and illustrates the flexibility of design. These air heaters are placed in a low head room. The gases pass up through one air heater section and through a horizontal duct across to the other section and down through the second section to the flue. The air to be preheated enters one air heater section flowing horizontally, is connected by a horizontal duct to the other section and flows through it also horizontally before being discharged to the furnace. This arrangement made it possible to install a moderate size air preheater in conjunction with an economizer where the space was unusually limited.

Fig. 29 shows a line drawing of the boiler unit for the new Holland 1400 lb. station, including five section high air heaters, economizer, etc. In this case there will be two groups of air heater sections each five high, the forced draft fan delivering air to each of the two bottom sections, the air flowing upward through the air heater while the gases flow downward to the induced draft fan.

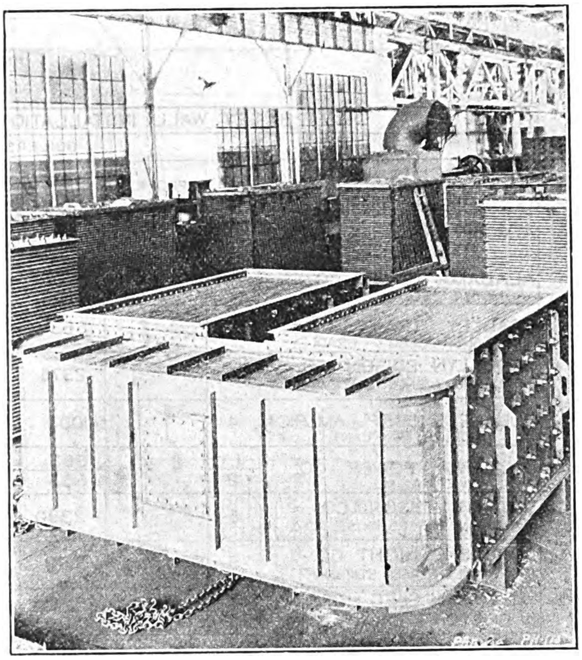

FIG. 28—AIR HEATER FOR LOW HEAD ROOM—FOSTER WHEELER CORP.

STATEMENT BY THE FULLER LEHIGH COMPANY, FULLERTON, PA.

The past year has been one of marked progress toward a better knowledge of the requirements and design possibilities of water cooling of stoker-fired furnaces and also in the number of notable installations placed in service.

For large furnaces operated at high ratings, the probability of brick work trouble or slag dripping down on the

stoker, justifies carrying water-cooled surface over all walls even to the extent of eliminating refractory in the front wall. There are many smaller installations burning coal with a high ash fusing temperature and operating at moderate ratings, where only partial water cooling is justified. A protected tube type of water wall construction which will maintain its protective feature is particularly desirable in the side walls adjacent to the fuel bed and in the bridge wall from an elevation of a few feet above the stoker down into the clinker pit. Table II shows the wide variety of applications of the Bailey wall to stoker-fired boilers.

During the past year, 24 boilers equipped with Bailey walls have been placed in operation and 16 additional units are now in process of design or erection. These units represent practically all of the well known types of boilers and stokers and range in size from 6630 to 31,790 sq. ft. Ten of these furnaces represent repeat orders, placed as a result of favorable experience with previously installed Bailey walls.

In the larger sizes of boiler units the economic desirability of installing the largest possible amount of stoker grate area calls for a type of water-wall construction which is adaptable to local conditions and requirements. Fig. 30 illustrates several examples of the adaptation of Bailey furnace walls to meet unusual physical limitations of boiler and stoker design.

Furnace A is a 1400-lb. installation in which the length of the boiler tubes at the time the job was designed was limited to 18 ft. because of the extremely high operating pressure. Since the width of boiler was limited by the maximum length of drum obtainable, the capacity desired made it necessary to install a stoker of greater length than the boiler tubes in order to obtain sufficient grate surface. This difference in length was accommodated by sloping the Bailey bridgewall to the rear. Complete water cooling was installed in the side walls and the ends of the ash pit in order to insure freedom from clinker obstruction. The bridgewall at its lower end is sloped away from the stoker to provide a diverging passage for movement of refuse to the discharge crusher rolls. An access doorway was provided in each of the water-cooled side walls, by cutting out short sections of certain wall tubes and installing cross headers above and below the opening thus formed. A cast-iron frame and door with refractory lining completes the assembly, which is carried on the pressure-part structure by extended block studs. Small inspection doors are placed at strategic points in the side walls and bridgewall for convenient observation of all portions of the fire.

Furnace B was installed with complete water cooling in the side walls and arches. No difficulty was experienced in designing these arches to obtain the proper primary and secondary combustion zones in the furnace with the proper throat opening between arches. The usual problems of supporting large refractory arches were not encountered with the use of Bailey construction and no limitations were placed on the design on this account. Refractory faced blocks are used on the side walls, the bottom of the front arch, and the noses of both arches. The blocks on the under side of the front arch are a cemented-in type of refractory block which will maintain a high furnace surface temperature to aid ignition. The upper portions of the side walls and arches are of smooth bare metal block construction to reduce the temperature of the gases entering the boiler tubes and decrease tube slagging.

In furnace C it was necessary to obtain the maximum of capacity from a unit limited in size by existing building columns. In order to accommodate the widest possible stoker and to eliminate all brick work from the side walls the water-cooled walls were sloped outward from the top and at this point were made flush with the boiler setting.

Furnace D is an installation where a stoker slightly wider than the boiler at the tubes was selected. This required bending the side walls outward to match the stoker width. Previous experience with the failure of solid refractory front walls on other boilers caused this particular customer to want a water-cooled front wall. In this construction expansion is allowed for by providing clearance at the bottom of the wall which is sealed by a casting attached to the stoker feed hopper. This forms a sliding seal with the square header.

Water-cooled walls have been found to reduce stoker maintenance. This effect is marked on high capacity installations operating with highly preheated air. It has also been found that units operating under these conditions must be handled very carefully; otherwise severe heat conditions may occur at the lower end of the stoker which not only damage the stoker but may also punish any type of furnace wall construction that is installed.

The data given in Table III, which have been collected through the courtesy of operating companies, indicate the low furnace wall maintenance on a representative number of Bailey wall installations on stoker-fired boilers.

*Maintenance caused by tube failure due to scale formation and low water.

The protected tube type of construction is recognized as necessary in all types of water-wall construction where cooling is located in zones of intense punishment such as along the fuel bed and in the lower section of a bridgewall. The T-shaped block which fits between the cooling tubes is used in the Bailey construction. It is a wedge fit between the tubes and when it expands under the temperature conditions of operation, it tends to make a better fit and closer contact with the tubes. When expansion occurs on a block which clamps around a tube it grows away from the tube and tends to destroy any contact. With rates of heat transfer as high as 100,000 B.t.u. per sq. ft., which we have found are sometimes obtained on bare blocks installed on stoker jobs, the life of the block depends on obtaining suitable heat transfer from the block to the tubes which can be secured only by good contact and the use of proper heat conducting bond between the block and tube surfaces.

Furnace wall tubes may undoubtedly be exposed to more severe conditions than boiler and superheater tubes. Due to the location, they are at times subjected to higher rates of heat input per sq. ft. of tube surface than any other part of the boiler unit. These tubes are nearly always vertical so that the steam film, which is formed when heat is applied to water at saturation temperature, persists in following up the hot side of the tube, thereby creating a heat insulating zone of appreciable magnitude. Whenever any scale forming matter is present it is more likely to adhere to the surfaces where the higher rates of absorption are taking place. All of these factors tend toward increasing the temperature of the furnace wall tube for any given steam pressure.

For these reasons it is important to protect the furnace wall tubes against excessively high rates of heat transfer, to distribute the heat to various portions of the tube without high localized intensity, and to supplement further the strength of the tube by armoring it with a block structure which will minimize the danger from this source.

The Fuller Lehigh Company has developed a rough sur-

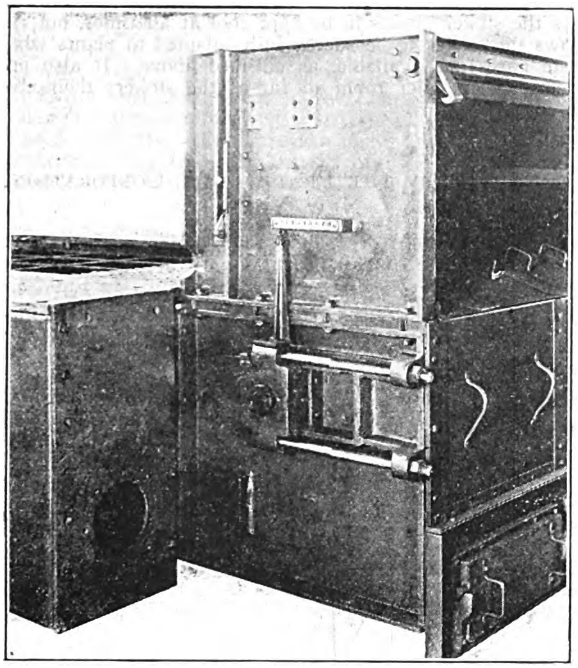

FIG. 31—TAKE UP INDICATOR—ILLINOIS STOKER CO.

faced bare metal block which has been used in place of refractory faced blocks. This block has a ribbed surface somewhat like the surface of a waffle iron to which the fly ash and slag will adhere and gradually build up a refractory coating. For certain conditions this block admirably serves the purpose of the refractory block.

Probably the first water-cooled installation on a stoker-fired boiler burning anthracite screenings was placed in service early in January, 1929, at the Nanticoke plant of the Glen Alden Coal Company. This is a 6680 sq. ft. chain grate stoker-fired Stirling boiler equipped with Bailey side walls. The results obtained from this installation will be watched with interest.

The rehabilitation of old stoker-fired boilers with modern water walls is of some interest. Experience has proved that it is not only possible by this means to reduce high furnace maintenance, but also to increase both efficiency and capacity.

The Memphis Gas & Electric Company installed Bailey bridgewalls on three of the boilers in their Fourth Street plant in April, 1927, to eliminate high furnace maintenance. Prior to the installation of Bailey walls, it was necessary to renew these bridgewalls about every six to nine months. Since that time they have had no maintenance on the Bailey wall and the refractory above the water-cooled portion is protected sufficiently by radiation from the boiler tubes to have required little maintenance.

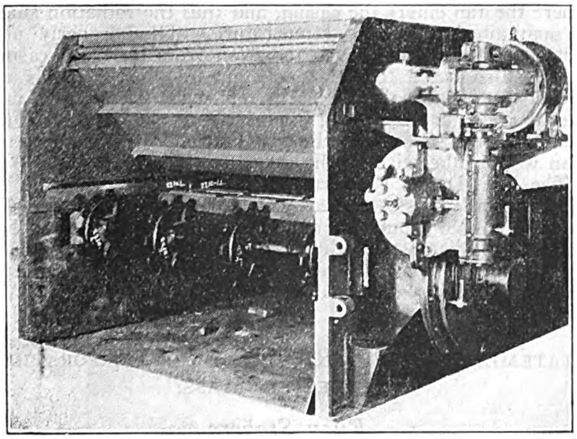

FIG. 32—NEW TYPE DRIVE FOR FORCED DRAFT CHAIN GRATE STOKER—FRONT VIEW—ILLINOIS STOKER CO.

Tests reported by The Philadelphia Electric Company, which were run on their Boiler No. 7 at Chester both before and after the installation of water walls, indicate an increased efficiency after the walls were installed. This difference was of the order of 2 per cent at normal ratings and 5 per cent at maximum ratings of about 12,000 lb. of coal per hr.

STATEMENT BY THE ILLINOIS STOKER COMPANY, ALTON, ILL.

Major Improvements on Illinois Forced Draft Chain Grate Stoker

1. Take-Up Indicator

During the past year the Illinois Stoker Company has designed and applied to its forced draft stokers a take-up indicator for the purpose of checking the alignment of the front drive shaft. Referring to Fig. 31, it will be seen that this feature consists of a cast iron pointer bolted to the front shaft bearing, this construction being applied to both sides of the stoker. A brass scale is attached to the upper part of each stoker head frame. By means of the pointers and scales the operator can at all times easily check the alignment of his front drive shaft and make sure that the two pointers indicate the same reading on the scales. Heretofore there has been no convenient method provided for checking the alignment of the front shaft, and for this reason very little attention has been paid to this point by the operator. If the front shaft is allowed to become out of line, it usually follows that the chain works to one side, or may jump the front sprockets, or various other difficulties, all of which involve the possibility of breakage and shut-down.

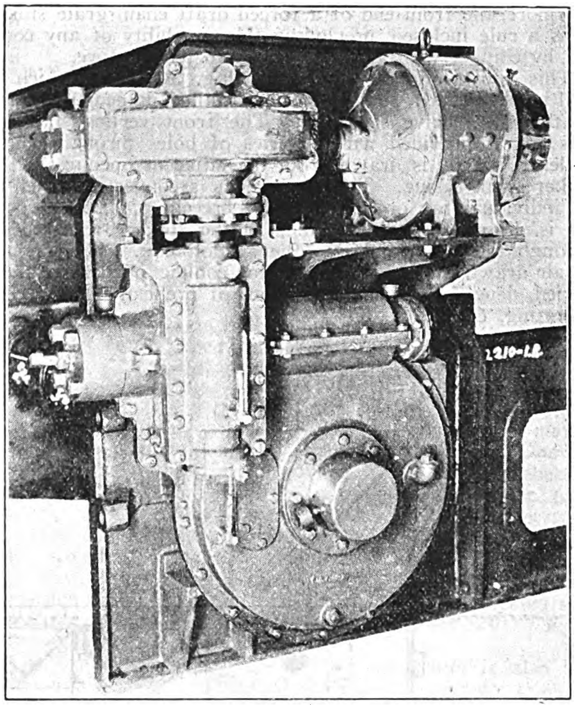

FIG. 33—NEW TYPE DRIVE FOR FORCED DRAFT CHAIN GRATE STOKER—SIDE ELEVATION—ILLINOIS STOKER CO.

With this new feature, it is very easy for the operator to make sure at all times that the front drive shaft is properly lined up.

2. New Drive

This company has developed a new type of drive for its forced draft chain grate stokers, as is shown on Fig. 32 and 33, which consists of three worm and gear reductions mounted in series and driven by a direct connected motor having a wide speed range. The entire drive is integral with the front drive shaft of the stoker, and moves forward or backward as the chain take-up bolts are adjusted. All gears and worms are equipped with cut teeth and are running in oil, and thrust bearings are provided where necessary.

The distinct advantages of this new drive are that it eliminates the necessity of using belts, belt tighteners, chain drives, etc.

3. Chain Cooling

A new system of cooling stoker chains, especially where preheated air is used, recently has been developed by this company. In this type of stoker very little heat radiation escapes from the chain before re-entering the furnace, due to the fact that the chain is subjected to a high degree of heat, not only in passing through the furnace, but also in traveling from the rear of the furnace to the front. Furthermore, the front end of a forced draft chain grate stoker is as a rule inclosed, precluding the possibility of any cooling by contact with air at boiler room temperature.

This construction is shown on Fig. 34, from which it will be seen that a suction box is installed immediately back of the front drive sprockets. The front vertical face of this box is provided with a series of holes through which boiler room air is drawn from the adjacent opening in the stoker front casing. This cross duct is connected either to an individual fan or to the boiler breeching. Boiler room air is drawn through openings in the stoker front casing through the chain and into the suction box. The amount of air drawn through the chain for cooling purposes can be varied, depending upon the amount of preheat, the per cent of rating, etc.

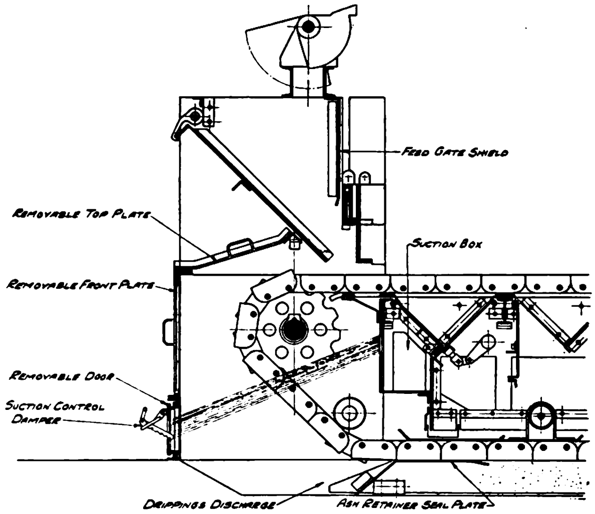

FIG. 34—ENCLOSURE OF FRONT END OF FORCED DRAFT CHAIN GRATE STOKER—ILLINOIS STOKER CO.

In some industrial plants gases having a higher or lower calorific value are made as a waste by-product. It has become common practice to convey these gases to the boiler room and use them as at least a part of the medium for burning the fuel on forced draft chain grates. Any escape into the boiler room of such gases as hydrogen-sulphide, sulphur dioxide and carbon monoxide makes operatating conditions a menace to health.

Dust also escapes from the front of a stoker, making operating conditions unsatisfactory.

It will, therefore, be seen that this feature not only allows the stoker chains to be kept cool at all times, but also allows the stoker to be successfully adapted to plants where waste gases are available, as outlined above. It also provides a clean boiler room so far as the stokers themselves are concerned.

STATEMENT BY THE PRAT-DANIEL CORPORATION, NEW YORK

The Prat-Daniel Corporation for a number of years has advocated the use of ball bearings with induced draft fans instead of water-cooled bearings. As shown in Fig. 35, a circular plate divided at the center so that it can be removed from the shaft is placed along the side of the induced draft fan portion of the Thermix Stack and located about 2 in. from the metal of the fan or stack itself. This radiation shield is approximately the same size as the fan wheel.

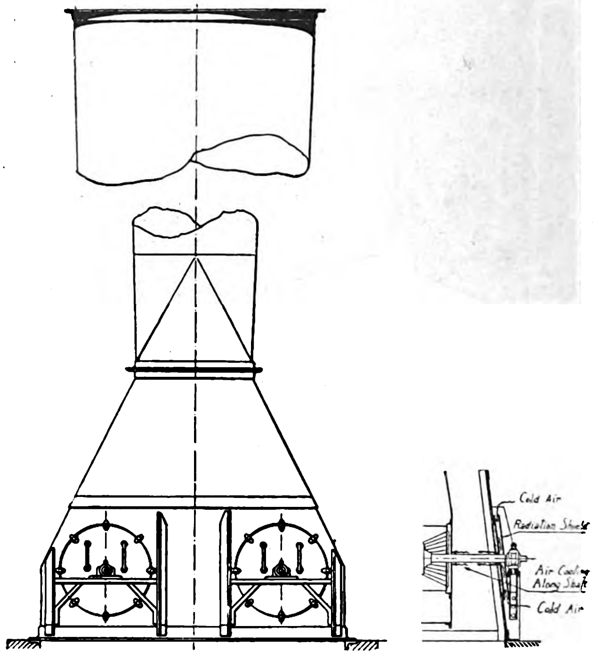

FIG. 35—THERMIX STACK AND INDUCED DRAFT FAN WITH BALL BEARINGS—PRAT DANIEL CORP.

An annular opening of about ¼ in. is made around the shaft at the point where it enters the fan casing or inlet box. Cold air is, therefore, constantly drawn to the point where the fan enters the casing, and thus the radiation shield is maintained at a low temperature. This properly protects the ball bearings from radiation from the stack casing.

It is also noted that this cold air leakage, which is not sufficient to materially affect the efficiency of the fan, carries the air directly along the shaft to the center of the fan, and thus maintains the shaft at a lower temperature than would otherwise be the case.

The Prat-Daniel Corporation has used this system in all of its installations, some of which handle gases up to 750 deg. fahr. No trouble is experienced from overheated ball bearings. This system is considered superior to water cooling due to the possibility of the water being shut off and the bearing becoming damaged in consequence.

STATEMENT BY THE RILEY STOKER CORPORATION, WORCESTER, MASS.

Riley Stokers

The demand for higher capacities and maximum efficiencies at high boiler ratings has continually increased during the past year, so that in practically every large stoker installation the stoker has been increased in length so that it takes up the entire furnace depth. This increase in the length of underfeed stokers necessitated many changes in their design. It was necessary to strengthen the main supporting members, which in the case of the Riley super-stoker are the reciprocating retort sides. This was accomplished with the Riley super-stoker by using a box construction in the side bars instead of merely extending one flange as used with the smaller Riley stokers. Fig. 36 shows this construction and gives some idea of the extreme ruggedness of the present side bars of the Riley air-zoned super-stoker and the method used to completely air-zone this stoker. A typical Riley air-zoned super-stoker is that installed at the Stamford Gas & Electric Company plant at Stamford, Conn; the length of this stoker is 19 ft., 2 in.

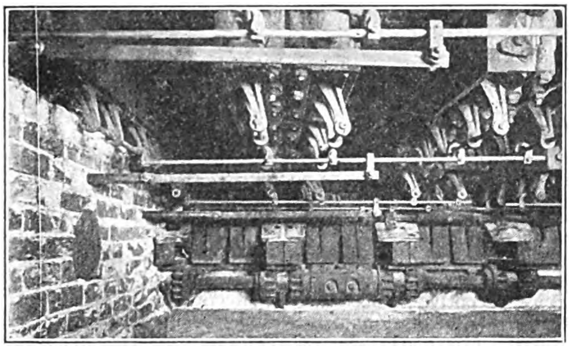

FIG. 36—STOKER CONSTRUCTION—RILEY STOKER CORP.

The high coal burning capacities of the modern underfeed stokers also demanded an increase in the size of the clinker-grinder pits. This was accomplished by the use of double roll clinker grinders and by increasing the depth of the pits to over 6 ft., as compared with previous designs having a depth of not quite 4 ft. The greater depth was obtained by increasing the size of the air admitting rocker grate. Fig. 37 shows the clinker grinder pit used on the large Riley super-stokers at the new unit of the Kearny Station of the Public Service Electric & Gas Company. A further refinement has been made to the operating mechanism of the clinker grinders. This mechanism is now so designed that each roll can be operated at a different speed, or, if desirable, one roll can remain stationary and the other roll can be operated at the speed desired. Details of this operating mechanism are shown in Fig. 38.

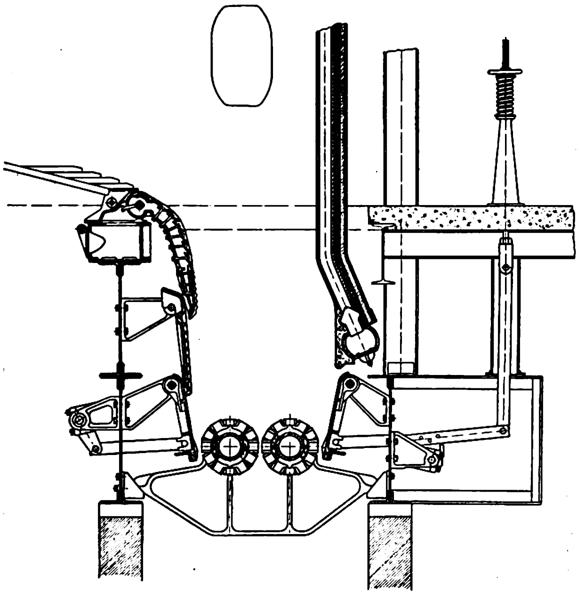

FIG. 37—CLINKER GRINDER PIT CONSTRUCTION—KEARNY STATION.

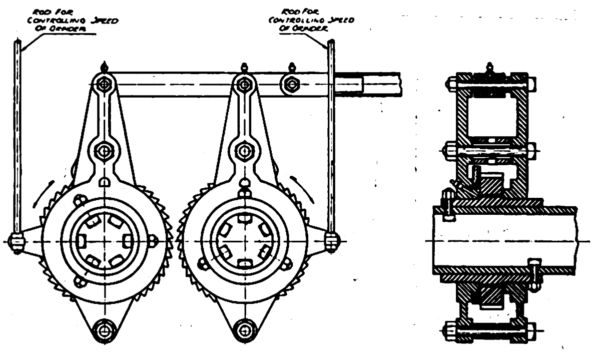
A new hydraulic drive for operating the clinker grinder of the Riley super-stoker has been developed and installed at the Kearny plant of the Public Service Electric & Gas Company. This drive consists of a hydraulic cylinder, which is operated by means of a special valve.

Because of the quantity of coal which must be fed to these large underfeed stokers, either the speed or size of the standard feeding mechanism must be increased materially. In order to retain maintenance at as low a figure as possible, the Riley Stoker Corporation has increased the size and stroke of the coal feeding mechanism, so that at the present time it has the greatest coal feeding capacity per stroke of any underfeed stoker. The use of the large plunger necessitated wider retorts, and on the face of things it would appear that this meant a decrease in the area of air admitting tuyeres. This disadvantage was overcome by increasing the size of the grate blocks immediately beyond the coal chutes, so that, with the Riley super-stoker, the ratio of air admitting grate area to retort area is very large.



ROD FOR CONTROLLING SPEED OF GRINDER
ROD FOR CONTROLLING SPEED OF GRINDER

FIG. 38—OPERATING MECHANISM CLINKER GRINDER ROLLS—RILEY STOKER CORP.

The use of highly preheated air has become quite standard. The limiting factor is stoker maintenance. One of the situations to be overcome when using highly preheated air was the large amount of expansion of the stoker, particularly with the largest size. It was not found necessary to make any changes in the general construction of the Riley stokers to take care of this expansion, because there is a free lengthwise expansion of 8 in. and free sidewise expansion of ¾ in. per retort. In the use of preheated air, therefore, the use of reciprocating retort sides proved most advantageous.

The use of preheated air in smaller plants is also increasing. A recent installation consisting of two 2500-sq. ft. return tubular boilers with Riley stokers, preheats air up to 510 deg. fahr. without an appreciable increase in maintenance.

The increase in the length of underfeed stokers has made necessary better air distribution and control throughout the length of the stoker. With the shorter stoker of a few years ago it was sufficient to have control over the air to the overfeed section and one control for the underfeed section, but that is not true with the stokers 20 ft. long. Present Riley super-stokers are completely air-zoned, the entire air admitting surface being under damper control. Each side bar is equipped with a variable number of small dampers depending upon the length of the stoker. Very often the number is as high as seven, so that with these long stokers there are seven different air compartments for each side bar. The air pressure in each of these zones can be controlled individually to meet any desired requirement. Fig. 36 shows these small air zones with the dampers and operating mechanism.

The design of the chute of the Riley super-stoker has

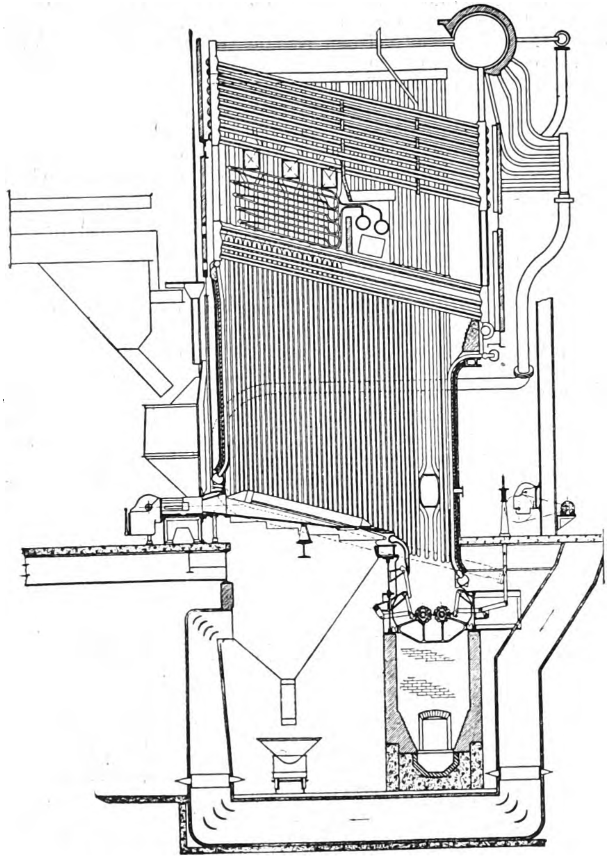


FIG. 39—BOILER UNIT—KEARNY STATION.

been changed so as to admit air at the front wall of the stoker. This air is under separate damper control, the operating handles being located at each side of the stoker at the front.

The effectiveness of the air-zoning feature of the Riley air-zoned super-stoker is indicated by the results being obtained at the Hollingsworth and Vose plant at West Groton, Mass. This is a small installation of a 5000-sq. ft. boiler without water walls, air preheaters or economizers, and in spite of this absence of auxiliaries, efficiencies of 83 per cent are being obtained.

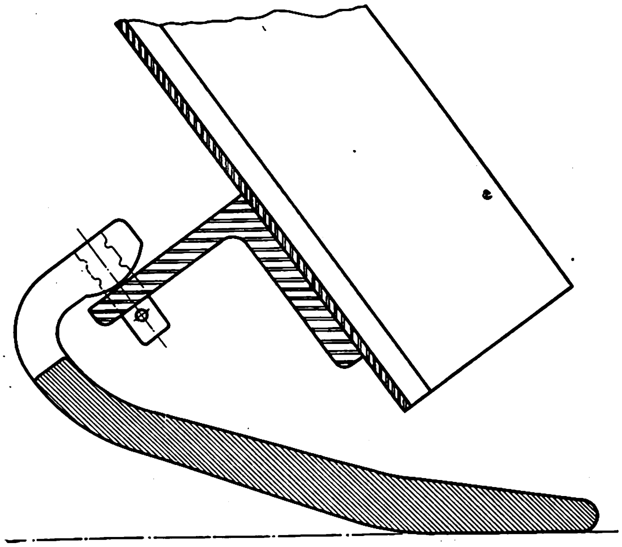

FIG. 40—CLIP LEVELING DEVICE—HARRINGTON TRAVELING GRATE STOKER.

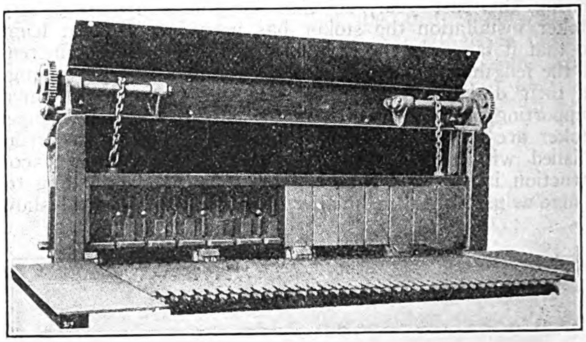

FIG. 41—GATE WITH REFRACTORY LINING—HARRINGTON STOKER.

New units of the Kearny Station of the Public Service Electric & Gas Company (Fig. 39) have been placed in service recently. This installation consists of 22,600-sq. ft. boilers with large double roll clinker-grinder stokers. High air preheat is used. An unusual feature is the water wall construction. The water walls completely cover the inside of the furnace, extending to the very top of the boiler instead of stopping at the boiler tube line. The additional heat recovery, because of this extension of the water wall tubes, more than pays for the additional expense of this construction.

Harrington Stokers

Refinements have been made to the Harrington traveling grate stoker. A clip leveling device has been developed, which forces the clips into mesh and at the same time eliminates any possibility of coal getting between the clip edges and preventing them from properly meshing. (See Fig. 40.) This improvement has materially reduced clip maintenance on many installations.

Improvement also has been made to the gate and gate lifting mechanism. The method of retaining the refractory lining in the gate is now designed so that the metal gate shoes are not subjected to the heat of the furnace. (See Fig. 41.) The gate lifting mechanism has been improved by using worms and gears, so that gates on the widest stokers can be easily raised or lowered, as shown in Fig. 42.

Unusual life has been given to the rear track of the Harrington stoker by using a renewable track of white iron, which is mounted on the base casting. When replacements are necessary they are easily made and at a low cost.

Gratifying results have been obtained with the Har-

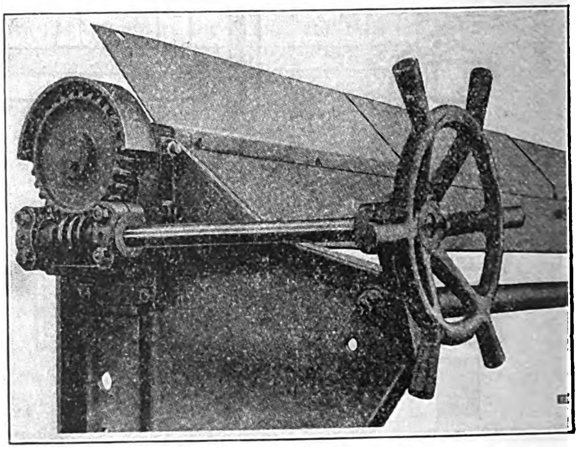

FIG. 42—GATE LIFTING MECHANISM—HARRINGTON STOKER.

rington stoker for burning the poor grade lignites of the Northwest. At the Kidder Station of the Otter Tail Power Company, Wahpeton, N. D., two 7500-sq. ft. boilers are each equipped with two 8 x 16-ft.-Harrington traveling grate stokers with a center refractory wall. Air preheaters are used. The installation has been operated at ratings as high as 300 per cent of boiler rating, and there is every indication that higher capacities could be obtained. Exceptional efficiencies are obtained with this lignite, which contains approximately 6500 B.t.u. per lb. and has a moisture content ranging as high as 40 per cent. With a good load factor the station can generate a kilowatt-hour on 3.5 lb. of this low B.t.u. high moisture coal.

A recent installation of Harrington stokers has been made for burning anthracite silt at the New York, Ontario and Western Railroad at Middletown, N. Y. This silt has a low B.t.u. content and a very high ash content. Results have been most satisfactory. Another installation for burning No. 4 buckwheat was completed at the Lehigh Wilkes-Barre Coal Co. at Wilkes-Barre, Pa. Operation with this fuel was very satisfactory.

An interesting installation of Harrington stokers is that at the Fitchburg Gas & Electric Company at Fitchburg, Mass. These stokers were installed primarily for burning an unmarketable grade of gas house coke breeze. This fuel when mixed with bituminous coal was tried on underfeed stokers but with unsatisfactory results, so that the disposal of it in this manner was abandoned. The fuel was handled very well with Harrington stokers. When this fuel was exhausted, the yard screenings from the different anthracite coal dealers in Fitchburg was used, and when this fuel supply was exhausted eastern bituminous coal was used. Mention of this installation is made because of the satisfactory use of three widely different fuels on the same stoker and with the same setting.

Jones Stokers

An unusual stoker drive has been developed for mechanically operating Jones stokers. This new drive is known as the Riflex mechanical drive because of its extreme flexibility. With this drive and the use of a constant speed motor, the coal feed to the stoker can be varied between the limits of 60 and 6000 lb. of coal per hr. Coal can be fired at practically any rate between these two limits. The drive consists of a single spur gear reduction, and the extreme flexibility is obtained by using an intermittent stroke of the plunger. The number of strokes per hour depends upon an unique timing mechanism, which is illustrated in Fig. 43.

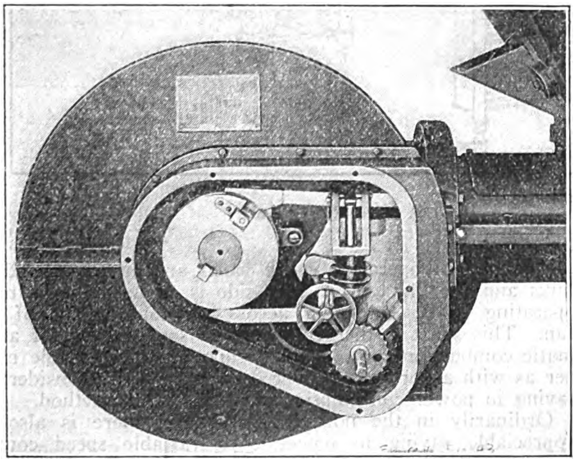

FIG. 43—TIMING MECHANISM—JONES STOKER.

Based on experience with the original Jones stoker unit, a new unit has been developed. The fan and motor have been removed from under the stoker ram case, where they were subjected to the heat of the furnace and where they operated in a great deal of dirt and grit. They are now located in front of the stoker drive, where they are accessible and away from the furnace. This still gives a compact unit without the disadvantage of the original unit. This unit, with which the Riflex drive is used, can be tied into automatic control in so far as wind box pressures and coal feed is concerned. This is accomplished by using a regulating valve which varies the rate of coal feed and controls the damper on the forced draft fan.

Riley-La Mont Water Wall

As an alternative to natural boiler circulation and large diameter tubes the Riley-La Mont water wall (Fig. 44) is available. It is based upon the use of forced circulation and constructed of long diameter flexible tubes in conjunction with relatively small headers which insure positive and proper distribution of the forced circulation.

In the Riley-La Mont water wall positive circulation is maintained in a single direction by means of a centrifugal pump of proper characteristics and by distributing orifices, which meter the proper quantity of water to each individual tube. Water enters the circulating pump by gravity from a drum of the boiler and its pressure is increased by the pump from 15 to 40 lb., depending upon the rate of heat absorption of the water walls, diameter and length of tubes, number of bends, etc. This water enters a header which is supplied with distributing orifices that meter the proper quantities of water supplied to each tube.

The capacity of these orifices is such that the quantity of water forced into each tube is several times the quantity of water which will be evaporated under the conditions of maximum heat absorption. This quantity of water, however, is insufficient to fill the tube.

As heat is absorbed in the tube, part of the water is turned into steam, which compared to the quantity of water is very great in volume. This steam produced cannot find its way out of the orifice due to the pressure drop of water across the orifice caused by the mechanical pump circulation. The orifice end being closed to steam travel gives a positive insurance against steam locking in the tube. The steam produced therefore must leave the other end of the tube, entering the header which is connected into the steam space of the boiler.

The tubes are long, compared to their cross sectional area, so that the steam produced generates exceedingly high velocities in the tubes. By selecting the proper diameter of tube relative to its length and duty, this velocity can be kept between approximately 1000 to 4000 ft. per min. or more, which is many times as fast as the velocity of water and steam in a natural circulation type of water wall. The steam from the header moving at great velocity carries with it the excess water which entered through the orifices. This amounts to approximately 80 per cent by weight, but is only about 1 or 2 per cent by volume.

It may be seen that with such positive circulation steam binding under these conditions is impossible, and the precipitates formed will be swept from the tube surface by the high velocity of water and steam provided the water has been softened by chemicals to any reasonable degree. The reverse is also true.

If through careless water treatment a scale is formed the use of an increased quantity of chemicals will soften the surface of the scale which the high velocity of water and steam will gradually wear away as each layer of softened surface scale is exposed.

Further, with forced circulation, the tubes may be installed vertically, horizontally or inclined in any direction with the flow either up or down and the tubes can also be bent at any angle to avoid structural obstacles and furnace openings. Due to high velocities in the tubes, the headers and connecting pipes to the drums can be very small in comparison with natural circulation types of water walls, to convey a given quantity of steam carrying its small amount of moisture.

FIG. 44—CONSTRUCTION OF RILEY-LA MONT WATER WALL SYSTEM.

STATEMENT BY THE B. F. STURTEVANT COMPANY, HYDE PARK, BOSTON, MASS.

Induced Draft

In the 1927-28 Report of the Subcommittee on Stokers and Furnaces, the Sturtevant Turbovane I.D. fan for induced draft was announced. There are two main features, not found on any other type of induced draft fan. The first is the elimination of the uncertainty of inlet box loss by supplying inlet boxes as an integral part of the fan, the fan characteristics having been determined with these boxes attached to the fan. These boxes are of spiral shape and are provided with spiral vanes which guide the gas into the wheel evenly from all sides, thus eliminating the indeterminate effect of the uneven inlet flow resulting from the older type of inlet box.

The second, and almost as important feature, is the method of volume and pressure control. The spiral shaped vanes in the inlet boxes are made to pivot on short shafts at each side of the inlet boxes, the vanes overlapping each other when entirely closed. The fan is driven by a constant speed squirrel cage motor and the pressure and volume controlled by opening or closing the vanes. Fig. 45 shows the method of operation. The vanes are interconnected by links and the linkage on each side is connected to a main operating shaft, extending across the top or side of the fan. This shaft is then connected to some system of automatic combustion control which functions in the same manner as with an ordinary boiler damper but with considerable saving in power consumption over this latter method.

Ordinarily in the normal load range, there is also an appreciable saving in power over variable speed control in addition to the saving in motor investment.

Forced Draft

For forced draft, the volume is controlled by V-shaped vanes placed radially in the cone inlet. These vanes are operated by bevel gears and a linkage similar to that used on the induced draft fan. This is shown in Fig. 46.

STATEMENT BY THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY

Probably the most outstanding development in coal burning equipment in recent years is the application of an undulating link-grate overfeed section to long multiple retort underfeed stokers. Fig. 47 illustrates this arrangement. In combination with the usual underfeed retorts, it produces a stoker which has the simple and effective combustion principles of the underfeed stoker and the positive fuel and refuse conveying ability of an undulating link-grate system.

Fig. 48 shows the application of a 15-retort stoker of this type under a 23,800 sq. ft. B. & W. boiler at the Hudson Avenue Station of the Brooklyn Edison Company. Four of these units are in service. Fig. 49 is a preliminary layout for the three 31,800 sq. ft. boilers for the new Reed Station of the Duquesne Light Company on Brunots Island, Pittsburgh.

The principle of this design is that a flat undulating grate surface of large area extending across the entire width of the furnace moves as a unit at the rear of the stoker. It receives fuel and refuse discharged from the lower ends of the retorts of the underfeed stoker and effectively completes the combustion of this fuel and discharges the refuse into the clinker-grinder pit. This overfeed grate surface is made of a sufficient size so that large quantities of coal may be burned on it, thereby permitting a large amount of coal to be discharged from the retorts. In fact, so much coal is discharged that the ash, which normally collects on the lower tuyeres of the underfeed stoker, is almost completely wiped away by the moving coal. The fire on the underfeed section is, at all times, free from undesirable ash and clinker accumulations.

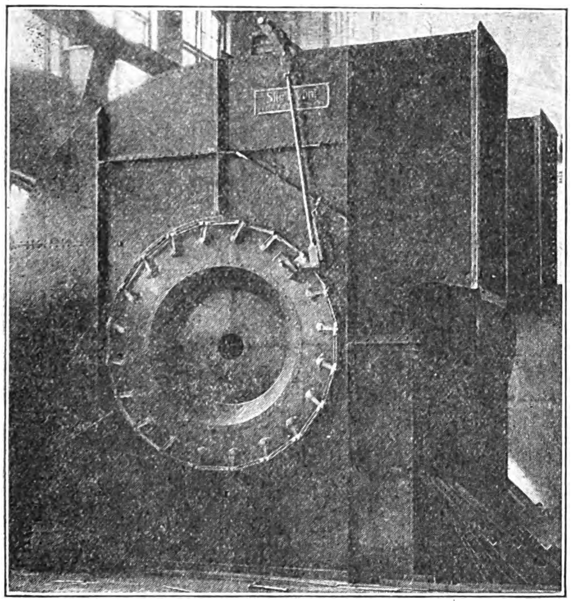

FIG. 45—VANE CONTROL INDUCED DRAFT FAN—B. F. STURTEVANT CO.

This flat and continuously moving grate surface carries the fuel and refuse away from the underfeed section uniformly, regardless of the character of the fuel or its clinkering tendencies. Therefore, a constant minimum resistance is present at the lower end of the retorts and the retorts are enabled to maintain proper fuel distribution with very little attention or adjustment by the operator.

The fuel is burned on the overfeed section in approximately the same combustion cycle as on the underfeed section. The streams of fresh fuel pass from the retorts onto the grate, while streams of ash and actively burning coke pass from the tuyere rows on to the grate. The motion of the grate is such that as the fresh fuel from the retorts moves along, it is spread into the burning lanes from the tuyeres until a homogeneous body of ignited fuel results. The lower end of the overfeed grate completes the combustion of the mixture of coal and ash and discharges the refuse positively and uniformly into the clinker-grinder pit.

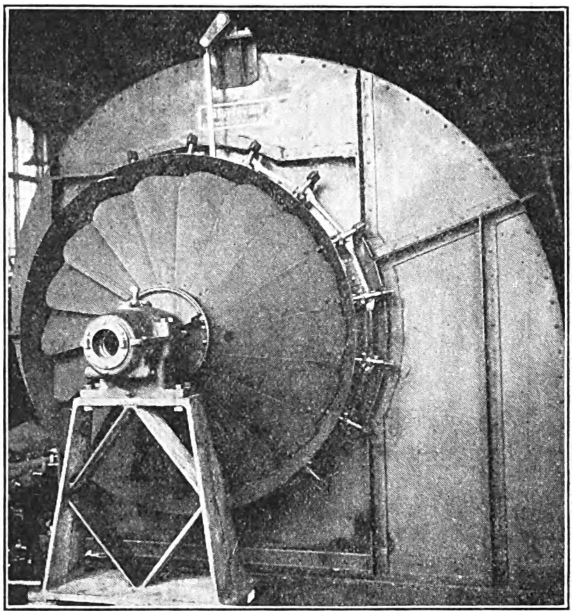

FIG. 46—VANE CONTROL FORCED DRAFT FAN—B. F. STURTEVANT CO.

The motion imparted to the overfeed grate surface combining positive conveying action and breaking motion, prevents the formation of large clinkers. The refuse is well broken and uniformly sized and is ground very easily and uniformly by the clinker grinder.

The motion of the undulating link-grate overfeed element is controlled separately from that of the stoker feeding rams. Therefore, the regulation of the ash discharge from the stoker is accomplished without disturbing the distribution of fuel in the retorts and over the tuyeres. Separation of the two control functions makes the stoker adaptable to handling all grades of fuel with a minimum of attention and adjustment. Adjustments to compensate for changes in the ash content or other characteristics of the fuel can be made whenever their necessity becomes apparent, without interfering in any way with the rate of feeding of the fuel.

A brief description of the link grate will illustrate its action.

Referring to Fig. 47, it will be seen that the grate consists of a series of grate supporting frames hinged together to form a chain-like series as shown by A-B-C-D-E. The upper frame A as pivoted to the lower end of the underfeed section, or retort, at P.

The grate surface proper consists of grate bars fastened in the frames, and the grate bars assemble into a flat, smooth grate surface. The frames are each 21 in. wide,

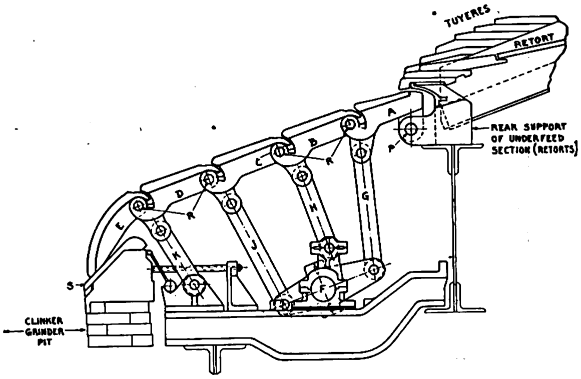

FIG. 47—UNDULATING LINK GRATE OVERFEED SECTION—WESTINGHOUSE UNDERFEED STOKER.

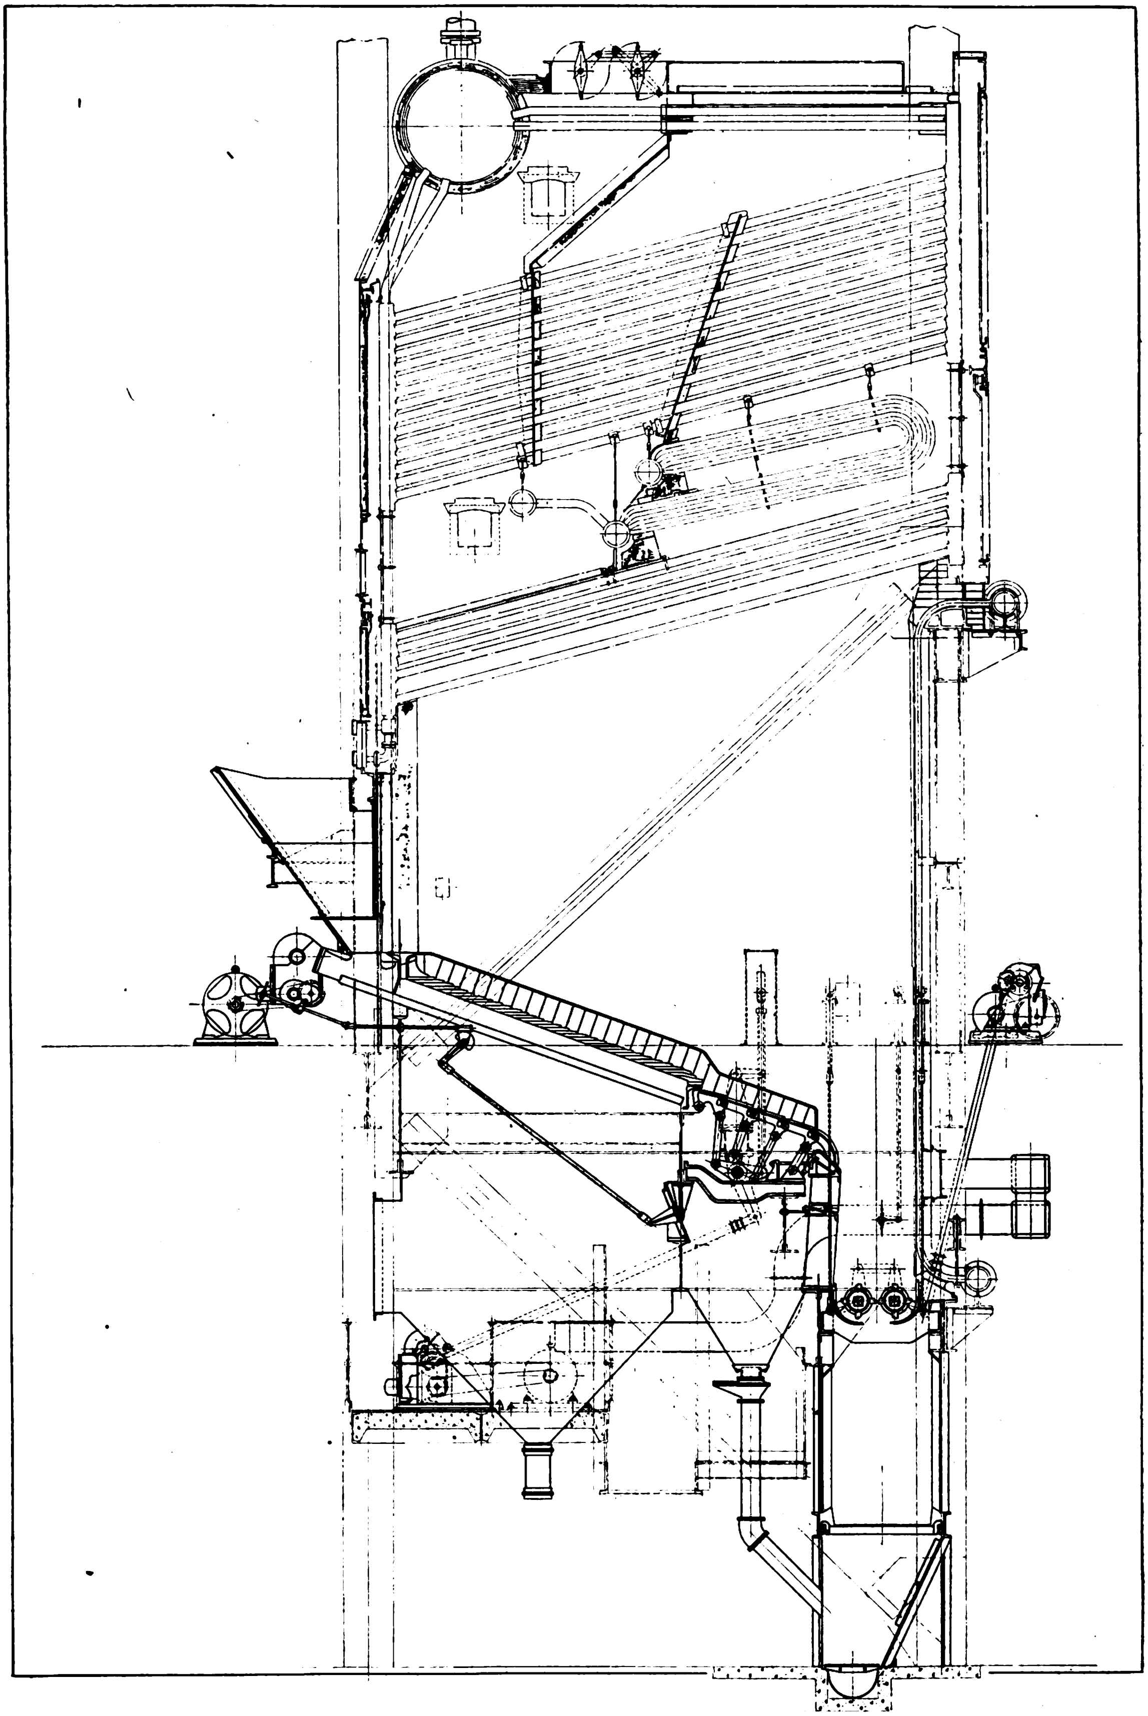

FIG. 48—WESTINGHOUSE UNDERFEED STOKER WITH UNDULATING LINK GRATES.

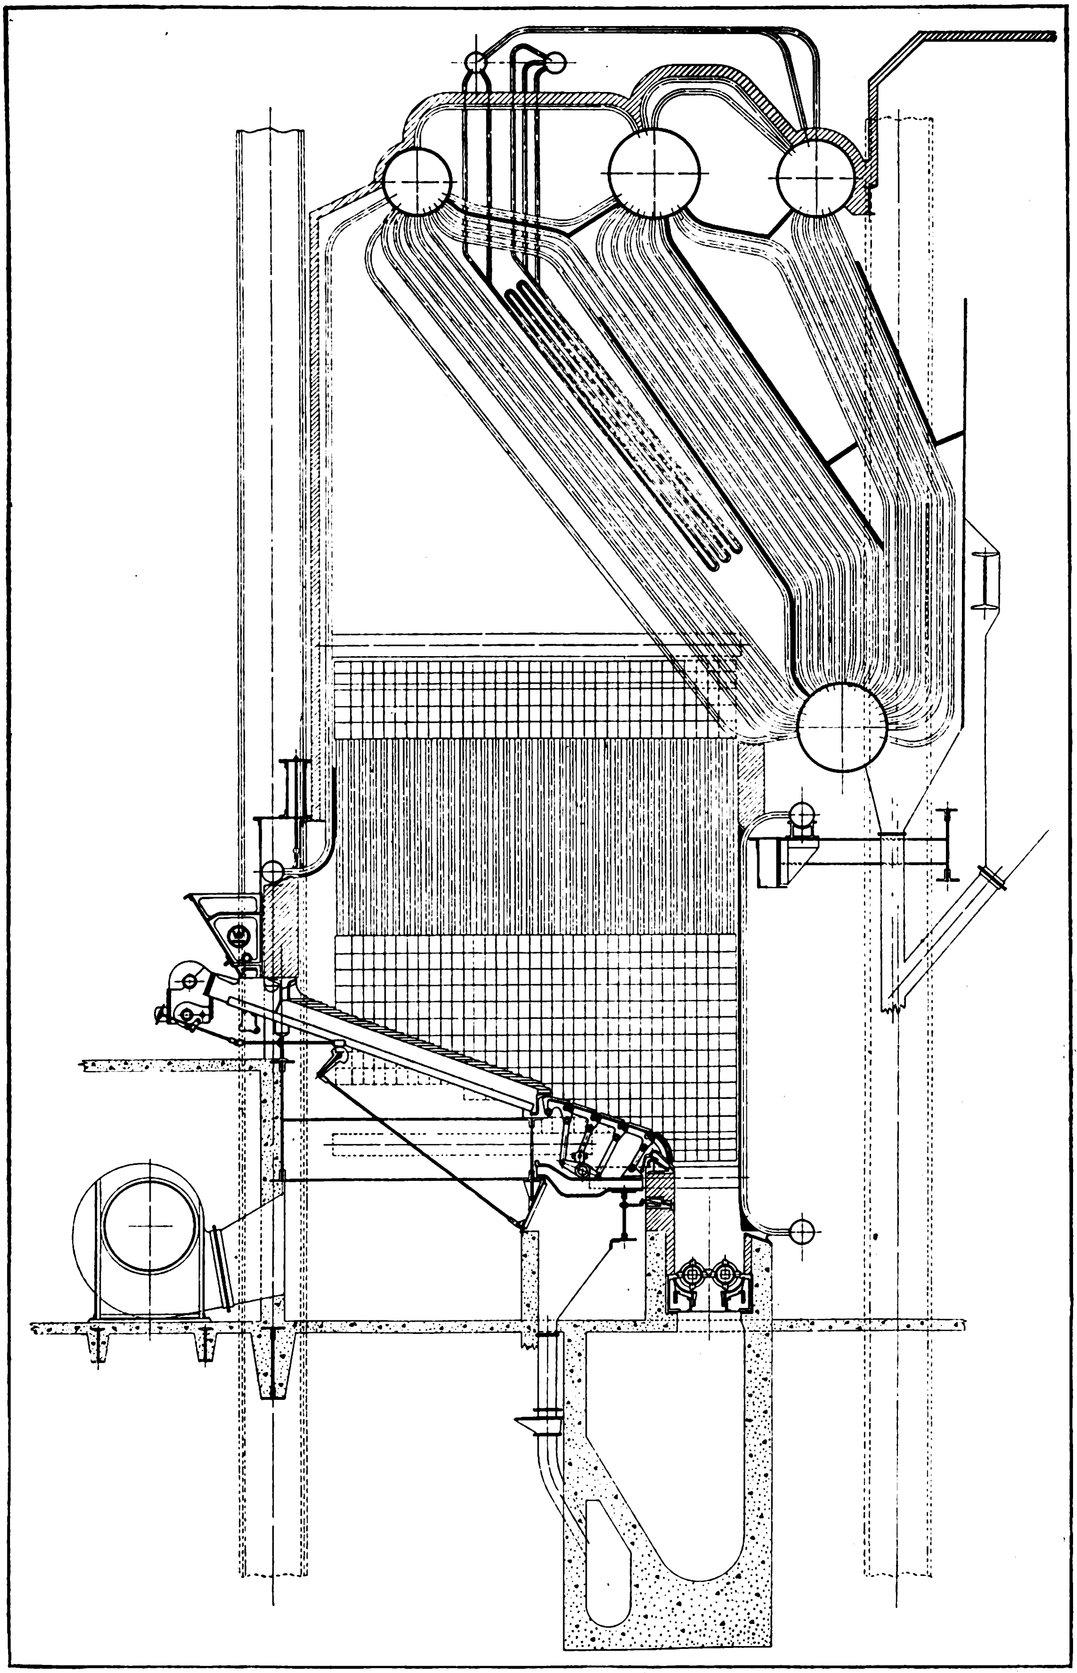

FIG. 49—PRELIMINARY LAYOUT FOR THREE NEW BOILERS—REED STATION—DUQUESNE LIGHT CO.

corresponding to the width between centerlines of tuyere rows. Hence, the grate surface is composed of 21-in. sections. In each frame there is a key grate which is retained by a removable pin. Removing the pin and the key grate allow the remaining grates in the same frame to be lifted out when necessary for renewals.

A drive shaft, F, imparts motion to a rocker bar which, through arms G and J, impart rocking motion to the ends of frames A and C. This sets the entire grate system in undulating motion.

Links H and K merely act as free-moving supports for the other joints of the system. A stationary grate, S, supports the sliding lower end of frame E.

The rest or zero position is shown in Fig. 47. The solid lines, Fig. 50, indicate the positions of the frames when frame A is in its highest position. The dotted lines indicate positions when frame A is in its lowest position.

It will be noted that, due to pivot P being below the line of centers of the hinge pins, oscillation of frame A causes this frame to have a reciprocatory motion, which in turn gives the entire grate system a similar motion. This reciprocatory motion gives the link grate its conveying or fuel propelling effect.

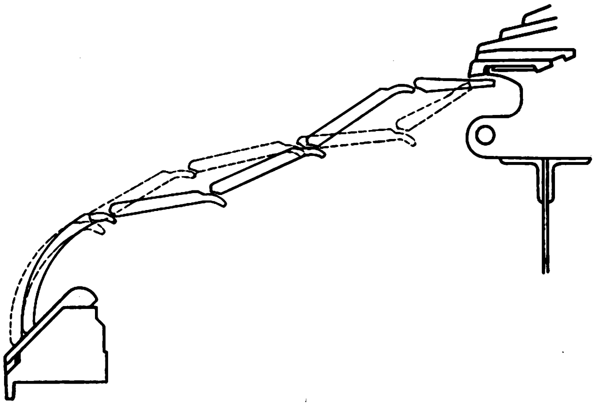

FIG. 50—DIAGRAM OF UNDULATING GRATE SECTION—WESTINGHOUSE UNDERFEED STOKER.

The rocker shaft F is operated by a gear box and crank mechanism. The application of the gear box and operating mechanism is made to conform to the requirements of the individual installation. The shaft F may be either extended through the boiler side wall and operated by a mechanism placed in the boiler aisles, or it may terminate at the side walls and be operated at or near its middle by a driving rod extended through the front of the stoker and connected to a gear box located below the stoker gear boxes.

The gear box is usually driven by a silent chain from the stoker speedshaft, or from a jackshaft driven by the stoker driving motor. In some cases a separate motor may drive the link-grate, the controller of this motor being mechanically connected with the controller of the stoker driving motor, to synchronize the speed control of the two drives.

The connection between the gear box and driving shaft F contains a lost motion device to enable the operator to vary the motion of the grates as desired. By means of a simple device, the motion of the grates is controlled in six increments from zero to maximum. A shearing pin is provided to protect the mechanism from overloads, such as would be caused by an excessive accumulation of refuse in the clinker-grinder pit due to operating negligence.

This structure produces the following results:

1. A flat grate surface that exposes a minimum of surface to the fire and is thoroughly cooled by air passing between and around narrow grate bars.
2. A grate surface which positively conveys the fuel and refuse toward the rear of the stoker.
3. A grate motion which agitates the fuel sufficiently to always keep the fuel supporting surface uniformly covered.

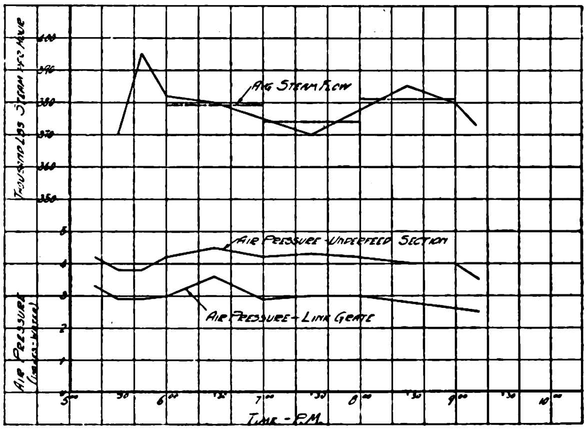

FIG. 51—CURVES FOR WESTINGHOUSE STOKER—HUDSON AVE. STATION.

4. A grate motion which, in combination with the positive ash conveying properties of the grate, prevents the formation of large clinkers, and discharges into the clinker-grinder pit the refuse which is thoroughly burned out and is of a size easily and uniformly handled by the clinker grinder.
5. An ash ejecting mechanism, attached to the lower end of the underfeed section, which is positive in action, and which is regulated without disturbance of the fuel feeding and distributing mechanism. Fig. 51 shows the relatively low air pressures required at high capacities on the boilers at Hudson Avenue. These curves were made from data obtained during regular operation. The load recorded was the highest available during a peak period and does not represent the ultimate capacity of the units, as was clearly indicated by the ease with which the fuel bed was handled and its condition. No official tests have yet been run, but observations indicate an average overall efficiency of 85 per cent or more. There are economizers, but no preheated air. Maintenance is amazingly low.

Clinker-Grinder Pit

The Hudson Avenue stoker is equipped with a clinker-grinder pit embodying radically new features of design. This type of grinder pit has also been applied to later installations, of both conventional underfeed stokers and combined underfeed and link-grate stokers.

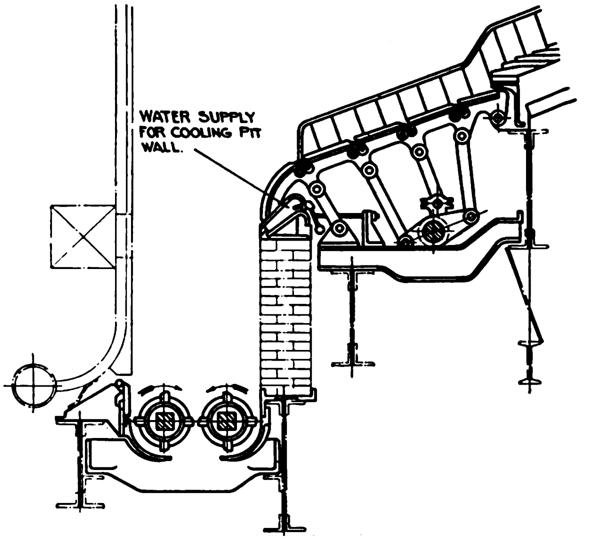

FIG. 52—FRONT PIT WALL—HUDSON AVE. STATION.

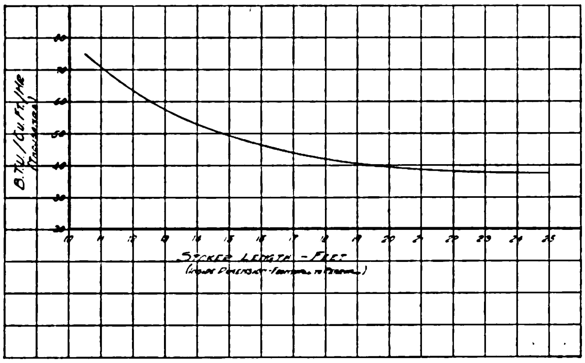

FIG. 53—HEAT LIBERATION CURVE—WESTINGHOUSE ELECTRIC & MFG. CO.

The design employs a front pit wall of hard-burned firebrick, Fig. 52. The base of the wall is supported by the casting to which the front clinker-grinder shield is attached. The upper edge of the wall is capped by a casting which supports the lower end of the link grate, or the agitator of the usual type underfeed stoker. Water is discharged from the bottom of this casting and trickles downward over the face of the wall between the brickwork and the refuse. The effect is to create a film of water over the face of the wall, which will not allow slag to stick to the refractory material. Water is not sprayed into the refuse.

When it is desirable, air can be discharged through the wall. To do this, hollow castings are built into the wall to form air passages. These castings expose a minimum of surface to the heat of the refuse.

It is preferable that the rear wall of the grinder pit be some form of water wall. If the economics of the installation do not permit the use of a water wall, the rear wall of the pit may be built similar to the front wall.

This construction eliminates, as far as possible, the use of cast iron parts in the clinker-grinder pit, and by thus reducing the number of parts subject to the destructive action of heat insures reliability and continuity of service.

Setting Heights and Furnace Volumes

There is a tendency toward setting boilers unnecessarily high when used with short stokers, and too low when used with long stokers. The setting height of a boiler and consequently the furnace volume are influenced by the character of the fuel to be burned, and the length of the stokers. Fig. 53 shows what this company has determined as a general basis upon which to figure the maximum heat liberation per cubic foot of furnace volume for maximum combustion efficiencies. This being a general basis, it must be modified for the particular characteristics of fuel under consideration. Having determined the total coal to be burned and the heat release per cubic foot, the effective furnace volume is established. In determining the setting height, due consideration must be given to the shape of the furnace and the relation of the natural flow of gas from the fuel bed to the heating surface of the boiler as affecting the effective furnace volume.

Water Walls

Experience teaches that water walls have several advantages. They do prevent clinker adhesions at and just above the line of the stoker. They do have some effect upon reducing exit gas temperature, which is synonymous to increasing efficiencies, but to exactly what extent this is accomplished is problematical. The first place to consider the placing of water walls on a multiple retort stoker is at the rear above the dump grate or in the rear wall of the grinder pit. Next would come the side walls. We have seen no advantage in front water walls. Water walls considerably affect furnace conditions. The right amount of water wall is highly desirable, but if the amount of bare iron surface becomes too great with respect to the furnace volume, the furnace temperature may be too low, ignition will be slow, particularly on single retort stokers, and combustion reactions may be slowed down enough to lower the efficiency.

Preheated Air

Preheated air does not increase capacity. The same capacity may be obtained with less coal. Preheated air within the range used for boilers has no detrimental effect upon the stoker proper, but temperatures much above 350 deg. create conditions in the fuel bed which may make it difficult to handle. Many of the earlier difficulties have been overcome by changes in design.

Most installations suffer more difficulties with corrosion, warping and fouling of the preheaters, and with expansion troubles and leakage in the air ducts than are encountered with the stoker proper. All of these factors can be overcome by proper layout and design. The experience gained in the existing preheated air installations is now a valuable guide for future layouts.

Single Retort Stokers

Experience with single retort stokers demonstrates that satisfactory coal distribution becomes more difficult to obtain as the length of the retort increases. Fuel distribution throughout the length of the stoker is the combined func-

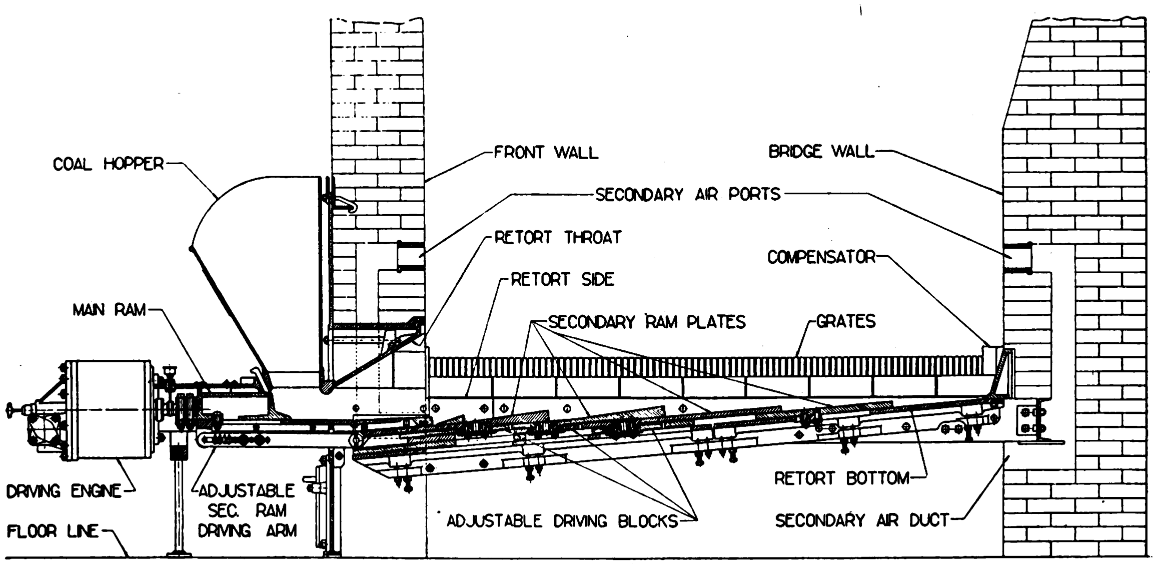

FIG. 54—DESIGN OF SINGLE RETORT STOKER—WESTINGHOUSE ELECTRIC & MFG CO.

tion of the retort and the secondary ram. Experiments were conducted to produce a design of these elements that is sufficiently flexible to give satisfactory distribution for different grades of coal and varying furnace conditions. The design as finally adopted is shown in Fig. 54. The retort is relatively deep at the throat, with a sharp upward slope to the bridgewall. This shape of retort enables the secondary ram to push the coal upward and over the grates at a uniform rate. The retort being shallow at the rear end, the secondary ram is rendered most effective in ejecting from the retort any clinkers or hard coke formations which may accumulate during a long banked period.

Adjustments to obtain correct fuel distribution for the available coal are made by varying the lost motion in the elements of the secondary ram. This adjustment is made from the windbox and is of a more or less permanent character.

The secondary ram having a fuel moving capacity in excess of that of the main coal feeding ram, permits the use of a lost-motion device between the main and secondary rams to make these desired adjustments.

The pushing faces of the secondary ram plates are self-cleaning to prevent fouling with wet coal dust which would result in loss of effectiveness.

CONDENSING EQUIPMENT

Summary

Owing to the lack of sufficient data and to variations in conditions under which condensers operate, it is very difficult to make an accurate comparison of the performance of the several types of surface condensers.

A study of the data received by this committee. after being corrected to a common basis of water velocity and inlet water temperature, indicates that the performance of single-pass condensers is somewhat better than that of the two-pass type. Performance of vertical condensers is appreciably better than horizontal condensers with the same number of passes.

Tables included give design and performance data for fifteen two-pass and eleven single-pass condensers. The variation of average heat transfer rates with inlet water temperatures is also shown.

Excessive condenser leakage resulting from tube vibration has been experienced in some cases. This has been most effectively remedied by the installation of additional tube support sheets and by the use of thicker tubes.

Two companies report satisfactory operation with condensers having the tubes rolled into the tube sheet at both ends.

STUDY OF PERFORMANCE RECORDS OF SINGLE-PASS AND TWO-PASS CONDENSERS

The work of the Subcommittee during the past year has been almost entirely confined to a study of the relative performance of single and two-pass condensers. It has been based upon data supplied by members of the Prime Movers Committee, approximately complete data having been obtained for 15 two-pass and 11 single-pass installations. The data for these installations have been tabulated and are shown in Tables I and II.

Statements received from companies supplying data are included in the latter part of this report, together with curves showing the performance of each condenser.

It is very difficult to appraise the value of any given type from the performance of such a limited number of condensers which is affected not only by the amount of air leakage, but to a very great extent by the fouling characteristics of the circulating water and the frequency with which the tubes are cleaned.

The following comparisons are based entirely upon the data given in Tables I and II and have general application only to the extent that the installations reported are representative of the single and two-pass designs. The limitations of this study should be borne in mind when considering these comparisons.

Relation of the Actual to the Expected Coefficient of Heat Transfer

The average ratio of the actual to the expected heat transfer coefficient was found to be 0.835 for all two-pass and 0.808 for single-pass installations. The minimum and maximum ratios for individual single-pass condensers were 0.66 and 0.86 respectively. For individual two-pass condensers, the minimum ratio was 0.63 and the maximum 1.28. Two two-pass condensers gave an average ratio of actual to expected heat transfer in excess of unity. In some cases the expected values were based upon manufacturers' guarantees and in others upon test data obtained when the tubes were clean. Since in nearly all cases the air leakage was reasonably low, the performance with clean tubes corresponded closely with the manufacturers' guarantees. The difference between actual and expected heat transfer results mainly from fouling of the condenser tubes.

Comparison of Heat Transfer in Single-Pass and Two-Pass Condensers

Tables III and IV show performance results obtained with inlet circulating water temperature of 35, 55 and 70 deg. fahr. These values were taken from the curves plotted for individual condensers. It will be noted that data for the 35 deg. circulating water temperature were not available in all cases. In addition to the actual heat transfer coefficient and water velocity, the heat transfer coefficient corrected to a water velocity of 6 ft. per sec. is shown. The average water velocity was 6.3 ft. per sec. for two-pass condensers and 6.25 ft. per sec. for single-pass condensers.

The correction for circulating water velocity was based upon test data obtained by G. A. Orrok (A. S. M. E. Trans., 1910, Vol. 32, p. 1773). The results obtained in Mr. Orrok's tests were corrected by E. E. Wilson (A. S. M. E. Trans., 1915, Vol. 37, p. 47) to an arbitrary mean water temperature of 60 deg. fahr. and the reciprocal of the corrected coefficients of heat transfer were plotted by him against the reciprocal of the water velocity in the tubes. The test points plotted in this manner fell very close to a straight line, indicating that there was an approximate straight line relationship between the resistance to heat transfer and the reciprocal of the water velocity. The corrections made in this report for variation in water velocity were determined from the slope of this line. A line plotted from the reciprocal values of heat transfer coefficients and water velocities for mean water temperatures of other than 60 deg. fahr. will have a different slope than the 60-deg. line. The relation

between the reciprocal values referred to above were therefore determined for other mean water temperatures by varying the 60-deg. value in accordance with Poisenelles' value for the ratio of viscosity to density of water, with temperature. From the preceding, corrections were made as follows to the reciprocal of the coefficient of heat transfer per unit of difference between the actual and arbitrary value of the reciprocal of the water velocity which is 0.1667.

35 deg. inlet temperature........	0.0053
55 deg. inlet temperature........	0.00385
70 deg. inlet temperature........	0.00320

The average heat transfer coefficients corrected to 6 ft. per second water velocity for condensers reported in Tables III and IV were as follows:

For 8 Single-Pass and 10 Two-Pass Condensers

Inlet circulating water temperature	35 deg.	55 deg.	70 deg.
Average corrected heat transfer for single - pass condensers (B.t.u. per sq. ft. per hr. per deg.)	240	331	393
Average corrected heat transfer for two-pass condensers (B.t.u. per sq. ft. per hr. per deg.).....	200	276	356

For 11 Single-Pass and 15 Two-Pass Condensers

Inlet circulating water temperature	35 deg.	55 deg.	70 deg.
Average corrected heat transfer for single - pass condensers (B.t.u. per sq. ft. per hr. per deg.)	240	352	409
Average corrected heat transfer for two-pass condensers (B.t.u. per sq. ft. per hr. per deg.).....	200	281	351

These average values of heat transfer coefficient are higher for the single-pass condensers than for two-pass condensers as shown below:

Inlet water temperature deg. fahr.	Per cent greater heat transfer—single over two pass
35	20
55	25
70	17

This difference may be partly due to the use of smaller tube sizes in the single-pass designs. Of the eleven single-pass condensers reported, three were equipped with ¾-in. tubes, four with ⅞-in. tubes, two with 1-in. tubes and two with tubes of three different sizes (¾, ⅞ and 1 in.). The two single-pass condensers having tubes 1 in. in diameter gave a heat transfer coefficient approximately 12 per cent lower than the average of all of the single-pass installations.

Only one two-pass condenser was equipped with tubes smaller than 1 in. in diameter. Although this unit gave a performance slightly better than the average of all two-pass installations, the performance was 8 per cent lower than that of a condenser of the same size and manufacture installed in the same station but equipped with 1-in. tubes.

Fig. 1 shows the arithmetical mean temperature difference obtained with 70 deg. inlet water temperature corrected to 6 ft. per sec. water velocity, plotted against the rate of heat transfer. It will be noted that if the four single-pass condensers which were operated at the highest rates of heat transfer were excluded, the average performance of the single-pass condensers would be approximately the same as that of the two-pass installations.

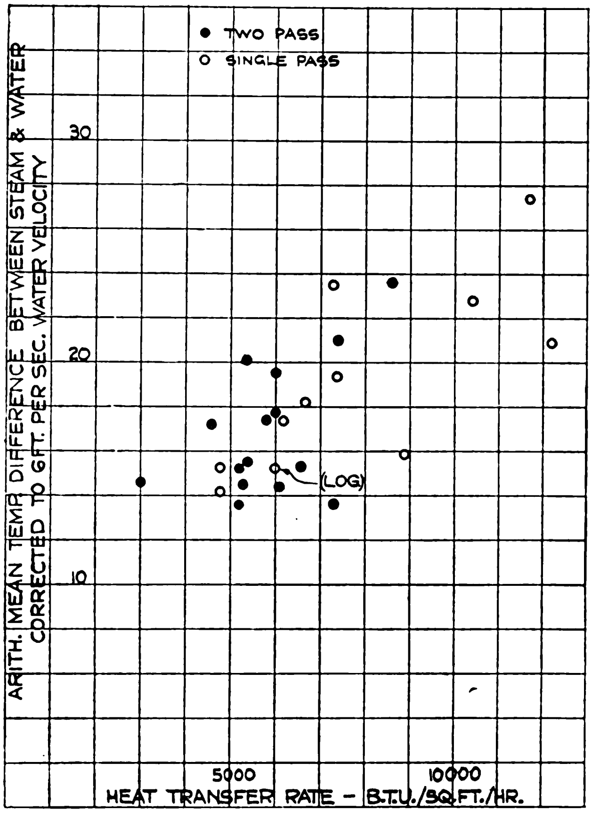

FIG. 1—Values of Arithmetic Mean Temperature Difference Obtained with 70 Deg. Fahr. Inlet Water Temperature.

Vertical Condensers

Three of the condensers for which data have been received are of the vertical two-pass type and were made by the same manufacturer. Two are installed in the same station. The average ratio of actual to expected heat transfer for these condensers is 1.10 compared to the average of 0.835 for all two-pass condensers. Comparison of the average heat transfer coefficients corrected to 6 ft. velocity of the circulating water of the three vertical condensers at three inlet water temperatures of 35, 55 and 70 deg. fahr. with the coefficients for all two-pass condensers at the same inlet water temperatures shows better heat transfer of the vertical type as follows:

Inlet water temp.	Per cent greater heat transfer
35 deg. fahr.	19
55 deg. fahr.	10
70 deg. fahr.	26

The heat transfer coefficients of these three vertical condensers plotted against the inlet water temperature gives a curve that is concave upward whereas the other condensers give curves that are either straight or are concave downward.

Circulating Water Quantities

As is to be expected, a greater quantity of circulating water is used with single-pass condensers than with two-pass. The quantity of water per thousand B.t.u. of average heat transfer obtained with the circulating water pumps operating at full capacity is 109 lb. for two-pass and 149 lb. for single-pass condensers. The average head across the circulating water pumps when operating at full capacity is 20.5 ft. for two-pass condensers and 18.5 ft. for single-pass.

The efficiency of the circulating water pumps has been determined from power consumption and water quantity data obtained with the pumps operating at full capacity. The average efficiency of the pumps used with two-pass condensers is 64 per cent as compared with 71 per cent obtained for the pumps operated with single-pass units. Owing to the difficulty of member companies accurately determining the values upon which the efficiency calculations are based, the pump efficiencies above are no doubt considerably in error.

Effect of Circulating Water Velocity on Heat Transfer

The correction made for the effect of water velocity on the heat transfer coefficient as shown in Tables III and IV was based upon tests made with clean tubes and hence no allowance is made for any possible effect of water velocity on the cleanliness of the tube. In order to determine whether the water velocity has an appreciable influence on the fouling of the condenser tubes, the values of heat transfer coefficient corrected to 6 ft. per sec. water velocity have been plotted against actual water velocity. This relation is shown for 55 deg. inlet water in Fig. 2 and for 70 deg. inlet water temperature in Fig. 3. It will be seen that while the very highest values of heat transfer were obtained with the higher water velocities, there is no definite relation between the water velocity and the heat transfer.

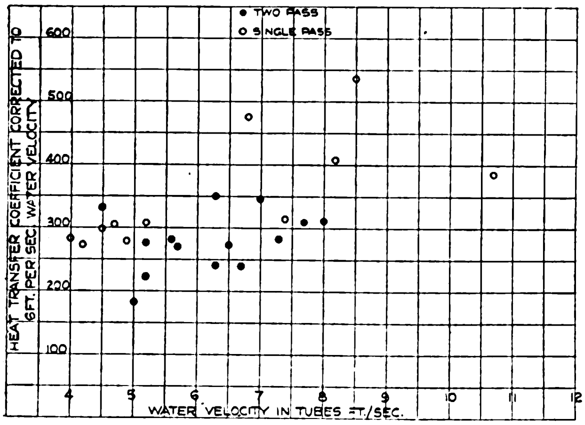

FIG. 2—RELATION OF WATER VELOCITY AND CORRECTED HEAT TRANSFER COEFFICENTS WITH 55 DEG. FAHR. INLET WATER TEMPERATURE.

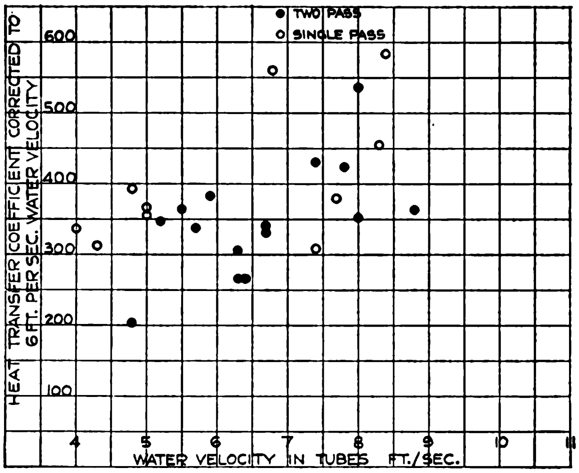

FIG. 3—RELATION OF WATER VELOCITY AND CORRECTED HEAT TRANSFER COEFFICIENTS WITH 70 DEG. FAHR. INLET WATER TEMPERATURE.

The relation between the average water velocity and the ratio of actual to expected heat transfer is shown in Fig. 4. The ratio of actual to expected performance is apparently no greater for condensers operated with high water velocities than for those operated at the lower velocities.

The average circulating water quantity and velocity were as follows for all condensers for which these data were reported:

	Two-pass Condensers	Single-pass Condensers
Lb. of circulating water per hr. per sq. ft. of surface..............	605	869
Lb. of circulating water per thousand B.t.u. transferred..........	101	113
Velocity of water in tubes, ft. per sec.	6.3	6.25

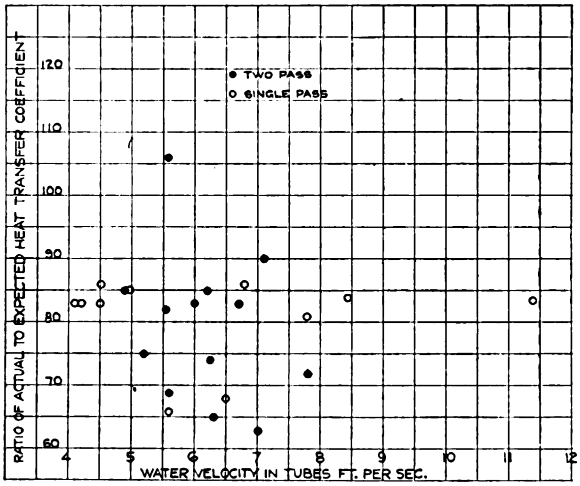

FIG. 4—RELATION OF WATER VELOCITY TO THE RATIO OF ACTUAL TO EXPECTED HEAT TRANSFER COEFFICIENT.

Power Consumption of Circulating Pumps

Circulating pump power consumption data were not available for all condensers. For the seven two-pass and nine single-pass condensers for which data were reported, the average consumption and water quantities were as follows:

	Two-pass Condensers	Single-pass Condensers
Circulating pump power consumption, kw. per 100 sq. ft..........	7.2	6.9
Circulating pump energy consumption in kw-hr. per million B.t.u. of heat transferred............	1.24	.94

	Two-pass Condensers	Single-pass Condensers
Lb. of circulating water per hr. per sq. ft. of surface................	590	796
Lb. of circulating water per 1000 B.t.u. of heat transferred.......	102	111
Velocity of water in tubes, ft. per sec.	6.2	5.7

Although a smaller quantity of water is used in two-pass condensers, the power consumption is greater probably on account of the higher friction drop through the condenser.

Effect of Circulating Water Temperature on Heat Transfer

The effect of the inlet circulating water temperature on performance is shown by comparing the values of heat transfer coefficient corrected to 6 ft. per sec. water velocity. For the cases where data are available over the range of temperature from 35 to 70 deg. fahr. the heat transfer coefficient varies as follows:

Average Heat Transfer Coefficient in Per Cent of Value with 35 deg. fahr. Inlet Circulating Water Temperature

Inlet circulating water temperature, deg. fahr.	55	70
Single-pass condensers	138	164
Two-pass condensers	138	178
Two-pass vertical condensers................	130	186

Cleaning of Condenser Tubes

Considerable variation in the frequency of tube cleaning is noted: For two of the installations no cleanings are reported, whereas five of the twenty-six condensers were cleaned more than fifty times during the year. Investigations show there is no definite relation between frequency of cleaning and the ratio of actual to expected heat transfer. Several of the installations showing the poorest performance were cleaned most frequently; both of the installations for which no cleanings were reported showed a comparatively high ratio of actual to expected heat transfer; and of the five which were cleaned more than fifty times during the year, one gave a low performance as compared with the expected, one an average performance, one a relatively good performance, and the remaining two gave performance appreciably better than the expected.

The average frequency of cleaning of two-pass installations was approximately 29 times per year as compared to approximately 15 times for single-pass condensers. The high average for the two-pass condensers is due to some of these units being cleaned a great deal more frequently than the other condensers of this type.

Rubber plugs were used either alone or in addition to other methods of cleaning in eighteen out of the twenty-four condensers for which cleaning data were reported.

Metallic cleaners were used in cleaning four condensers. In the case of three of these four condensers the metallic condensers were used almost exclusively, while in the fourth condenser the metallic cleaners were used six times and the rubber plugs sixty-six times. Four of the condensers were cleaned once and two others were cleaned several times during the year with chemical solutions to remove deposits on the water side of the tubes. In two cases the chemical solution was the only cleaning given and in the others this method of cleaning was used in addition to shooting with rubber plugs or cleaning by washing with water.

Sand blasting was performed on two installations which, in addition, used other methods of cleaning. One company reports that the tubes are cleaned regularly with water and air. Another company, taking water from the Chicago Drainage Canal, cleans the tubes by washing with water. Both cold and hot water have been used. Hot water has been found more effective.

Circulating Water Leakage

In all but two cases where circulating water leakage is reported, it is either negligibly small or less than 0.3 per cent of the condensate. The accuracy of the leakage data is not such as to make possible a comparison of the effectiveness of the various types of packing. It appears, however, that satisfactory results can be obtained with any one of the types of packing reported when it is properly used and when tube vibration does not occur.

Air Leakage

The values of air leakage reported range from 2 to 15 cu. ft. per min., the average being approximately 5 cu. ft. per min. Only four installations, however, report leakage in excess of 5 cu. ft. per min. The air leakage reported was in nearly all cases between 2 and 6 cu. ft. per min. It is impossible to show the relation between air leakage and condenser performance since the effect of air leakage is small in comparison with the effects of other variables.

Depression of the Condensate Temperature

Depression of the condensate temperature reported ranges from 0 to 19 deg. fahr. The average for single-pass condensers is 4.1 deg. fahr. and for two-pass condensers 1.6 deg. fahr. The higher average depression of the single-pass condensers results from the inclusion of two condensers, with a depression appreciably higher than the average of the other nine single pass installations. Eleven of the fifteen two-pass condensers and seven of the eleven single-pass condensers show an average depression of less than 2 deg. fahr. However, in many cases the depression is reduced as a result of the discharge of hot drains from heaters and air ejector condensers into the main condenser hotwell. No definite relation shows between the depression and the air leakage.

OPERATING COMPANY STATEMENTS

STATEMENT BY THE W. S. BARSTOW & COMPANY, READING, PA.

The performance of condensers No. 1 and 2 at Parr Station are shown in Fig. 5 and 6, and Table V and VI; of condensers No. 1 and 2 at the Middletown Station in Fig. 7-8, and Tables VII and VIII; and of No. 6 condenser at the Binghamton Station in Fig. 9 and Table IX.

The circulating water piping for No. 6 condenser at Binghamton is arranged for reversing the flow of the circulating water while the unit is in operation, consequently this condenser shows a better ratio of actual to expected heat transfer and less frequent cleaning of the tubes.

STATEMENT BY THE CLEVELAND ELECTRIC ILLUMINATING COMPANY, CLEVELAND, OHIO

Table I includes design data for condensers No. 1 and 2 at the Avon Station of the Cleveland Electric Illuminating Company which were installed in August, 1926. Condensers No. 1 and 2 are identical in design; No. 3 differs from these in tube sheet lay-out, although it is quite similar to No. 1 and 2 in surface, water quantity and number and length of tubes.

Performance data are given in Tables X, XI, and Fig. 10-11 for condensers No. 1 and 2 and on Table XII for No..3. Expected performance is from manufacturers' data and is the same for all units. Actual performance is based on half hourly readings taken from the oiler's log sheet. The actual heat transfer rate is determined from the average monthly values of vacuum, water temperatures, load and other pertinent data.

Capillary depression of the mercury column is recognized as an error in these calculations, although the magnitude is kept small by the use of special large bore tubes. No correction has been made in the data for test and experimental operation at arbitrarily high back pressures obtained by air bleeding. A third source of error lies in the use of average values of load, vacuum and water temperatures to calculate the average transfer rates, rather than to use an average of the rates as calculated for each of the half hourly periods. All errors introduced are of such a nature as to make the reported per cent of expected performance actually realized too low.

The operation of the condensers is quite satisfactory. Water leakage is easily kept to the values shown, air leakage is uniformly low and no cleaning has been found necessary. No tube failures have occurred. No. 4 condenser to be installed in 1929 will be identical with No. 3.

> NOTE—As the temperature rise of the circulating water at this station is low, the difference between "Log. Mean" as given in the tables and the "Arith. Mean" is within the accuracy of the data. Therefore "Arith. Coef. heat transfer" has been compared directly with "Expected coef. heat transfer (Log)."

STATEMENT BY THE COLUMBIA POWER COMPANY, CINCINNATI, OHIO

Description of Installation

Condenser No. 1 at the Columbia Power Station is a Worthington inclined vertical condenser with 48,000 sq. ft. of surface; it was installed during 1925 and was put into operation during December, 1925. Table II gives design characteristics of this condenser.

The condenser shell and tube bank are set on an angle of 35 deg. from vertical. Condensate is drained from the two tube support sheets directly to the hot well. Air removal apparatus consists of Worthington hydraulic vacuum pumps. Two circulating pumps are provided for the condenser, each driven by a constant speed squirrel cage motor.

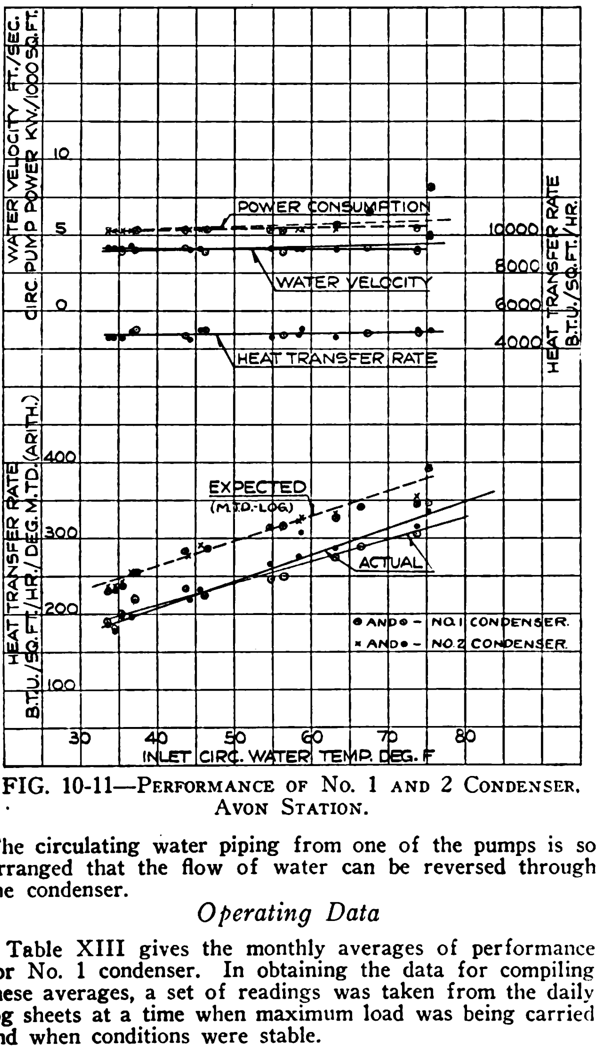

FIG. 10-11—PERFORMANCE OF NO. 1 AND 2 CONDENSER, AVON STATION.

The circulating water piping from one of the pumps is so arranged that the flow of water can be reversed through the condenser.

Operating Data

Table XIII gives the monthly averages of performance for No. 1 condenser. In obtaining the data for compiling these averages, a set of readings was taken from the daily log sheets at a time when maximum load was being carried and when conditions were stable.

During the months of October and November the maximum load that was carried gradually decreased, which is indicated by the heat transferred per hr. per sq. ft. of surface.

The amount of steam condensed was obtained from condensate flow meter data. The flow meter is installed in the condensate discharge line. The readings were checked against turbine steam flow data obtained from steam flow meter charts.

The river water leakage is determined by the electrical method. Readings of the condensate are the same as readings obtained from steam condensed in the 18th stage heater. The similarity of the readings indicates zero river water leakage into the condenser.

The data for air leakage were not taken during the year. A test of this leakage in December, 1928, gave a value of 2.14 cu. ft. per min. The monthly average of 2.25 as given in the table is based entirely upon the test value obtained.

During the months when both one and two circulating

R—Condenser cleaned with rubber plugs.

pumps were operated, the data were averaged not as a whole, but were separated into one and two pump operation averages. The data are given in Table XIII as separate averages.

Fig. 13 shows the actual monthly average heat transfer rate plotted against river water temperature. The expected heat transfer rate with clean tubes is also given. In the case of the actual data, the heat transfer rates were corrected to the condition when 313,000 lb. of steam per hr. are condensed. The corrected heat transfer rates are given in column 8A of Table XIII.

Since the condenser tubes have been cleaned only twice since installing the condenser, heat transfer data on condensers with clean tubes are rather limited. Above the river water temperature of 58 deg. fahr. no data with clean tubes are available. The curve showing heat transfer values with clean tubes above this temperature is drawn parallel to the actual operation data and may vary somewhat from the real values.

STATEMENT OF THE COMMONWEALTH EDISON COMPANY, CHICAGO, ILL.

Table II includes design characteristics of condensers Nos. 4 and 5 at the Crawford Avenue Station. These are Worthington units of 70,520 sq. ft. and 70,000 sq. ft. respectively, condenser No. 4 having been installed in 1926 and No. 5 in 1927.

The performance values given in Fig. 14 and 15, and Tables XIV and XV are based on monthly averages of hourly condenser readings. The quantity of circulating water was determined from the temperature rise, and the amount of steam condensed based on the steam distribution at the given average load of turbine. It will be noted that this circulating water quantity is practically constant, which is due to the fact that the pumps are normally running at full speed, thus maintaining a high and constant water quantity and velocity. This keeps the condensers clean for a longer period. Each of the two circulating water pumps on condenser No. 4 are driven with variable speed motors, while those on condenser No. 5 are driven with two, two-speed motors. However, the pump speed is reduced to about 75 per cent of its full value only in case the loads of No. 4 and 5 drop below 40,000 kw. and 50,000 kw. respectively. It was found that the saving in pump power consumption due to speed reduction does not outweigh the loss due to lower vacuum.

The expected heat transfer values shown are based on the manufacturers' guarantees. Corrections were made for the variation in load, inlet water temperature and quantity of circulating water from the guaranteed values. It will be noted that with the exception of a few months on No. 4 and one month on No. 5 the average actual heat transfer is higher than the expected value. This is largely due to the fact that the actual obtained vacua are better than the guaranteed values at the corresponding loads. The guaranteed vacua throughout the given range of load are not less than 1 in. Hg.

In addition to the above expected values, Tables XIV and XV show heat transfer values which were based on computed maximum possible vacua of clean condensers, condensing air free steam, taking into account the variation in load, velocity and mean temperature of circulating water.

The condensers cannot be cleaned while in service except by back-washing and lancing which was normally done with cold water alone or cold water and a chemical compound. The cold water was recently replaced by hot water since this speeds up the cleaning process considerably.

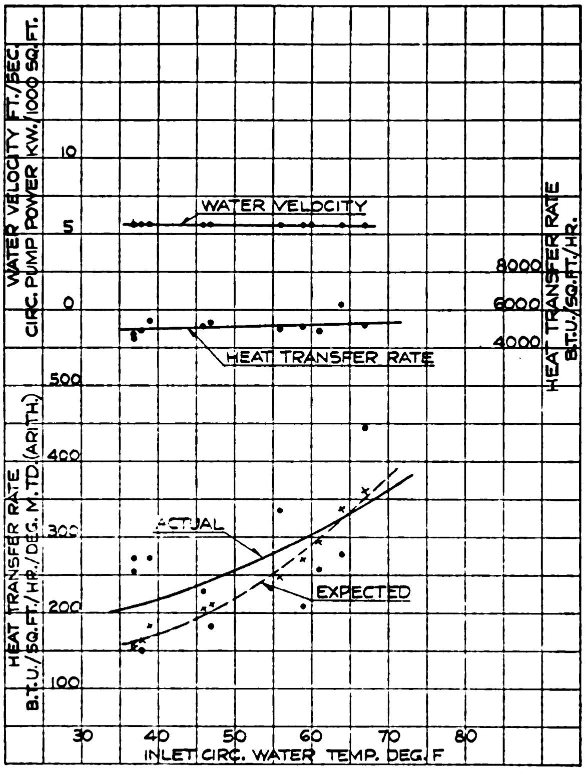

FIG. 14—PERFORMANCE OF NO. 4 CONDENSER, CRAWFORD AVENUE STATION.

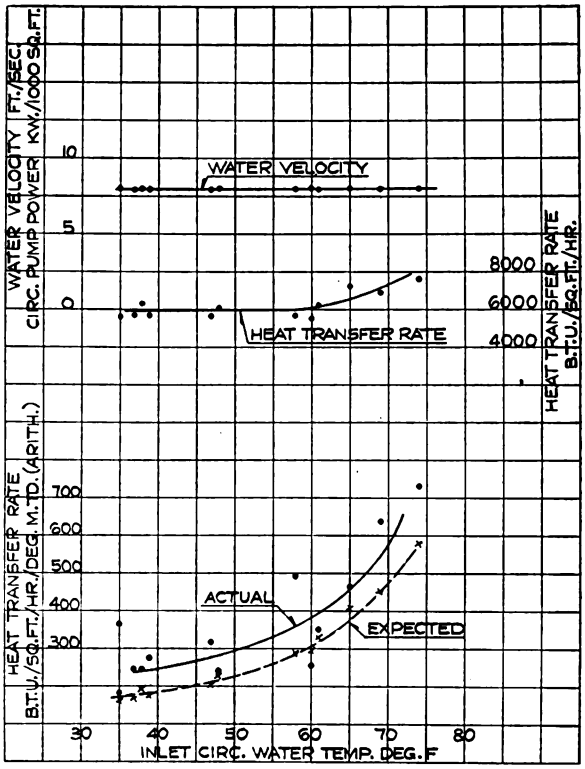

FIG. 15—PERFORMANCE OF NO. 5 CONDENSER, CRAWFORD AVENUE STATION.

The hot water cleaning is usually done over the week-end as load conditions at the station make cleaning impossible at other times.

STATEMENT BY THE DETROIT EDISON COMPANY, DETROIT, MICH.

Design

Condensers No. 4 and 5 at the Trenton Channel Plant were installed during the years 1926 and 1927 respectively. They are identical 51,500 sq. ft., single-pass, Worthington units.

The condenser tube sheets are set concentric with the shell and the tubes are spaced equally, with large wedge-shaped sections of tubes omitted to provide steam lanes.

Approximately one-quarter of the condenser surface is set apart as an air cooler, separated from the steam condensing section by suitable baffles. The air is removed through a header which runs longitudinally through the center of the condenser.

Each condenser is served by two 60,000 g.p.m. circulating water pumps, each pump being driven by a 240-volt, d-c., 325-h.p. motor having a speed range of 175 to 255 r.p.m.

Operating Data

Fig. 16 and 17, and Tables XVI and XVII gives the monthly averages of daily observations of performance of

No. 4 and 5 units for the period of January to November, inclusive, 1928.

Hourly observations made by the operating force are recorded on logs. The tables are based on these observations. In order to minimize the effect of variations of load, only those observations have been considered which were made when the machine load was relatively constant, and between 40,000 and 45,000 kw.

The quantity of water condensed per hour was computed from the kilowatt load carrier by the turbine. In computing the quantity of heat transferred per hour, account was taken of the fact that the total water condensed enters the condenser partially as exhaust steam from the turbine, and partially as drip from the extraction heaters.

There are two methods available for computing the quantity of circulating water: (1) From the quantity of water condensed and the temperature rise of the circulating water, and (2) from the power consumption of the circulating pump motors. At the present time, No. 4 and 5 condensers are equipped with gas-filled thermometers indicating, on one dial, both the inlet and the outlet circulating water temperature. However, for the greater part of the year, the water temperatures were indicated by mercury thermometers of the industrial type. Inasmuch as the relation between power consumption and quantity of water pumped is known rather accurately as a result of extensive pump tests, it was felt that this method, (2), was preferable to the temperature rise method and has accordingly been used.

The temperature rise of the circulating water as recorded in Tables XVI and XVII is that which would result from

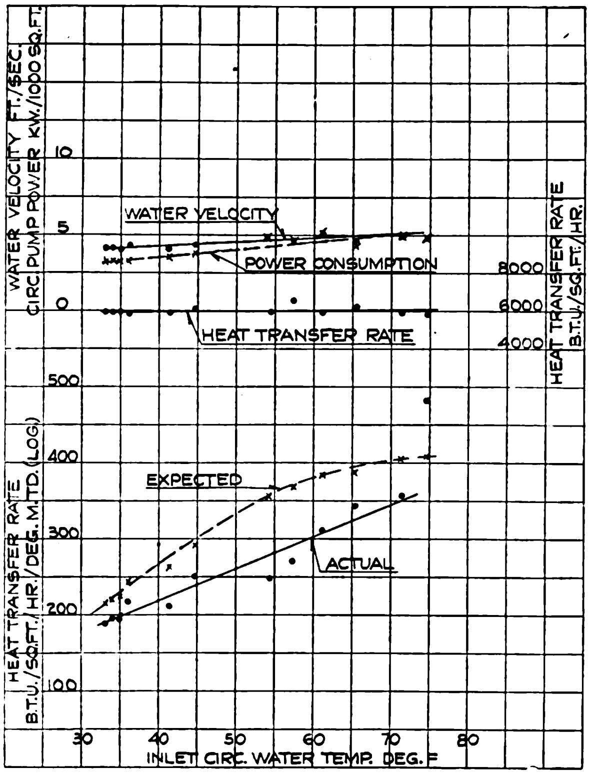

FIG. 16—PERFORMANCE OF NO. 4 CONDENSER, TRENTON CHANNEL STATION.

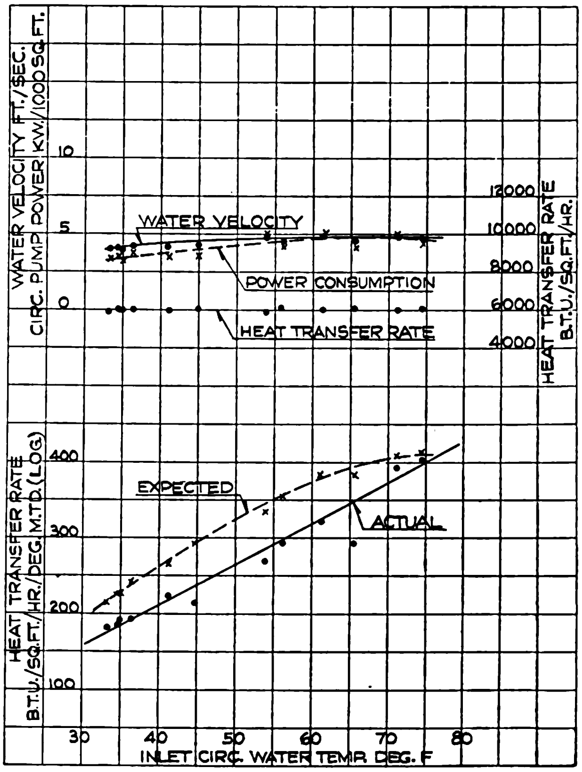

FIG. 17—PERFORMANCE OF NO. 5 CONDENSER, TRENTON CHANNEL STATION.

the circulation of the recorded amount of circulating water as determined from the power consumption of the pump motors.

The expected heat transfer coefficients with clean tubes, as recorded in the tables, take account of the quantity of steam condensed, the inlet circulating water temperature and the quantity of circulating water. Actual heat transfer coefficients are, of course, lower than the coefficients expected with clean tubes. An exception to this statement will be noted in the case of No. 4 unit for the month of August, when the ratio of actual to expected heat transfer was 1.18. However, the unit was in service for only 71 hr. during the month, after being taken out of service during July for annual overhauling. The tubes were washed on July 31, while the overhauling was in progress. The data for No. 4 unit in August are not representative of operating conditions and have not been considered in plotting the heat transfer coefficient curves for No. 4 unit.

Air and Water Leakage

While results of air leakage tests are not available for all months, the results given are representative of year-around operation. No difficulty has been experienced in keeping air leakage below 5 cu. ft. per min.

No figures for percentage of leakage of circulating water into the condenser appear in the table, although samples of condensate from each unit are tested every other day. The ratings on the Dionic water tester when testing condensate from units No. 4 and 5 average 2.0, with individual samples showing from 1.5 to 2.5 units. Inasmuch as samples of steam main drips show approximately 2.0 units on the Dionic water tester, it can be concluded that there was practically no in-leakage of circulating water into these condensers. Experience has shown that a few loose condenser tube glands will cause the condensate to increase to about 4 to 5 units on the Dionic water tester, whereas a split tube may increase the conductivity to 10 units.

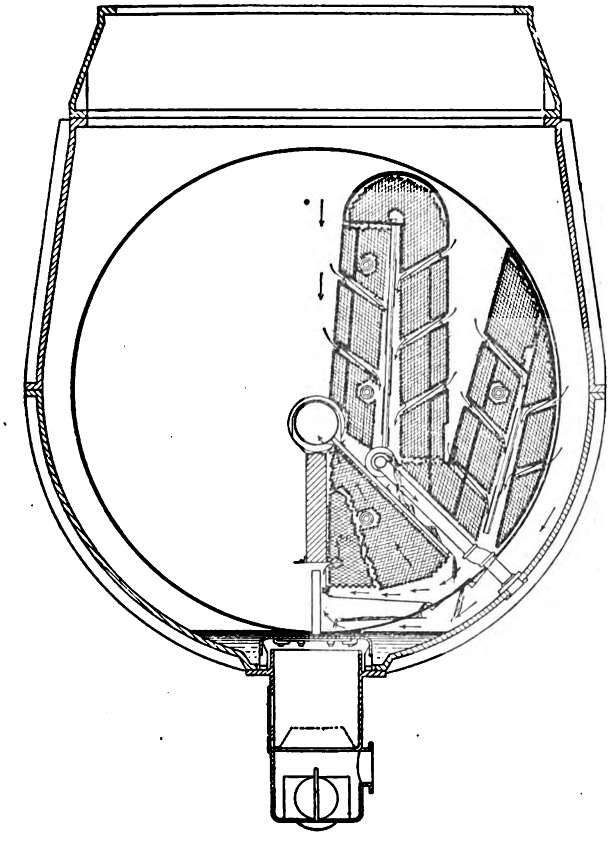

FIG. 17-A—ADDITIONAL TUBE SUPPORTS OF NO. 4 AND 5 CONDENSERS, TRENTON CHANNEL STATION.

Originally some trouble was experienced with tubes in these two condensers leaking due to holes having been worn in them by vibration of the tubes. This was first detected by an excessive number of leaks around the packing glands of the tubes on the outside of the tube banks. The first three units in this plant had condensers with three tube support plates, but those of units No. 4 and 5 had only two tube support plates. No trouble was experienced due to vibration of the tubes in the first units, but on these two units the tubes were worn so thin in the tube support plates that in some cases holes were worn through, and in the tube packing that the thin wall of the tubes crumpled within the packing when it was tightened. Three sets of sector tube support plates were installed between the original tube support plates and tube heads, giving the tubes within the areas, heavily outlined in Fig. 17A, five points of support between the tube heads. During the three months of operation since these additional support plates were added, no trouble has been experienced due to vibration.

STATEMENT BY THE DUQUESNE LIGHT COMPANY, PITTSBURGH, PA.

No. 3-A and 3-B units at Colfax were installed during the year 1924. Each unit is served by a Westinghouse 55,000-sq. ft. radial flow condenser having a divided water box so as to permit cleaning while in service (see Table II).

Each condenser is equipped with two 47,000-g.p.m. circulating pumps driven by constant speed induction motors. The amount of circulating water delivered to the condensers cannot be varied, except by changing the number of pumps in service.

Fig. 18-19 and Tables XVIII and XIX give the monthly performance of the condensers during the year 1928. These results are based upon the hourly readings taken from the regular operating instruments by the operators. The expected heat transfer is taken from the manufacturer's guarantee.

The leakage of circulating water into the condensate is

*R—Cleaning with rubber plugs.
M—Cleaning with metal plugs.

determined by a conductivity meter, the cells being located in the hotwells of the condensers. No trouble has been experienced with excessive leakage.

The air leakage is determined by the orifice method, a recording gage giving a continuous record of the leakage. The leakage as reported also includes the leakage and noncondensible gases of the bleeder heaters, as these heaters are vented to various parts of the turbines.

The schedule of cleaning tubes is dependent upon the cost of cleaning and the resulting increase in economy. Both rubber and metal tube cleaners are used. During the summer time the rubber cleaners are used, due to the rapidity with which the tubes can be cleaned. During the winter time, when the fouling of the tubes is less rapid, the metal cleaners are used periodically, as this type removes practically all dirt and scale down to the metal, and results in a better heat transfer.

STATEMENT BY THE EDISON ELECTRIC ILLUMINATING COMPANY, BOSTON, MASS.

Condensers No. 1 and No. 2 at the Edgar Station went into service early in 1925. These are identical 45,232-sq. ft. Worthington condensers for two 32,000-kw. General Electric. 350-lb., 700-deg. fahr. turbines. Table II includes a number of the condenser design characteristics.

Hourly readings, which are averaged daily, weekly and monthly, are taken by the operating crews of the important condenser temperatures in the stations. Venturi meters are installed to measure the condensate flow, but as these meters are recording, no hourly readings are available. The water condensed has, therefore, been taken as a function of the turbine load from data previously prepared. The quantity of circulating water is determined by a condenser heat balance.

Fig. 20 and Table XX give the monthly averages of the hourly readings. The expected heat transfer values are based upon data supplied by the manufacturer for the preparation of an operating "bogey."

Various methods of cleaning condensers with different designs of plugs and by blowing with air and water have been tried at the L Street Station. Finally a plug has been developed which promises to give results. Heretofore there has been no appreciable gain in heat transfer through the use of ordinary solid rubber plugs, but they have been found effective in removing mussel shells and mud from the tubes. At Edgar Station, where the attached data were collected, the conditions do not warrant frequent cleaning with solid rubber plugs.

STATEMENT BY THE INDIANA & MICHIGAN ELECTRIC COMPANY, CHICAGO, ILL.

Condensers No. 1 and 2 at the Twin Branch Station were installed during the year 1925. These are identical Wheeler condensers of the horizontal, single-pass type. They each have 25,720 sq. ft. of cooling surface with provision for 30,000 sq. ft. No circulating water pumps are installed at this station, due to utilizing the 24-ft. head of water created by the dam at the existing hydro electric plant on the St. Joseph River at this point. Table I includes a number of the design characteristics.

NOTE:—*No depression due to hot drains emptying into hotwell.
**R denotes cleaning with rubber plugs.

Operating Results

Daily observations are made of the performance of all the condensing equipment at the Twin Branch Station. These observations are made by a member of the test organization at a time when the turbines are heavily loaded. Steam condensed is measured by Bailey flow meters. The quantity of circulating water is determined from the quantity of steam condensed and the temperature rise of the circulating water.

Fig. 21 and Table XXI give the monthly averages of daily observations of performance. The expected heat transfer values are based on the manufacturer's guarantee. From the daily observations of performance, the difference between the actual and expected vacua are determined. This value is of use in determining when it is economic to clean the condenser tubes.

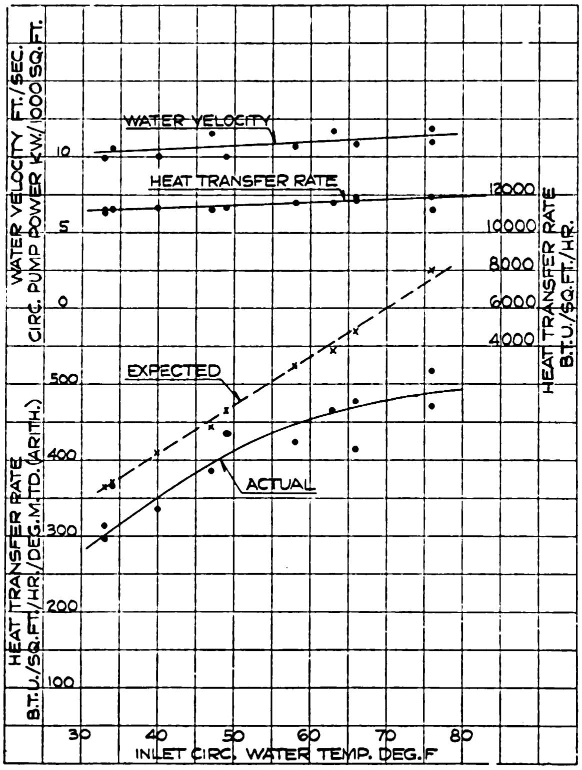

FIG. 21—PERFORMANCE OF NO. 2 CONDENSER, TWIN BRANCH STATION.

As has been said before, no circulating water pumps are necessary due to an existing dam. The top of the dam and the tops of the condensers are at the same elevation, producing an adequate flow of circulating water. Regulation of circulating water is accomplished by throttling the discharge valves of the condensers. Due to the excellent quality of circulating water, not much trouble is experienced with dirty tubes.

Reversal of Circulating Water

These condensers are so designed that the flow of circulating water can be reversed with the machine in service. The flow has been reversed with as much as 10,000 kw. on the turbine with only momentary depression of vacuum. One water box is provided with a 48-in. inlet and 60-in. outlet, and the other is provided with a 60-in. inlet and 48-in. outlet. With the proper manipulation of the intake and discharge valves, the flow can be reversed. However, due to ½-in. mesh traveling screens located at the crib house, reversing has not been found necessary, as any trash which passes through the screens will pass through the tubes.

STATEMENT BY THE MILWAUKEE ELECTRIC RAILWAY & LIGHT COMPANY, MILWAUKEE, WIS.

The condenser installed in the latter part of 1926 with No. 6 unit (30,000 kw.) at Lakeside is a Wheeler single-pass, with 25,000 sq. ft. of surface.

Hourly readings of significant data are taken by the operators, from which Fig. 22 and Table XXII was prepared. Heat input to the condenser was calculated from turbine loads. The expected performance is based on guarantees which were for one circulating water temperature only, but a curve following the trend of observed data and passing through the guarantee point was constructed. Since the unit has been operated throughout the year as a base load unit, no corrections were necessary for load variations. Corrections were made for variations in circulating water temperature.

Raw water leakage into the condenser has been difficult to maintain desirably low. The tubes are rolled at one end and packed with corset lace packing at the other. The ferrules have now been taken up as much as possible, so

that condenser must be entirely repacked in the near future. Leakage lower than about 0.4 per cent cannot now be obtained.

STATEMENT BY THE NEW YORK EDISON COMPANY, NEW YORK, N. Y.

Condensers No. 1 and 2 at the East River Station were installed during the year 1927 and are identical, being of the single-pass type with single water boxes, and were manufactured by the Foster-Wheeler Corp. Each has 47,500 sq. ft. of surface and is supplied by two turbine driven circulating water pumps, each having a capacity of 45,000 g.p.m. These pump turbines operate condensing. Table I includes some design characteristics.

Table No. XXIII gives the monthly averages of daily observations of performance. Fig. 23 gives a comparison of the performance data for the condenser.

The tubes are cleaned regularly with air and water every other night and by sandblasting twice a year.

†No data available.

A constant check of the condition of the condensate is maintained by a salinity indicator, and titration tests are made every two hours.

A constant vacuum is maintained on the tail-pipes.

STATEMENT BY THE NORTHERN STATES POWER COMPANY OF MINNEAPOLIS, MINN.

No. 1 condenser at High Bridge Station was installed in 1924, has 40,000 sq. ft. of cooling surface, serves a 30,000-kw., 17-stage, G. E. turbine and was built by Worthington. Table II includes design characteristics.

Table XXIV gaves the monthly averages of the performance for a load of 24,000 kw., as indicated by the operating records. These data were collected from the daily operating records and are, therefore, not of a high degree of accuracy, but every effort was made to eliminate the effect of observational error. The quantity of the condensate was taken from the condensate meter, and the amount of circulating water was assumed to remain constant since the pump runs at constant speed.

The curve of the actual monthly averages of the coefficient of heat transfer is shown, together with the curve of expected coefficient of heat transfer in Fig. 24. The expected heat transfer values, based on manufacturer's guarantees, were not available; therefore the values shown were calculated from the expected minimum absolute pressure as determined by condenser performance immediately after cleaning. These values are, therefore, possibly a little higher than the manufacturer's guarantees would be. The expected minimum absolute pressure cannot be maintained in operation because the condenser tubes foul very quickly after cleaning.

TABLE XXIV

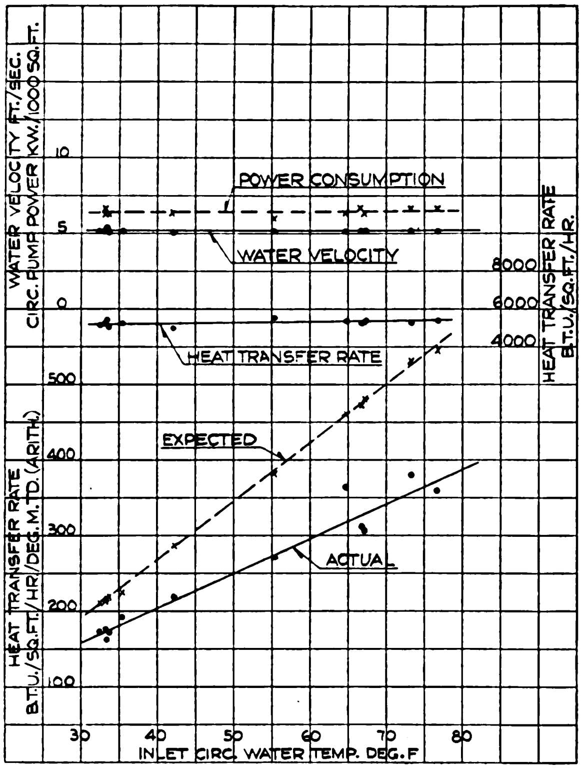

FIG. 24—PERFORMANCE OF NO. 1 CONDENSER, HIGH BRIDGE STATION.

Frequency of Cleaning

The condenser is cleaned by forcing rubber plugs through the tubes with an air gun. The rubber plugs have been very satisfactory in removing the soft, slimy deposit which collects in the tubes during operation. The frequency of cleaning depends upon the following considerations:

1. Difference between actual and expected vacuum.
2. Saving due to decreased absolute pressure.
3. Cost of cleaning.
4. Loss due to generating load on less efficient unit during cleaning period.
5. Rate at which tubes foul after cleaning.

It will be noted that the frequency of cleaning varies from 4 times per month in the winter to 10 times in the summer as shown in Table XXIV.

The condenser is equipped with one duplex driven circulating pump. Under normal conditions the motor drive is used. The steam turbine is used only for feed water heat balance or in case of electrical disturbances.

STATEMENT BY THE PENNSYLVANIA POWER & LIGHT COMPANY, ALLENTOWN, PA.

Description of Condenser and Cooling Pond

Condenser No. 3 was installed at Pine Grove early in 1926, is a 50,000-sq. ft., 2-pass, counter-flow, divided water box type, and was made by the Worthington Pump & Machinery Corp. The manufacturers specify 45,000 g.p.m. of circulating water at full load of 300,000 lb. of steam per hour; velocity of circulating water 5.2 ft. per second, based on 4340 tubes per pass. It is equipped with two sets of Worthington steam jet air removal pumps, either of which is capable of carrying off sufficient non-condensable vapor to maintain the expected vacuum under normal conditions. The condensate is removed from the hotwell by either of two motor-driven centrifugal pumps, each of which is large enough to carry the resultant condensate from a full load on the unit. Table II includes a number of the design characteristics.

The circulating water is handled by two motor-driven pumps. The motors may be run at either of two speeds, 442 r.p.m. or 294 r.p.m. Two-speed motors are used because of the two different methods of discharging the circulating water. This water may be returned to the cooling pond by use of a set of sprays, in which case the higher speed is used, or it may be pumped into a discharge water channel. The cold water discharged from the pumps enters the condenser from the bottom, passes through the lower tubes and returns through the upper tubes to the discharge lines.

A description of the layout of the cooling pond will explain the difference between the free discharge into the channel and the discharge through sprays. The pond is essentially rectangular, with its longer dimension north and south and is situated to the east of the plant. It serves two 12,500-kw. turbine condensers as well as the one under discussion. It receives its fresh water make up from the northeast corner, and the excess is discharged over a spillway at the southwest corner. Along the whole west side of the pond, and separated from it by a concrete wall, runs the discharge channel. The only connection in use during normal operation between the pond and the channel is at the southwest corner of the pond adjacent to the previously mentioned spillway, and there is no other outlet from the channel. With this arrangement it is readily seen that, when water is discharged into the channel, it can only run in one direction, and when water is plentiful and a large quantity is flowing over the spillway a large proportion of the discharge water will take this course. In dry weather, when water is scarce and very little finds its way over the spillway, the water from the channel flows into the body of the pond and eventually circulated back to the intake. The intake is situated approximately halfway up the length of the pond on the west side, and consists of an underground duct passing under the channel, and into a screen house equipped with traveling screens for removing the larger of the foreign materials carried along by the water. The circulating pumps take their suction from the screen house. The sprays are extended out over the greater portion of the surface of the pond, and the selection of spraying or channel discharge is accomplished by means of remote control motor operated valves.

Choice between the two methods of disposing of circulating water depends on the following conditions: Relative humidity, temperature of air and temperature of the pond; rather than on any consideration of station loading or other conditions within the plant.

It has been found by experiment that both circulating pumps are necessary for the most economic operation, regardless of whether the discharge is sprayed or emptied directly into the channel. With only one pump working, the vacuum in the condenser falls appreciably, but may be held at a sufficiently high value to allow a normal loading of the unit in case of emergency.

The condenser is equipped with a vacuum breaking line which is extended up to the level of the turbine operating floor, ending in a valve with a water seal. This is for convenience in shutting down the machine.

Due to the nature of the design of the unit as a whole, the quantity of water condensed in the main condenser is not equivalent to the quantity of steam fed to the turbine. Bleeding from the 7th, 11th and 14th stages of the turbine accounts for the difference. None of this extracted steam finds its way back to the main condenser.

Method of Obtaining Data

No daily records are available on the quantity of condensate removed from the hotwell, but there is a Builders Iron Foundry mercury manometer and venturi tube permanently installed for test purposes, so that it is possible to get this information at any time. Other condenser operating data are obtained by means of two 3-pen Foxboro recorders which include exhaust steam temperature, condensate temperature, and injection and discharge circulating water temperatures on each of the two sides of the con-

TABLE XXV

AVERAGE OPERATING PERFORMANCE OF NO. 3 CONDENSER
PINE GROVE STATION OF THE PENNSYLVANIA POWER & LIGHT COMPANY

YEAR 1928

1. Month	Jan.	Feb.	March	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
2. Heat transferred per hr. per sq. ft. of surface, B.t.u.	4,430	4,440	4,370	4,590	4,770	4,850	4,700	4,850	4,730	4,750	4,580	4,480
3. Lb. of circ. water per hr. per sq. ft. of surface	526	515	511	520	538	537	544	536	560	558	575	585
4. Av. velocity of circ. water in tubes, ft. per sec.	6.1	6.0	5.9	6.0	6.2	6.2	6.3	6.2	6.5	6.4	6.6	6.8
5. Inlet circ. water temp., °F.	65.7	58.0	65.2	68.2	76.0	81.6	82.9	88.4	82.9	80.0	74.2	68.3
6. Temp. rise of circ. water, °F.	8.3	8.7	8.6	8.9	8.8	9.0	8.7	9.1	8.4	8.5	8.0	7.7
7. Arithmetic mean temp. difference between circ. water and steam, °F.	16.2	20.5	15.9	18.7	18.7	18.9	12.9	14.9	15.7	16.4	13.7	13.2
8. Arithmetic coefficient of heat transfer	274	217	275	245	255	256	365	325	301	290	334	339
9. Expected heat transfer coefficient with clean tubes	378	369	361	379	397	400	402	397	404	405	394	396
10. Ratio of actual to expected heat transfer	0.73	0.59	0.76	0.65	0.64	0.64	0.91	0.82	0.74	0.72	0.85	0.86
11. Air leakage, cu. ft. per min.					Not	measu	red

13. Leakage of circ. water, %					Not	measu	red					
14. Frequency of and methods used in cleaning tubes	1	0	0	0	0	0	1	0	0	1	0	0
15. Hours in service	682	677	723	703	733	720	728	635	708	662	402	729
16. Power requirement of circ. water pumps, kw. per 1,000 sq. ft.					Not	measu	red					

denser. A Tyco barometric type mercurial vacuum gage equipped with a vernier is used to obtain the vacuum at the exhaust. These instruments, together with a high water alarm in the hotwell and the usual allotment of pressure and vacuum gages on the condenser and auxiliaries, furnish the operating guide and source of daily records. Also all necessary pipe lines have thermometer wells installed at convenient points for test work, so that all important temperatures may be observed on calibrated mercury thermometers.

In addition to the daily records, a test is run each week to determine the operating characteristics of the unit as a whole. All pertinent condenser data are taken in these tests, and the information derived consists of such items as coefficient of heat transfer, comparison of actual back pressure to expected back pressure in which corrections are made for injection water temperature, rise in temperature of the circulating water and quantity of steam handled; as well as those items more readily obtained through daily routine readings. Records of these tests are tabulated on specially designed report forms and the more important items are plotted in curve form, each year being included on one set of sheets. The tests are always run with the load on the unit as nearly the same from week to week as is possible, the only variations being due to governor characteristics, slight changes in system frequency, etc. The pre-arranged test load for unit No. 3 is 27,000 kw., which is the point of best economy, according to the manufacturer's specifications. At this load and with normal turbine stage bleeding conditions the condenser receives an average of about 240,000 lb. of steam per hour or 80 per cent of its rated capacity.

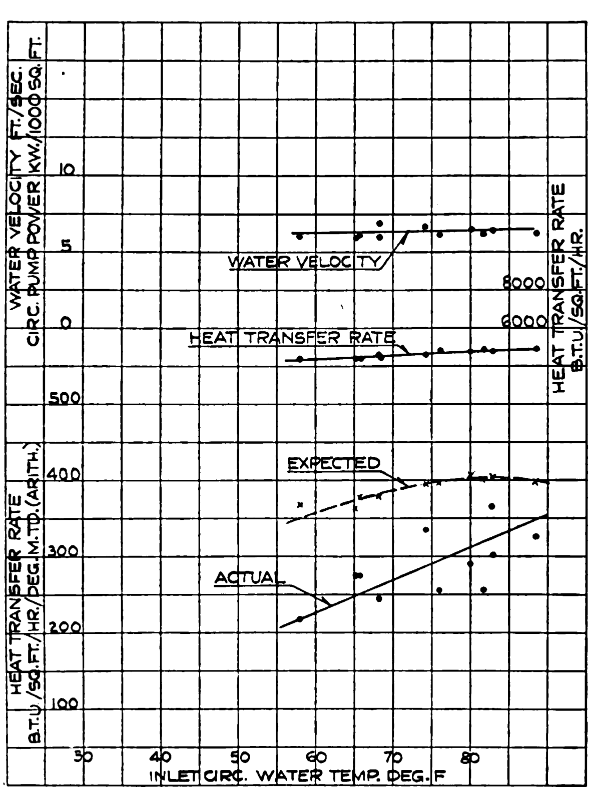

FIG. 25—PERFORMANCE OF NO. 3 CONDENSER, PINE GROVE STATION.

The tests just described form the basis for the operating data given in Fig. 25 and Table XXV.

With the back pressure largely dependent on the temperature of injection water and with the peculiar temperature characteristics of the cooling pond, the results of the weekly tests form an excellent basis for comparative condenser performance. Peculiar temperature characteristics of the spray pond refer to the fact that the water temperature is dependent on quantity of rainfall over a given period rather than on outside air temperature over that period. From this it will be seen that comparisons by months are not important, for although the average air temperature throughout any given month of a year may be similar to that of the same month of another year, the pond temperature may vary, due to difference in rainfall, to such an extent that condenser performance during these months will be entirely different.

The important parts of the daily records are also plotted up in curve form, similarly to the test data. The curves on condenser performance then form a part of the complete set of operating data curves giving information on all sections of the plant.

Cleaning of Tubes

The operation of the condenser has been very satisfactory. With clean tubes it is possible to approach very closely to the expected back pressure. For several weeks, under normal conditions, after a tube cleaning the difference between the actual and expected figures will run less than 0.10-in. Hg. This difference will increase until the next cleaning.

The water boxes of the condenser are cleaned periodically. As it is possible to operate with only one circulating pump and one-half of the condenser active, the other half may be cleaned while the unit is in operation but this method is not generally employed. Once a month, usually the last Sunday, the unit is taken out of service for miscellaneous work and the water boxes and tube sheets are cleaned at this time.

The tubes are cleaned by shooting rubber plugs through them with compressed air, approximately every three months. The unit is not removed from service for this job alone, but under circumstances similar to those mentioned in the preceding paragraph. On a few occasions a tube has been found to have worked loose, but, after tightening up the ferrules, tests have shown no indication of leakage. The tubes are ferruled at one end and are packed with corset lacing type packing.

No major troubles have been encountered. Occasional small air leaks have been discovered around pipe joints, and immediately patched up with shellac. In case of a large leak a temporary job was done with the shellac, and later at an opportune time the joint was renewed. A periodic water pressure test forms the principal method of detecting leaks.

STATEMENT BY THE PHILADELPHIA ELECTRIC COMPANY, PHILADELPHIA, PA.

Condensers No. 10 and 11 were installed at the Richmond Station during the year 1925. Design data are shown in Table II and operation data in Fig. 26 and 27 and Tables XXVI and XXVII.

Hourly readings of turbine load, circulating water temperatures entering and leaving the condensers, condensate flow, condensate temperature, barometer and condenser vacuum are taken in conjunction with other necessary plant readings. These data are assembled on plant log sheets for observation by the plant supervisors and for record in the central office.

Table XXVI and XXVII give the monthly averages resulting from readings taken from log sheets for one hour each day when the unit was carrying its average maximum load, or as near that value as could be obtained. The quantity of circulating water as given was computed from curves of heat absorbed by the water, obtained by assembling data given on numerous turbine tests and the actual temperature rise. The expected heat transfer rates as shown are based on manufacturers' guarantees. The other figures given are either actual instrument readings or values computed from such readings.

"The condensers are completely cleaned every two weeks, which results in our taking one unit out of service every week-end. Richmond Station has shown the lowest B.t.u. rate of any steam plant on the system, and it is found most economical in studying system loading to allocate most of the steam load to this station. Again by careful consideration of the monetary value of unit change in vacuum, average change in vacuum for a given time between cleanings, the cost of the cleaning and the loss due to outage of the units, the above schedule was found to be most feasible.

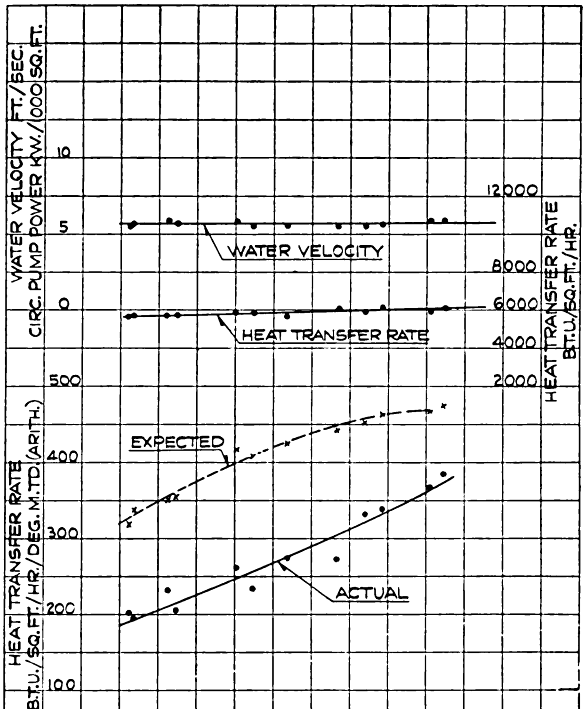

FIG. 27—PERFORMANCE OF NO. 11 CONDENSER, RICHMOND STATION.

No serious trouble has been encountered due to leakage of water, and continual vigilance on the part of the operators has kept the air leakage within reasonable limits.

STATEMENT BY THE PUBLIC SERVICE COMPANY OF COLORADO

No. 1 condenser at the Valmont Station, installed in November, 1924, is a Westinghouse horizontal two-pass surface condenser, laned around the outside of the tubes, with 30,000 sq. ft. of cooling surface including the air cooler.

No. 2 condenser was installed in October, 1926, is a two-pass Wheeler shallow type, 13 ft. 6 in. wide and 8 ft. deep, with 30,000 sq. ft. of surface. Tubes are arranged on the Wheeler multi pitch plan to allow a uniform distribution of steam throughout the condenser.

Both condensers are equipped with two circulating water pumps, one of which is dual driven by a constant speed a-c.

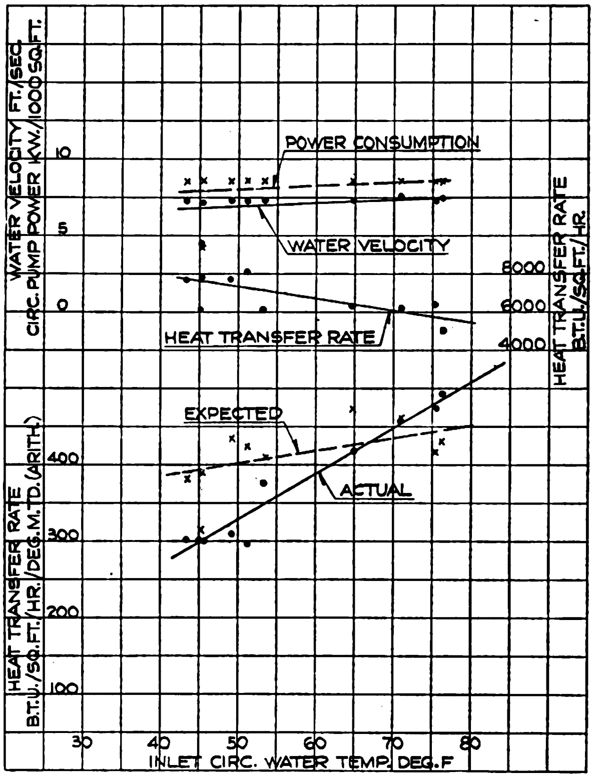

FIG. 29—PERFORMANCE OF NO. 2 CONDENSER, VALMONT STATION.

motor and a steam turbine. The other is driven by a constant speed a-c. motor. Thus there is either one or two pump operation, as conditions and economies warrant.

The data for the calculations in Fig. 28 and 29 and Tables XXVIII and XXIX were obtained from daily log sheets and recorder charts and averaged for each month; and, while not taken under test conditions can be considered fairly accurate.

The quantity of steam condensed was measured by means of a Bailey flow meter, which is periodically checked by weighed water tests.

The expected coefficients of heat transfer were calculated from manufacturers' guarantees and from tests run shortly after the condenser was installed.

A daily test for chlorides was run on the condensate, and it may safely be assumed from these tests that the condenser leakage did not exceed 0.3 per cent at the loads chosen.

The source of supply of circulating water is an 120-acre artificial lake supplied by water from the adjacent mountains. The water is free enough from organic and suspended matter, so that No. 1 condenser was in operation almost four years before it was considered to be in need of cleaning, a thin carbonate scale having formed in the tubes. This was removed by using a 10-per cent solution of muriatic acid.

STATEMENT BY THE TOLEDO EDISON COMPANY, TOLEDO, OHIO

The condenser on No. 3 unit at Acme Station, manufactured by the Wheeler Condenser & Engineering Corp. is 45,000 sq. ft. arranged for two passes of the circulating water. The more important design characteristics are included in Table II.

Observations for checking the performance of condensers at this station are made at frequent intervals. The quantity of circulating water is calculated from the turbine load and temperature rise of circulating water at the time of observation.

The important factor in determining when the condensers need cleaning is vacuum. Curves of standard performance covering the operating load range of the turbine have been plotted against vacuum and inlet temperature of circulating water, and from these curves comparison between expected vacuum and actual vacuum for any load can be readily made; and the degree of need for cleaning determined. Under average conditions a loss of 0.15 in. hg. vacuum over a period of one week will cause an increase in steam consumption equivalent to the cost of cleaning the condenser, so the condensers are cleaned over the week-end of the current week in which the vacuum reaches a point where it is 0.15 in. hg. low with usual day run load on the unit.

Average performance of the condenser on No. 3 turbine is given in Fig. 30 and Table XXX. The heat transfer rates secured in actual operation are less than expected in all cases, since the actual values represent the performance of tubes that are in just an average state of cleanliness.

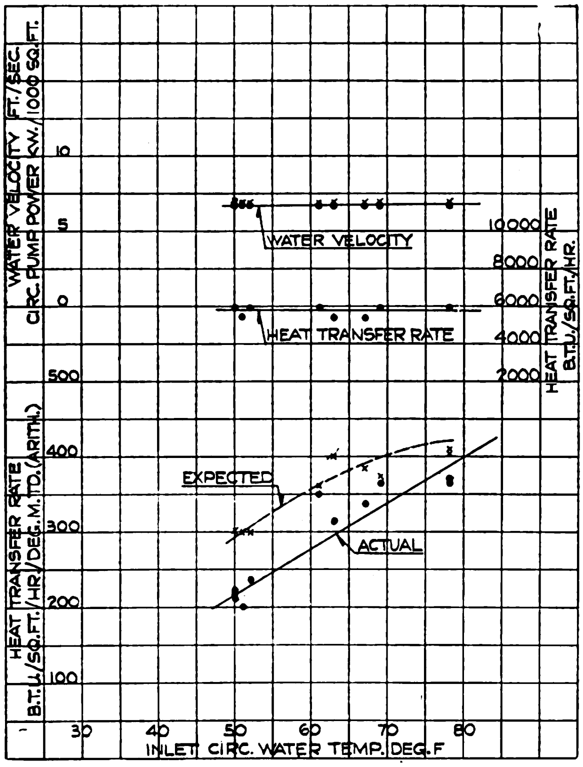

FIG. 30—PERFORMANCE OF NO. 3 CONDENSER, ACME STATION.

It will be noted that the difference between actual and expected heat transfer is greater during the winter months. This is due to an increase in the mean temperature difference between steam and circulating water caused by low circulating water temperature and does not mean that the total work done by the condenser during the winter is less than that done during the summer months.

Cleaning Condenser Tubes with Oakite

Performance of this condenser during the past five months shows considerable improvement over that for the first half of the year. This improvement in performance resulted from cleaning all tubes with a solution of test X Oakite. A solution of this material at about 180 deg. fahr. is passed through each tube. The tubes are then flushed out with hot water and shot with rubber plugs. The tube surfaces are left clean and smooth, and the performance of the condenser is restored almost to that of a new condenser.

Recirculation of Cooling Water

During the winter season the condensing water obtained from the Maumee River is at a low temperature. From December to February the water is always below 40 deg. fahr. and a greater portion of this time it is as low as 33 to 34 deg. fahr. Naturally this produces a considerable chilling of condensate, which reduces the overall economy of steam condensing and stage heating operation.

Early this year a plan was put into effect of recirculating condensing discharge water into the intake channel outside the screens in order to hold the temperature of inlet condensing water up to a point consistent with the best economy of steam condensing and stage heating combined.

Decreases in circulating water temperature bring about good substantial increases in vacuum down to a temperature of about 55 deg. fahr. Further decreases from this point down to the minimum of 33 deg. fahr. cause little or no improvement in vacuum, but lower the temperature of condensate leaving the hotwell. Since the low stage heaters heat the condensate to approximately saturation temperature of the bled steam, the depression in condensate temperature increases the amount of steam bled by the low stage heaters, and consequently the total steam consumption of the main units in restoring condensate temperature.

All circulating pumps at this station are duplex steam and electric driven and are arranged so that any desired ratio of load between the two drives can be obtained for the purpose of regulating the amount of exhaust steam to the deaerator heaters. Circulating water pumpage is constant throughout the year, it having been found that it is more profitable to recirculate condensing water and maintain the most economical balance between condensing and stage heating than it is to operate without recirculation of condensing water and reduce pumpage as the inlet temperature decreases.

No serious trouble from leakage has been experienced with this condenser. The amount of leakage present has not been a detriment due to the system of feeding all boilers, except one, with condensate since there has been no perceptible scale, and alkalinity has been maintained at a higher point than would be the case if there were no condenser leakage.

STATEMENT BY THE UNITED ELECTRIC LIGHT & POWER COMPANY, NEW YORK, N. Y.

Westinghouse condensers No. 6 and 7 at the Hell Gate Station, which are of the radial flow type and equipped with divided water boxes, were installed during 1924 and 1925. The condensing surface in No. 6 condenser is 63,000 sq. ft. and in No. 7 condenser 65,000 sq. ft.

Operating data for these condensers are given in Fig. 31 and 32, and Tables XXXI and XXXII.

The condenser performances were taken from the actual log sheet entries and, for each month, an average for the entire range of operation during that period was used. These figures, of course, do not give strictly correct results, but will show approximately the condenser performances. The quantity of circulating water was determined from the amount of steam condensed and the temperature

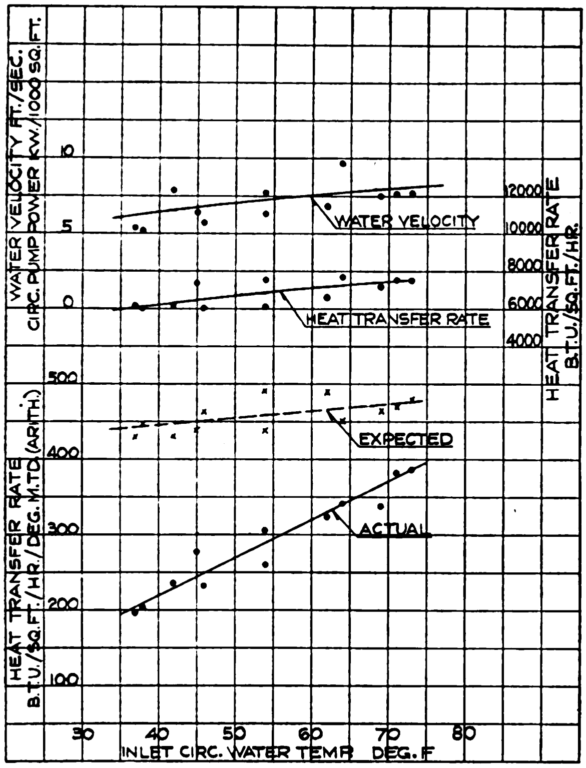

FIG. 32—PERFORMANCE OF NO. 7 CONDENSER, HELL GATE STATION.

rise of the circulating water. The amount of steam condensed was computed from the kw. load carried by the turbine and test water rates, the test water rates being corrected for average actual condition. In computing the heat transfers and velocity of circulating water in the tubes, the number of plugged tubes was taken into consideration.

As no individual power consumption data for the circulating pumps were available, these data had to be estimated from the service hours, high and low speed periods and kw. rating of the motors at high and low speeds. The per cent leakage of circulating water is kept so low that it may be considered negligible. The tubes in No. 6 condenser are ferruled, using corset lacing for packing at both ends, while No. 7 condenser tubes are rolled at the entrance end and ferruled at the other end.

Normally these condensers are not cleaned while in service. At times, however, it is necessary to make use of the divided water boxes while the unit is in operation in removing trash from the tube sheets.

As may be seen from Tables XXXI and XXXII, there is only a small amount of air leakage. Air is removed from the condenser by means of steam jet air evactors.

STATEMENT BY THE WEST PENN POWER COMPANY, PITTSBURGH, PA.

Condensers No. 3 and 4 at the Springdale Station were installed during the year 1924 and are identical 55,000-sq. ft. Westinghouse units of the radial flow type equipped with divided water boxes to permit cleaning while in operation. Table II includes a number of the design characteristics.

Daily observations are made of the performance of all of the condensers at the Springdale Station by a member of the test organization at a time of the day when the turbines are normally highly loaded. The loads on the individual turbines are held constant during the time the readings are taken. As facilities are not available for accurately measuring the steam condensed, this is computed from the kw. load carried by the turbine. The quantity of circulating water is determined from the amount of steam condensed and the temperature rise of the circulating water.

Table XXXIII gives the monthly averages of daily observations of performance. The monthly averages are also plotted in Fig. 33. The expected heat transfer values shown are based upon the manufacturer's guarantees. Correction is made for the variation in load, inlet water temperature and quantity of circulating water from the values upon which the guarantees were based. Performance equal to these expected values is obtained when the condenser tubes are cleaned and the air leakage is low.

It will be noted that, with the exception of one month, the average heat transfer is below the expected value with clean tubes. This lower heat transfer is permitted because the saving due to the improved vacuum is not considered sufficient to pay for the more frequent cleanings that would be required. It was found economical to clean the condenser

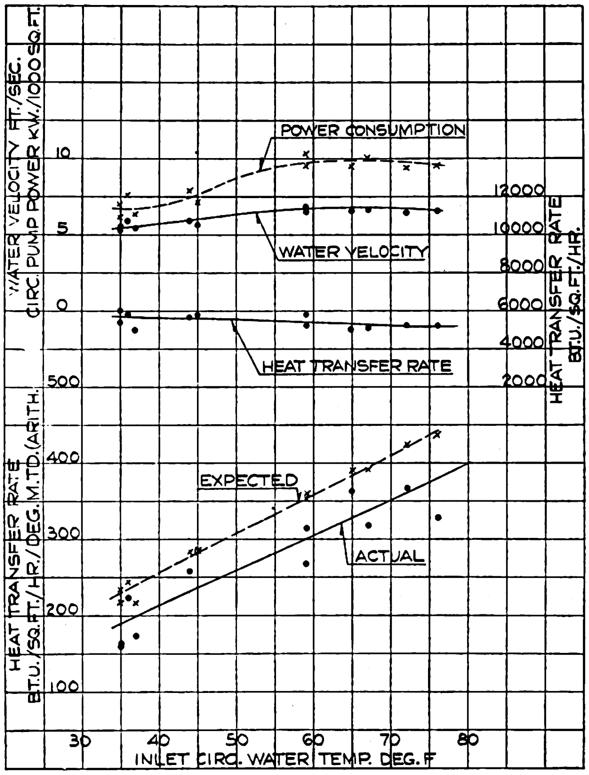

FIG. 33—PERFORMANCE OF NO. 3 CONDENSER, SPRINGDALE STATION.

tubes twice as frequently in the summer months as in the winter months.

From the daily observations of performance the difference between the actual and expected vacua are determined. This value is of use in determining when it is economical to clean the condenser tubes. The decision as to whether or not to clean the condenser tubes is based upon a consideration of the following data:

1. Difference between actual and expected vacua.
2. Saving in dollars per unit change in vacua.
3. Rate at which tubes will foul after cleaning.
4. Cost of cleaning.
5. Loss due to outage necessary to permit cleaning.

Each of the two circulating pumps with which No. 3 and No. 4 condensers are equipped are driven with variable speed motors. Although the degree of reliability of service required does not permit operation with only one pump in service, the motors are operated at 85 per cent of their full speed when calculations show the saving in circulating pump power consumption balances the loss in output of the turbo-generator. The variation of the circulating water during the different periods of the year will be noted in Table XXXIII.

Considerable difficulty has been experienced in maintaining the leakage of circulating water into the condenser at the desired low value. In both condensers the tubes are rolled at the inlet end and packed with fiber packing at the other end of the tubes. A great deal of attention is necessary to keep the leakage below 0.1 per cent. This trouble with leakage is thought to be due to a slight vibration of the condenser tubes which has, however, never been severe enough to damage them. The use of a heavier tube would probably greatly reduce the trouble with condenser leakage.

During the first year of operation when attempting to operate with one-half of the condenser open, the vacuum would fall so low as to make the condenser water boxes too warm to work in them. After reducing the air leakage to below 5 cu. ft. per min., no further trouble was experienced. The condensers are not normally cleaned while in service, since it is not found economical to clean more frequently than can be done when the unit is out of service for other reasons.

The divided water boxes are found of value in permitting the removal of trash from the tube sheets and making it possible to tighten the tube ferrules with the unit in operation. With heavier tubes or better bracing of the tubes there would probably be no need of tightening the ferrules more frequently than could be done at times when the unit is out of service.

TUBE VIBRATION AND CONDENSER LEAKAGE

Three member companies report that trouble has been experienced from tube vibration. In all cases, No. 18 gage tubes with two support plates were used. In two cases the vibration was severe enough to cause wearing of the tubes in the packing. In one of these two installations holes were worn through the tubes; in another excessive leakage resulted from the tube becoming loose in the packing or pulling loose at the rolled end.

The two severest cases of trouble were eliminated by the installation of tube support sheet sections so as to give the outer rows of tubes in the tube banks five points of support between the tube sheets. In the third case the installation of baffles and the driving of metallic and wooden wedges between the tubes has been tried without material reduction in the condenser leakage. Trouble of this kind is most noticeable with high vacuum operation and efficient turbines delivering exhaust steam with a large moisture content and is ordinarily more prevalent with circulating water temperatures below the average.

It has been suggested that tube vibration can be lessened by the use of heavier gage tubes. Of the condensers for which data are supplied in Tables I and II of this report, two are equipped with No. 16 gage tubes and three with No. 17 gage tubes. The condenser leakage for all of these condensers with heavy gage tubes is negligible.

Mr. Adolph Meyer of the Brown Boveri Company of Switzerland reports that in one case where tube vibration has been experienced with tubes of 1 mm. in thickness (about No. 18 gage) the trouble was remedied by replacing the outer top rows with tubes of 3 mm. thickness. Mr. Meyer also reports the installation of solid brass rods in the outer rows of tubes on which the moisture in the exhaust steam impinged. Moisture content of the steam was 12 per cent.

STATEMENT BY THE DETROIT EDISON COMPANY, DETROIT, MICH.

The Detroit Edison Company in their statement in this report on page 16, giving the operating results with units No. 4 and No. 5 at Trenton Channel, report trouble from tube vibration. They eliminated this by installing segmental plates to support the tubes in the upper section of the tube bank, thereby cutting the distance between original support plates in two.

STATEMENT BY THE UNION ELECTRIC LIGHT & POWER COMPANY, ST. LOUIS, MO.

During the past year this company has had experience with a 56,000-sq. ft. condenser in which excessive vibration was set up in the tubes by very high steam velocities incident to operation at high loads. The vibration caused the tubes to break and pull loose at the rolled end with consequent leakage. The condition was corrected by installing additional segments of tube support sheets spaced midway between the original sheets.

The trouble was noted after a few months' operation when condenser leakage increased abnormally. The condenser serves a 50,000-kw. turbine with an exhaust flow of about 470,000 lb. steam per hour at full load. It is 20 ft. long between tube sheets with two support sheets between, evenly spaced. The tubes, 1 in. O.D., 18 gage, were rolled at one end and packed with corset lacing packing at the other. The vibration caused the tubes to wear at the support sheets and to pull loose at the rolled end. At the other end the packing would hold tightly for a while, causing the tube to rub thin and the packing itself would then become loosened, and leakage would follow. Vibration was apparently severest across the top of the upper tube bank, adjacent to steam lanes, and along the outer four or five rows of tubes extending two-thirds of the way down to the hotwell.

Vibration was temporarily reduced by driving soft wooden slats down between the tubes where vibration was severest. The final solution as applied by the Worthington Pump & Machinery Corp. consists of sections of support sheets placed in three positions: Midway between the two original support sheets and midway between these sheets and the tube heads, thus making five support sheets in all. There are sixteen sections of new support sheets in each of the three positions—the sections being located so as to break up the vibration in the outer tubes which had been affected, and also in that portion of the tube bank which has not been affected. About 2700 of the 10,700 tubes have been given additional support. The additional supporting sheets are cast iron, finished all over with holes drilled and chamfered; maximum inside diameter, 1 1/64 in.; minimum diameter 0.002 less.

The arrangement proved effective, and since its installation no vibration trouble has been experienced.

STATEMENT BY THE WEST PENN POWER COMPANY, PITTSBURGH, PA.

Considerable difficulty has been experienced in keeping the leakage at the desired low value of below 0.1 per cent in the condensers at the Springdale Station. The leakage has been reduced to nearly this value in summer months, but in the winter months increases to a maximum of approximately 0.5 per cent. Condensers are opened about once a week for tightening the ferrules.

The tubes in the three largest condensers in the station are rolled into the tube sheet at one end and packed at the other with fiber packing. Although leakage is experienced at both the packed and rolled end, the leakage is materially greater at the packed end.

Leakage is greatest from the tubes impinged upon directly by the entering steam. This seemed to indicate that the leakage is caused by vibration of the tubes. The fact that the condenser leakage increases materially during the winter months when the steam velocity is highest tends to confirm the belief that the trouble is due to tube vibration. It was found upon inspection that the outer rows of tubes in the tube bank were covered with light spots, which were indicative of vibration. These condensers have two tube support plates, thus dividing the length of the tube into three sections, the outer two of which are approximately 7.5 ft. in length and the center approximately 5 ft. Vibration seemed to be confined almost entirely to the outer sections.

At the suggestion of the manufacturer, lattice-work bracing has been installed between the tubes in the two outer sections of two of the condensers. Originally bracing made of copper was used, but later wooden bracing was used, with the expectation that the swelling of the wood upon wetting would hold the tubes more firmly. In one of the condensers the bracing was installed in one direction only.

As no observable improvement was obtained from the bracing of the tubes, a baffle was installed in one of the condensers in order to deflect the steam from the direct flow into the condenser. Although this baffle was designed according to specifications received from the condenser manufacturer, no observable improvement in the condenser leakage has been obtained. At the present time the greatest leakage is in the lower half of the condenser, and baffling the steam so as to make more of it go into the upper half of the condenser is being considered, but has not yet been tried.

The circulating pumps are now being operated to cause the greatest flow of water through the half of the condenser which does not receive the direct flow of the steam. It is questionable whether this operation has resulted in any improvement.

The Duquesne Light Company has condensers of identical design with the exception that they are using No. 16 gage tubes in place of No. 18, and reports no vibration trouble or increased leakage during winter conditions.

EXPERIENCE WITH CONDENSERS HAVING TUBES ROLLED INTO TUBE SHEETS AT BOTH ENDS

Reports have been received from two companies having condensers with tubes rolled into the tube sheets at both ends. In one case a floating tube sheet at one end is used to provide for expansion and contraction. In the other, the stresses due to expansion are taken by the tubes and tube sheets. Leakage of circulating water into the condensate system has been found negligible in both cases and no unusual troubles are reported.

STATEMENT BY THE CONSOLIDATED GAS, ELECTRIC LIGHT & POWER COMPANY, BALTIMORE, MD.

The condenser serving the first unit at the Gould Street Station has been in service since December, 1926, while the condenser serving the second unit was placed in service in May, 1928.

These two-pass condensers are of Wheeler Condenser & Engineering Company manufacture, containing 30,000 sq. ft. of surface, each made up of 7363 tubes; ⅞ in. diameter, 18 gage. The exposed length of the tubes between tube sheets is 17 ft. 9½ in. The tubes are rolled in at both ends, the condenser being provided with no through stays. The stresses, due to pressure differences and to changes in temperature, are taken up entirely by the tubes and tube sheets.

The contamination of the condensate on account of circulating water leaking into the condensate system has always been a source of considerable annoyance due to the very poor quality of circulating water which is occasionally acid and which is always contaminated with a high percentage of organic matter as well as other industrial wastes. The leakage of circulating water into the condensate in the Gould Street condensers may be stated for all practical purposes as being nil.

The resistivity of the condensate, when tested with a standard Leeds & Northrup dip cell, is averaging well in excess of 1,000,000 ohms per cc., being apparently as high as samples of steam taken from a high-pressure steam line.

The average resistivity of condensate from the evaporator condenser, which uses condensate from the main unit as the condensing medium, shows an average resistivity of about 45,000 ohms per cc., despite the fact that the total dissolved solids in the concentrate is maintained at a very low figure.

The boilers in this plant have never been blown down since they were put in service. The total solids in solution in the boiler water have never exceeded 25 grains per gallon, the water being changed in the boilers on an average of once every two or three months, as it is then necessary to do work on the boilers which require the removal of the water.

There has been no trouble due to the loosening up of the tubes on account of starting up the unit on high pressure and establishing vacuum after the turbine has reached a speed sufficiently high to seal the shaft glands, which are of the water seal type.

In the first condenser it has been necessary to plug nine tubes since the unit was place in service, all of these tubes having failed due to defects which were well away from the ends of the tubes, and were apparently due to manufacture, the failures showing up either as split tubes or as very definite pit holes.

There seems to be much less corrosion of the tube ends than is the case with other condensers which are fitted with tubes rolled in at one end and packed at the other end with fiber packing. It is, of course, impossible to state whether this apparent slower rate of corrosion of tube ends is due to the fact that the tubes are rolled in at both ends, or to any one of a number of other conditions which may tend to minimize this particular difficulty.

STATEMENT BY THE TEXAS POWER & LIGHT COMPANY, DALLAS, TEX.

Two of the condensers at Trinidad Station are equipped with floating tube sheets and tubes rolled at both ends. These condensers have now been in service for two and one-half years. Shortly after operations were started there were two or three cases of tubes slipping due to these particular tubes not being properly rolled, an oversight which might very readily occur during erection, and one case where tubes were eroded by water drained from stage heaters into the condenser. Except for these few cases leakage has been low.

Resistance of condensate as shown by Leeds & Northrup conductivity instrument has been consistently over 30,000 ohms at all loads. It is believed that a large proportion of the contamination of condensate is due to solids carried over from the boiler rather than to condenser leakage. One evidence of this is the fact that resistance of condensate is just as high or higher when the turbine is operating at light loads as when it is operating at full load, whereas if the contamination were due to any considerable amount of condenser leakage the reverse would be expected.

Up to the present time there have been no indications of serious deterioration of condenser tubes or of the rubber packing ring between tube sheet and condenser shell.

RATE OF DETERIORATION OF IMPREGNATED, WOOD-PULP CABLE PAPER SUBJECTED TO HEAT ONLY

INTRODUCTION

Research work for the Impregnated Paper Insulated Cable Research Subcommittee, on the effect of temperature on the rate of deterioration of cable paper insulation when not under dielectric stress, has been carried on at the Massachusetts Institute of Technology under Professor Bush since 1922. A complete report on an investigation of manila paper was published in the 1924 annual report of the N. E. L. A. Underground Systems Committee. A final report, which included some supplementary data, appeared in the *A. I. E. E. Journal* for May, 1925, and also in the general serial report of the N. E. L. A. Underground Systems Committee in 1927. A report of a similar investigation of wood-pulp paper insulation was also published in the above mentioned general serial report in 1927.

The results of the latter series of tests very clearly showed that a more extensive investigation of wood-pulp paper insulation should be made, with a larger number of samples over a longer period. A new series of tests was consequently started in 1926, and the complete final report (Report No. 3) was rendered by the Institute on March 15, 1928. This report covered about 25 typewritten pages and included over 150 sets of curves of results. A summary of those portions of the report dealing with test methods, equipment, preparation of specimens, etc., and a discussion of the results are presented in an appendix.

In the next section are given the conclusions which are drawn from the report of the tests made at the Institute.

COMMENTS ON RESULTS

Tests performed on wood-pulp paper, as used by representative American cable manufacturers, gave erratic results which were expected from previous tests of this type. The irregularity is evident in two ways: First, in the curves obtained from individual samples; second, in curves of different samples. The first irregularity is not as pronounced as it was in the first series of tests on wood-pulp paper, probably because the paper from which these samples were made was a more uniform product than the wood-pulp paper previously used (see Fig. 1). The variations between samples, as is shown by the table of distribution with respect to the average, is not very large.

The fact that many of the average curves show relatively small changes in the properties of the samples should not be construed to mean that such conditions actually hold for individual samples of paper as tested. Many of the individual samples show changes of large magnitude, which produce little effect on the average, due to the large numbers of samples.

The power factor curves are reasonably uniform except for occasional large changes of apparently accidental character, but no comparison with previous curves is possible because these are the first power factor curves obtained in the research.

20 Deg. Cent. Curves

The average of all samples at room temperature shows that large changes in the mechanical strengths do occur, even when the paper is not subjected to high temperature. In the average curves (Fig. 2) the paper recovered to almost its original value, but, nevertheless, it was at one time considerably below average. Among the individual curves certain samples give curves lying very definitely below the 100 per cent line after a lapse of time at room temperature and do not fully recover, as did the average sample.

50 Deg. Cent. and 70 Deg. Cent. Curves

The average curves at 50 deg. cent. and 70 deg. cent. (Fig. 3 and 4) show almost the same results as the 20 deg. cent. curves, except that folding endurance drops faster than tensile strength at 50 deg. cent. and 70 deg. cent., and vice versa at 20 deg. cent. A recovery period is present, and the paper regains almost its original state by the end of the test, at both temperatures.

90 Deg. Cent. and 100 Deg. Cent. Curves

The curves at 90 deg. cent., steady; 90 deg. cent., intermittent, and 100 deg. cent. (Fig. 5, 6 and 7) are quite similar to those obtained in the first series of tests at 80 deg. cent. and 90 deg. cent. and reported to the Cable Research Subcommittee on June 15, 1926. The principal exception is in the tearing strength, which in that test increased but here decreased.

At these temperatures definite deterioration occurs in all mechanical tests without recovery. The puncture voltage remains almost constant, as was found before.

Comparison Between 90 Deg. Cent., Steady, and 90 Deg. Cent., Intermittent

There is practically no difference between deterioration at a temperature of 90 deg. cent. continuously applied, or intermittently applied, according to the schedule described in the appendix (see page 10). In making this comparison it should be remembered that the 90 deg. cent. intermittent curves are plotted against calendar weeks and not against actual weeks at 90 deg. cent. The magnitude of the deterioration is slightly less in the intermittent test, but not enough less to conclude definitely that the difference was due to the recovery effects during the periods when the heat was shut off.

Publication No. 289-87. Serial Report, Underground Systems Committee.

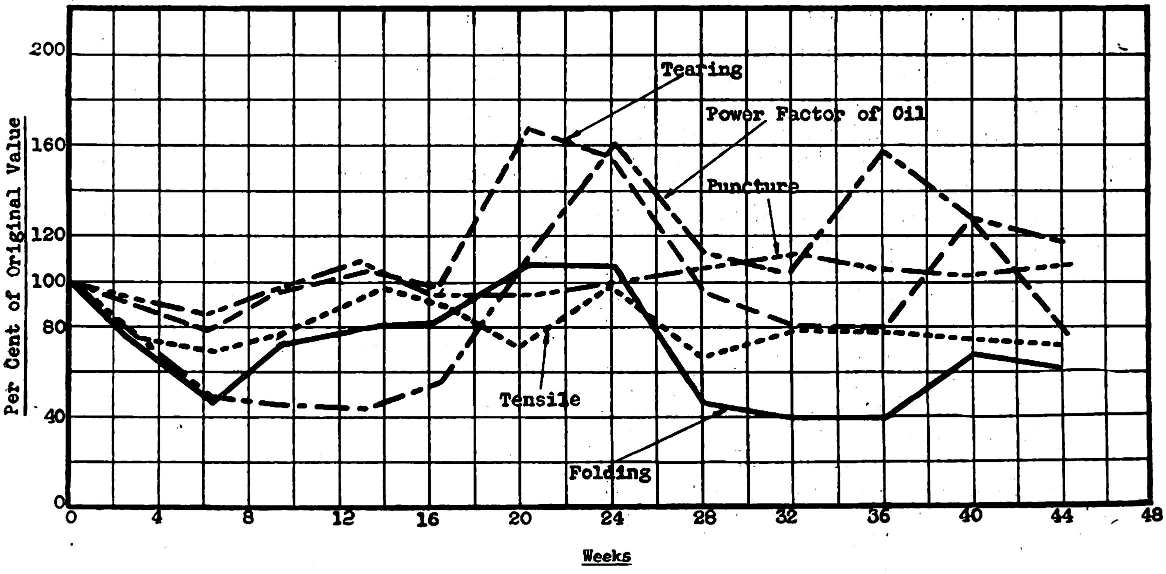

FIG. 1—TYPICAL SET OF CURVES FOR ONE SAMPLE AT ONE TEMPERATURE.

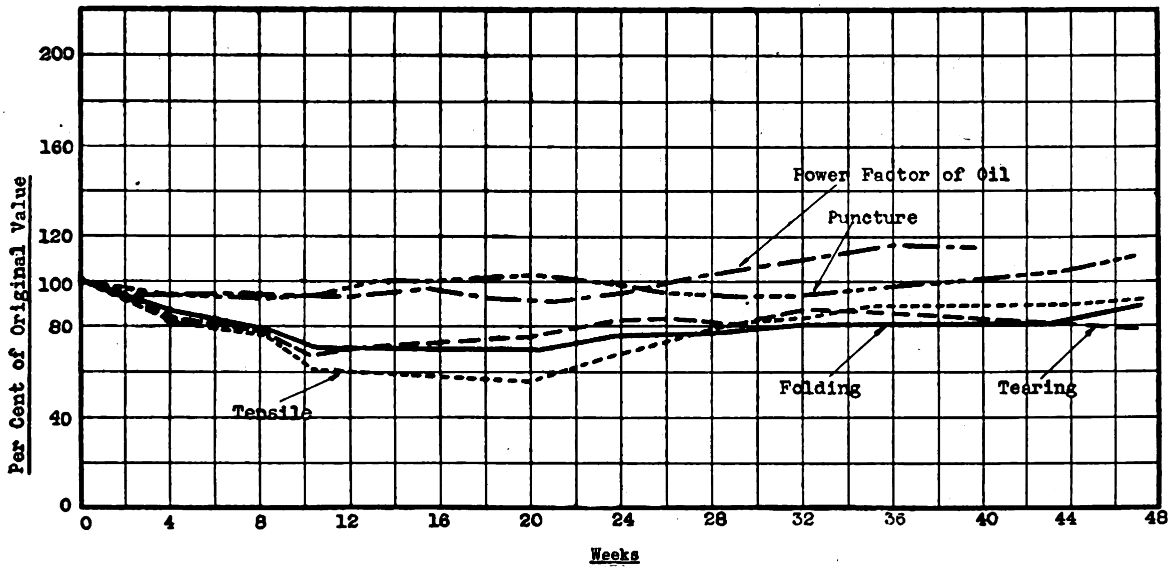

FIG. 2—AVERAGE OF ALL SAMPLES, 20 DEG. CENT.

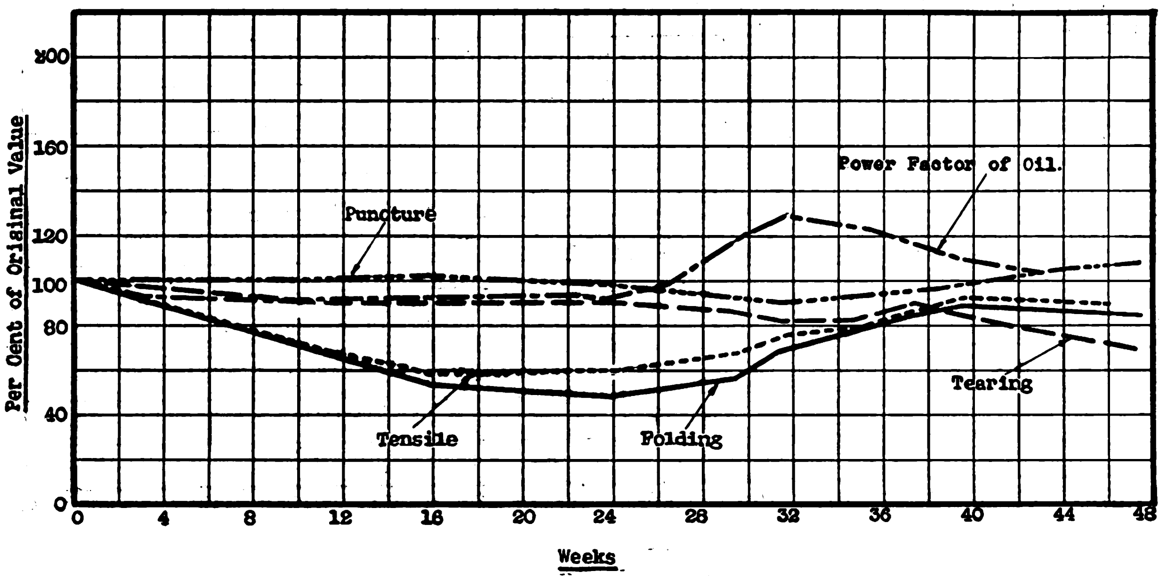

FIG. 3—AVERAGE OF ALL SAMPLES, 50 DEG. CENT.

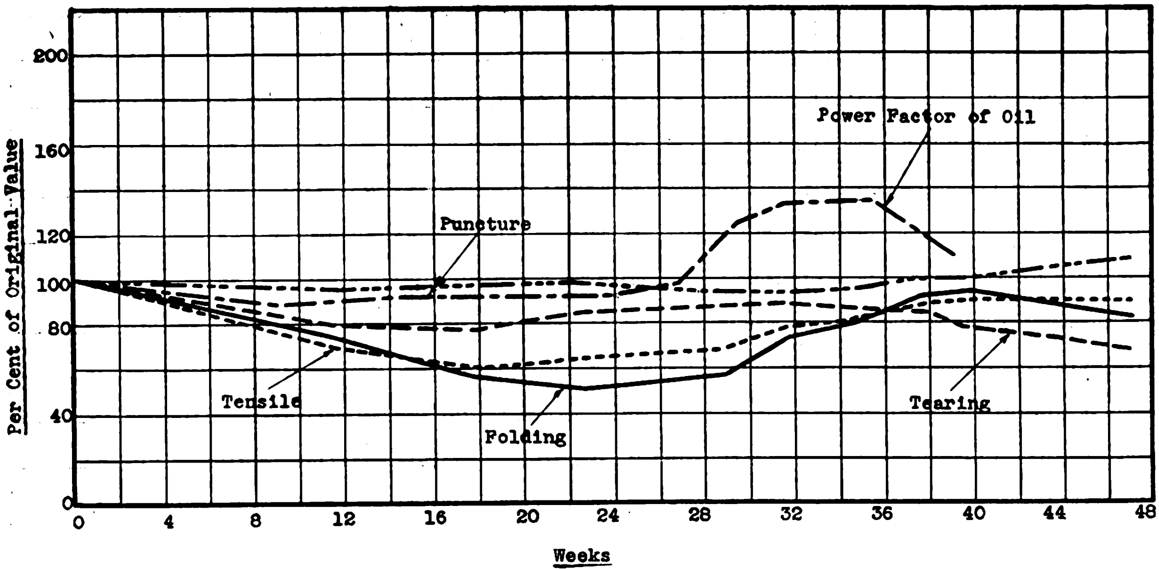

FIG. 4—AVERAGE OF ALL SAMPLES, 70 DEG. CENT.

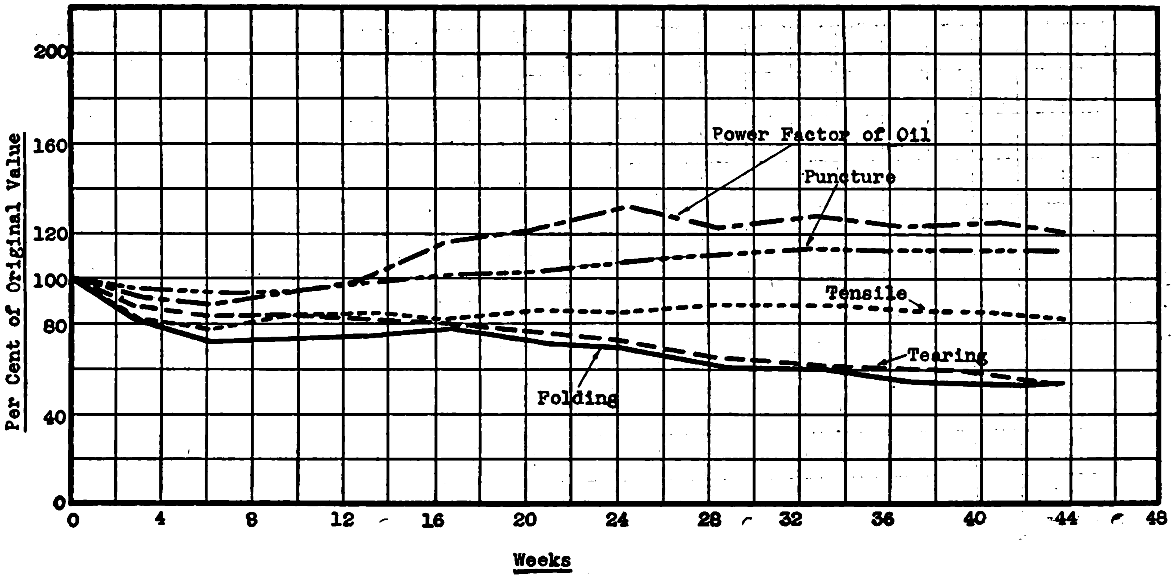

FIG. 5—AVERAGE OF ALL SAMPLES, 90 DEG. CENT. (CONTINUOUS).

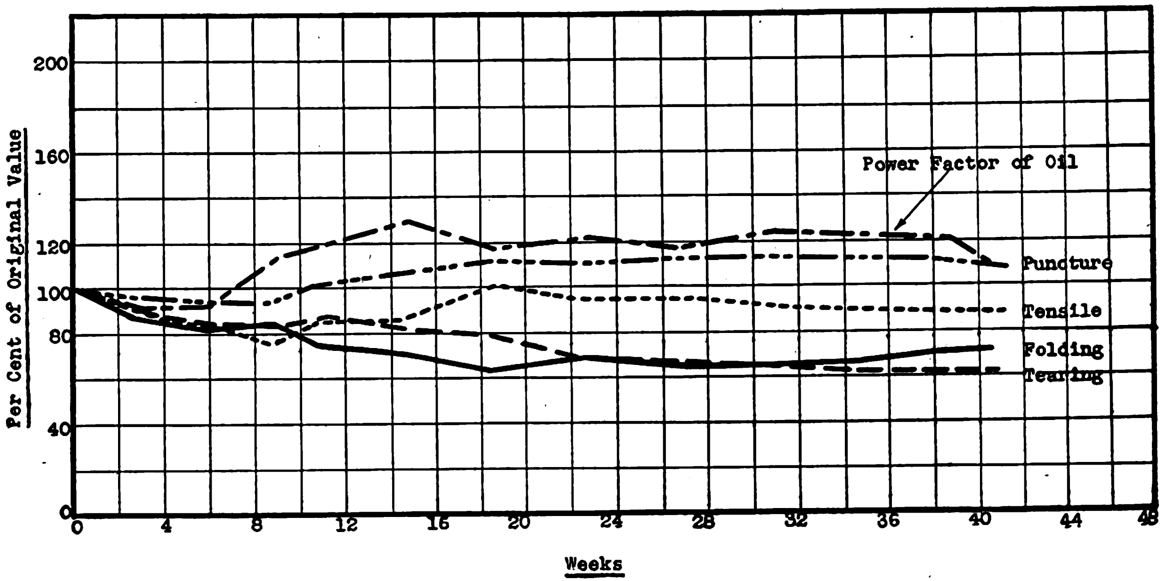

FIG. 6—AVERAGE OF ALL SAMPLES, 90 DEG. CENT. (INTERMITTENT).

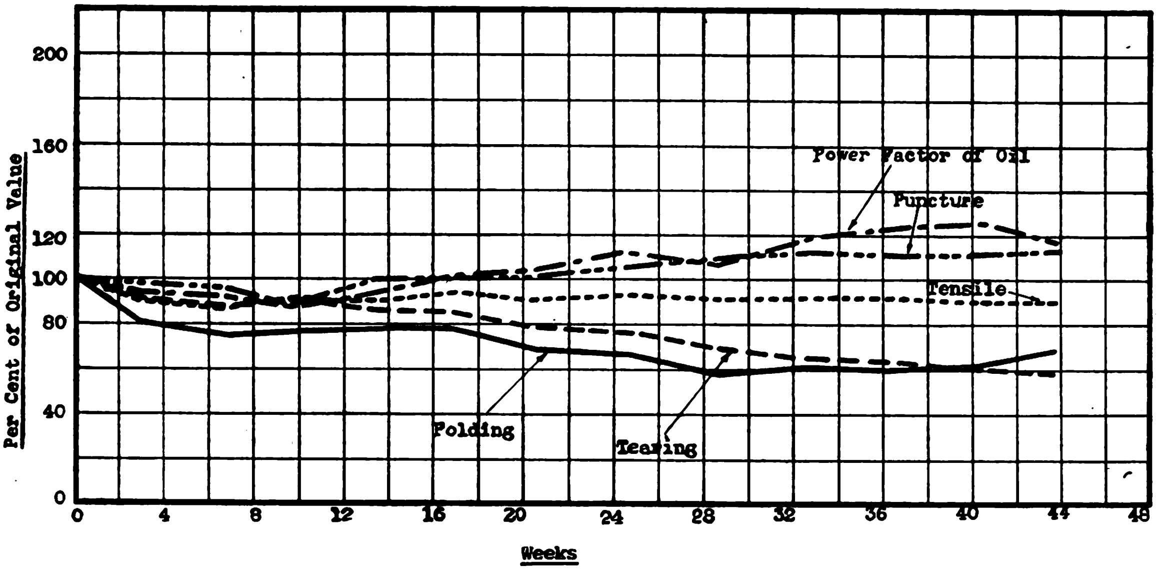

FIG. 7—AVERAGE OF ALL SAMPLES, 100 DEG. CENT.

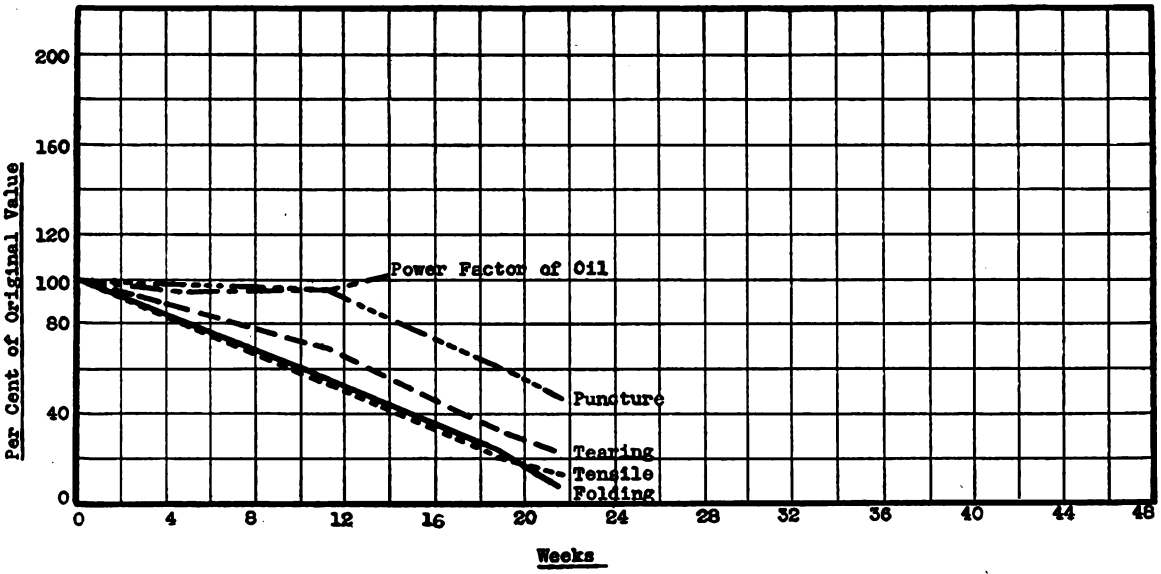

FIG. 8—AVERAGE OF ALL SAMPLES, 140 DEG. CENT.

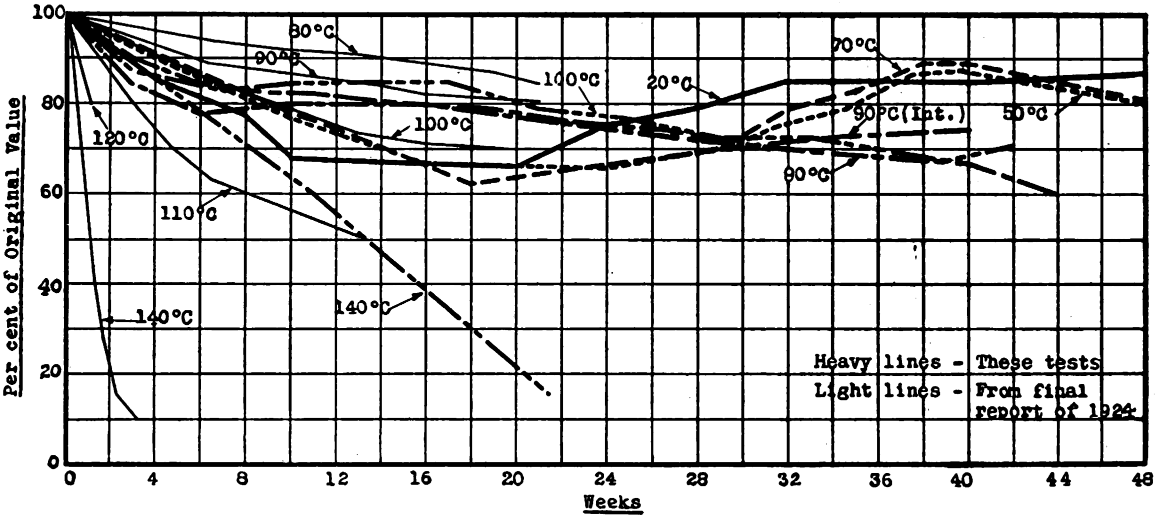

FIG. 9—GRAND AVERAGE, ALL MECHANICAL TESTS OF ALL WOOD-PULP PAPER SAMPLES.

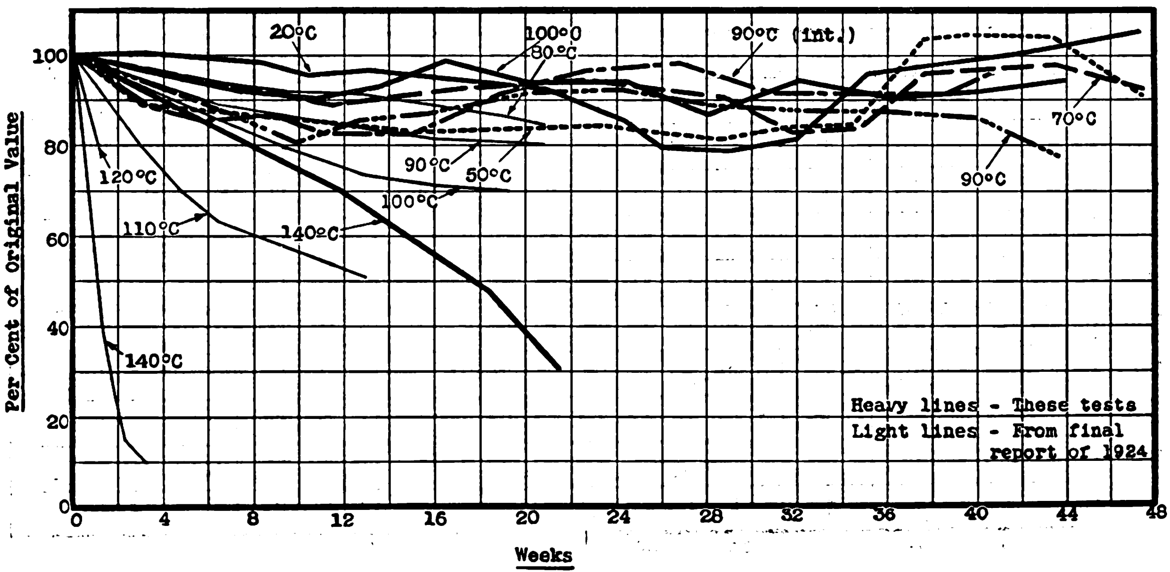

FIG. 10—GRAND AVERAGE, ALL MECHANICAL TESTS OF TWO MANILA SAMPLES ONLY.

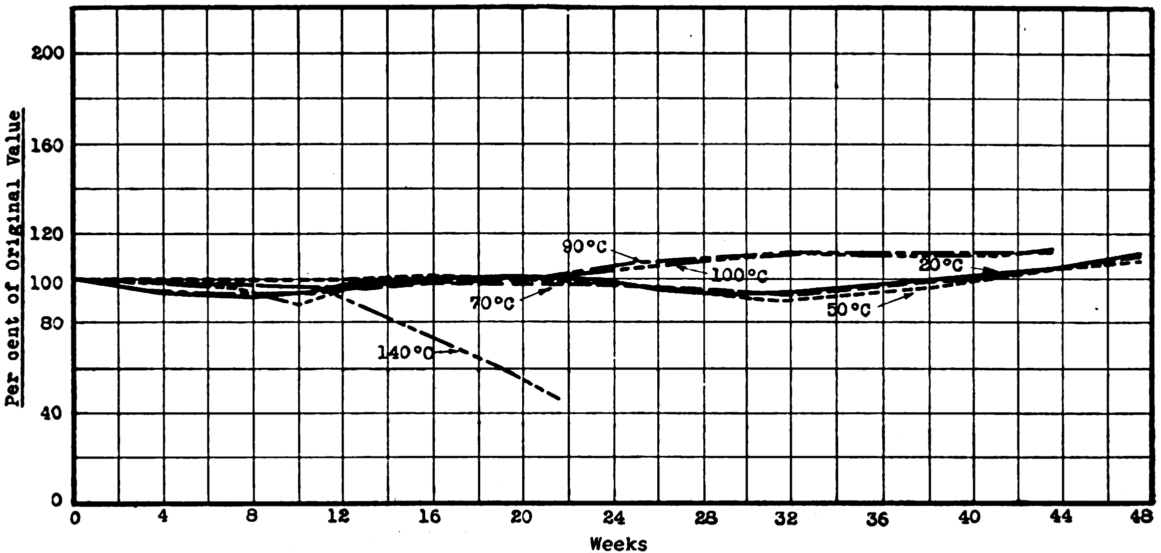

FIG. 11—AVERAGE DIELECTRIC STRENGTH, ALL SAMPLES.

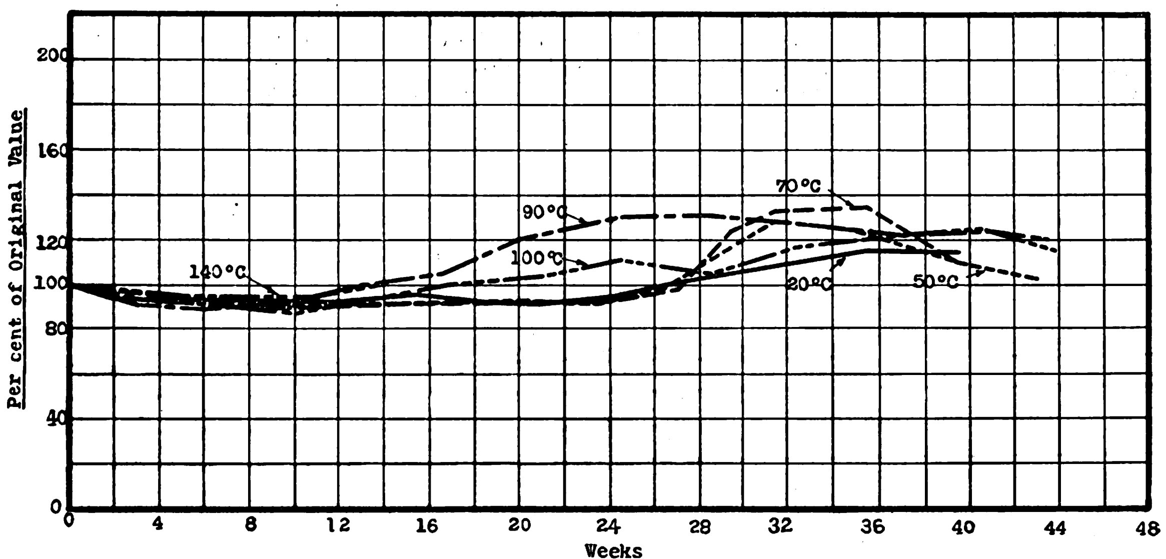

FIG. 12—AVERAGE POWER FACTOR, ALL SAMPLES.

The comparison is clearer when it is realized that in the 90 deg. cent intermittent curves, the samples were at a temperature of 90 deg. cent. for only about one-quarter the elapsed time. If only the time at maximum temperature were considered, the time scale would be one-quarter as great as it is plotted, and the curves compressed to that amount.

140 Deg. Cent. Curves

Mechanical deterioration (Fig. 8) is very rapid till complete destruction is reached, after a short time. Puncture voltage does not decrease as rapidly nor as completely.

Comparison Between 20 Deg. Cent., and 100 Deg. Cent.

The tests did not disclose any consistent or definite difference in the rate of deterioration as measused by mechanical tests for temperatures from 20 deg. cent. to 100 deg. cent. The puncture voltage is practically constant, with a tendency to increase rather than decrease.

Grand Average—All Mechanical Tests on Wood-Pulp Paper Samples

The combined average of all mechanical tests is given (Fig. 9) in comparison with the corresponding curves made on manila paper in 1924. These results are evident:

(a) The consistent change in trend referred to is conspicuous. The trend is fairly constant, downward, for a few weeks, and then at the lower temperatures (20 deg.-70 deg.) it is upward, to recover over one-half of the loss after 45 weeks. The 90 deg. cent. and 100 deg. cent. curves continued downward.

(b) Wood-pulp paper at temperatures up to 70 deg. cent. deteriorates faster than manila paper at 100 deg. cent. At 100 deg. cent. the wood-pulp paper does not deteriorate as rapidly as the manila paper. At 140 deg. cent. wood-pulp paper is very superior to manila paper.

(c) The 100 deg. cent. and 110 deg. cent. manila-paper curves might have shown a recovery or at least a flattening tendency if they had been extended for a longer time.

Grand Average—Mechanical Tests on Two Manila Samples

The general trend of the curves (Fig. 10) is similar to that of wood-pulp paper and much better than that obtained in the earlier test of 1924.

Dielectric Strength

These curves (Fig. 11) confirm the fact that dielectric strength is not affected by any temperature up to 100 deg. cent. and probably even higher.

Power Factor

The power factor tends to increase very gradually. (Fig. 12).

Summary

Summarizing the results as they are presented in Fig. 9, it is believed that the rate of deterioration of wood-pulp paper is no greater, after the first few months, than that of manila paper. The curves suggest that cable could be operated indefinitely at 100 deg. cent. so far as mechanical strength is concerned with only a loss of about 30 per cent. The flattening effect should, however, be confirmed by still longer tests which include manila paper. The very definite recovery characteristics at lower temperatures are worthy of further investigation as a special research problem.

It is the conclusion of the Committee that wood-pulp, properly treated, can be operated at as high temperatures and give as long life as manila paper.

APPENDIX

SUMMARY OF REPORT OF CABLE RESEARCH* AT THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY

Under the Direction of

PROF. VANNEVAR BUSH

Object of Research

This report covers the second series of tests conducted for the purpose of investigating, chiefly by mechanical examination, the rate of deterioriation of impregnated, wood-pulp paper, as used, at the time of starting the research, in cable insulation, when subjected to various constant temperatures in the absence of dielectric stress. It is the third report prepared for the Impregnated-Paper Insulated Cable Research Committee. The first report presented results obtained from tests made on manila hemp rope fiber paper and was dated June 20, 1924. The second report presented results of the first series of tests made on wood-pulp paper and was dated June 15, 1926.

Salaries and other operating expenses for this research have been defrayed by the National Electric Light Association and the Association of Edison Illuminating Companies. The Massachusetts Institute of Technology has furnished space, equipment and supervision. Test samples were, in this case, furnished entirely by the manufacturers associated with the Insulated Power Cable Engineers Association.

Test Methods, Equipment, Etc.

(a) Specimens Used

In previous tests the specimens used were pieces of actual cable cut from 6 to 8 in. long, with the ends sealed by soldering on tin can lids. There were a number of objections to this procedure.

It was an expensive method inasmuch as only a small portion of the paper was used while the copper and lead were sold at scrap value. The time of preparation per specimen was excessive. It was necessary to cut off each piece separately, shape each end of the specimen to fit the nearest size tin can lid, and then solder on the lid. It was not possible to do these operations in bulk by first cutting off all the samples of one size, then shaping all the ends and then sealing all the ends. This would have exposed the paper to the air for too long a time and vitiated the results. It was therefore necessary to complete the preparation of each specimen before beginning the next.

A third objection was the size and weight of the specimen in comparison to the portion of it useful for test purposes. Only a small portion of the paper was used in most cases, and this was obtainable only in short strips from a short length of cable. Moreover, it was often necessary to discard much of the paper on account of wrinkles.

The excessive bulk of the specimen was also objectionable from the standpoint of using the available oven volume to the greatest extent. The five ovens used could hold about 500 specimens. It was found possible to increase this capacity to about 2000 specimens by changing their form.

The uniform specimen used in all the tests covered by this report, was designed to meet the above objections without destroying the value of the specimen as an index of the behavior of the paper in actual cable under the conditions of the test. The specimens were simply rolls of paper tape representing the paper to be investigated, wound on copper cores and then impregnated by standard processes. The required number of specimens of each of the various samples of paper were prepared by the cable manufacturers according to very detailed instructions which were given them. All of the cable manufacturers cooperated in preparing and furnishing these specimens.

Fig. 13 shows the appearance of the standard specimen before being impregnated. The spindle on which the paper is wound is of copper and is 1 in. in diameter. The paper tape is 1 in. wide, and is wound on the spindle under approximately the same tension as the manufacturer normally uses for cable. After winding, the roll of paper is tied with strong thread and slipped into the can. It is separated from the bottom of the can by a circular piece of cardboard, and held in place by a piece of cardboard bent into a V, with the apex resting on the sample, and the two ends caught under the rim at the top of the can.

After the mechanical preparation of the specimens, they were impregnated in position in the cans, and then the tops sealed on the cans. The standard procedure was to treat these specimens in the impregnating process as if they were actual cable, and to seal them immediately by pressing on the lids. The lids of the cans were made oversize and had to be forced into place, making a seal which was airtight

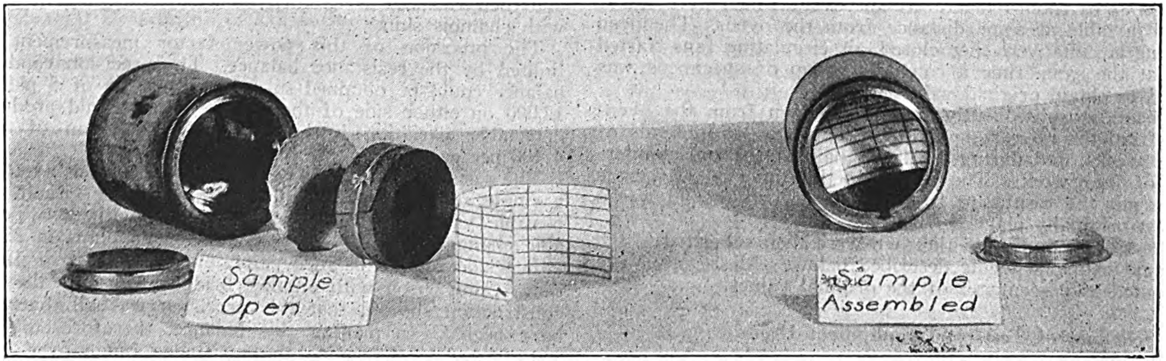

FIG. 13—STANDARD SPECIMEN BEFORE IMPREGNATION.

---

* Report No. 3, March 15, 1928.

at atmospheric pressure. The samples thus prepared were then shipped to the Massachusetts Institute of Technology, where the lids were soldered on, using resin as a flux, and a soldering iron rather than a flame, to prevent damage to the specimens. Although pure resin was used as a soldering flux, a number of specimens were tested before and after soldering with an acid paste, to detect the presence of hydrogen ions inside the can. No hydrogen ion concentration could be detected, even near the joint between lid and can. The same test was made on some empty cans to see that no acid traces were left by the manufacturer of the cans. This test indicated that the cans supplied were neutral.

It was intended to have all the specimens made from paper of nominal 5 mil thickness, but this imposed too great a restriction on the manufacturers who supplied the paper, and the plan was abandoned.

This type of specimen had an additional advantage over the former type in that it could be opened with a can opener to extract the paper. Formerly, a shaper was used to split the lead sheath, in order to cut to uniform depth and not damage the paper immediately under the sheath too much.

A total of 22 kinds of paper was submitted. Of these 18 were wood-pulp, and 2 manila and wood-pulp combined. Two manila paper samples were included as a check on the previous work on manila paper.

(b) General Procedure

The specimens were held at the following constant temperatures during the course of these tests: 20 deg. cent. (room temperature), 50 deg. cent., 70 deg. cent., 90 deg. cent. and 140 deg. cent. In addition, an intermittent temperature run was made with the temperature varying between approximately 50 deg. cent. and 90 deg. cent., according to a definite schedule, as follows:

The heating circuit was closed every week-day morning at 9 o'clock. The maximum temperature was reached at about 10:30 a. m., where it was held until 4:30 p. m., at which time the heating circuit was shut off. The minimum temperature was reached at about 8 p. m. On Saturdays this oven was shut down at 1 p. m. and remained off until the following Monday morning. The minimum temperature obtainable was determined by the conduction of heat through the walls from the adjoining oven.

In preparing the oven used for the test at 50 deg. cent., it was found that heat conduction from the other ovens was sufficient to keep the average temperature above 50 deg. cent. Accordingly, air at 35 deg. cent. was admitted to the oven by means of a pipe, from the small room which contained the ovens. The electric heating coils and temperature controls could then be used to maintain 50 deg. cent.

The temperature controls were adjusted, with the ovens empty, to give the desired average temperature. The settings of the temperature controls were adjusted by means of calibrated thermocouples located in each oven, disregarding the temperature scale furnished with the controls, except as a means of recording the constancy of temperature.

The specimens were then stacked in the ovens, except for the group of room temperature specimens which were placed under a table at some distance from the ovens. The oven heating circuits were then closed, air circulating fans started and at the same time a complete group of specimens was tested to obtain original values.

Specimens subsequently were withdrawn from the ovens and from the room temperature group, first at intervals of three weeks, and during the latter half of the run at intervals of four weeks. The change in time interval was made to permit the results to be extended beyond the 40 weeks of test originally planned.

The specimens thus withdrawn were then subjected to the regular testing schedule described below. All results were computed as percentages of the original values.

(c) Schedule of Tests and Equipment Used

The tests made on these specimens were, in general, the same as those made on the previous series of woodpulp paper tests, with the addition of a power factor test made on the excess oil contained in the tin cans, and a slight change in making the voltage puncture tests.

1. *Folding endurance*—Ten tests per specimen on strips one centimeter in width, made under a tension of 0.75 kilogram, on the Institute Folding Endurance Tester.
2. *Tensile strength*—Ten tests per specimen made on a standard Schopper tensile machine. The full width of the sample was used in each case.
3. *Tearing strength*—Five tests per specimen using four strips per test, made on the Elmendorf tearing machine.
4. *Puncture voltage*—Ten tests per specimen between brass electrodes, one centimeter in diameter. Previous to these tests a single pair of electrodes had been used, between which one piece of paper at a time was placed and broken down. In order to save time on this test, a group of ten pairs of electrodes was built, which could accommodate all the strips from one specimen at one time. The high voltage was then applied successively to each pair of electrodes, using a motor-driven rheostat in the field circuit of the supply alternator to insure the same rate of change of applied voltage for each test strip. This method took only about half the time previously required.
5. *Power factor of oil*—One test per specimen made between brass plates, machined flat, 4 in. in diameter, and spaced 0.009 in. apart, the measurements being made on a General Radio capacity bridge (Wien type) using a 1000-cycle tuning fork oscillator at the source of supply. The constants of the apparatus were combined in a calibration curve, which facilitated the computation of the power factor for a large number of specimens.

This equipment was installed in the eighth week of testing. The group of room temperature specimens withdrawn for test at that time was used to provide "original" values. It will be noticed in the curves at 20, 50, 70 and 140 deg. cent. that the power factor curves do not extend as far as the others due to the lag in starting the test. The runs at 90 deg. cent., steady, 90 deg. cent., intermittent, and 100 deg. cent. were started much later than the others, so that the power factor tests at these temperatures are coincident with the other tests.

The procedure was to fill the space between the plates with compound taken from the can under test. All air pockets were worked out of the space as far as possible, and the spacing between plates adjusted. The variation in power factor caused by air caught between the plates was found to be negligible. The measurement of the power factor was accomplished by using the method of substitution to determine the capacitance and equivalent series resistance of the cell containing the oil. The capacitance was determined directly from the difference in the readings of a precision condenser necessary to balance the bridge, without and with the power factor cell in parallel respectively. The resistance balance was obtained by means of a decade resistance box in the other variable arm of the bridge.

A calibration curve was drawn which permitted the computation of the desired power factor directly as the product of the decade box reading and a constant obtained from the calibration curve, this constant being a function of the difference in the readings of the precision condenser.

After each power factor measurement the cell was emptied and then cleaned, using ether as a solvent and wiping dry with chamois skin.

The precision of this power factor measurement was limited by the resistance balance. The precision condenser balance could be obtained so that a variation of 5 parts in 12,000 on either side of the balance point would produce a detectable variation in balance, or a precision of about 4/100 per cent.

The resistance balance was very poor, however, even with a single stage audio amplifier in the detector circuit. The possible variation in resistance readings without a detectable change in balance was as high as 25 ohms in 250 on either side of the balance point, or a precision of 10 per cent. Comparison with another bridge of exactly the same construction showed that this precision was all that could be expected. In making this balance, therefore, the procedure was to determine the resistance range over which the balance was apparently constant, and then take the midpoint between the two extremes as the reading. This error is not important, however, because the experimental variations in power factor were large compared to the amount of error.

All tests, except those of puncture voltage, were made in the specially constructed low humidity room as described in preceding reports. Briefly, it consisted of a small room completely enclosed in thick, moisture-proof walls. Entrance was made through a thick door built similar to a refrigerator door. Outside the room a large tank containing anhydrous calcium chloride was set up, through which the air of the room was continually circulated, removing the moisture. Inside the room an automobile radiator was mounted, through which cold water was constantly circulated. The purpose of this was to maintain a fairly constant low temperature in the room and prevent perspiration from the test man from increasing the humidity. The measurement of humidity was made by means of an ordinary sling psychrometer, mounted vertically and using a small fan to obtain the required circulation about the wet and dry bulbs.

The puncture voltage tests were made in the high-voltage laboratory where the humidity could not be controlled. Tests made on these samples, however, showed that no appreciable change of puncture voltage occurred even when the samples were exposed to the air until saturated.

(d) Number of Tests Made

Number of samples:	
Wood-pulp paper	18
Manila paper	2
Wood-pulp and manila	2
Total	22
Number of specimens per temperature	330
Number of temperatures	7
Total number of specimens	2,310
Number of individual tests per specimen	36
Total number of individual tests scheduled to be made	83,160
Reduction for specimens not used in 140 deg. cent. test	2,370
Net total of tests made	80,790

Comparing this figure with the total of tests covered by the preceding report (23,600—final report of June 15, 1926, on manila paper), a ratio of approximately 3.5 is obtained. This ratio is low, in view of the increased capacity of the ovens from using the specially prepared specimens. The previous figure, however, included a large number of tests made to determine the effect of humidity on the mechanical properties of the paper. Tests made to determine the effect of moisture absorbed by the paper tested at this time were not included in the above number, although the number is about 3300.

Discussion of Results

(a) General Description of Curve Sheets

A total of 152 curve sheets are included in the complete report but only one, a reasonably typical one, is reproduced here (Fig. 1) as an example. These curve sheets showed the results of tests made on the individual samples at the various test temperatures. The curves are plotted as percentages of original value (ordinates) against time of heating in weeks (abscissæ). Seven curves are included for each sample of paper tested, corresponding to temperatures of 20 deg. cent., 50 deg. cent., 70 deg. cent., 90 deg. cent., 90 deg. cent. intermittent, 100 deg. cent. and 140 deg. cent. respectively. The temperature is shown on each curve sheet as part of the horizontal scale marking, i.e., "Weeks at —— deg. cent." On each sheet the legend at the lower right-hand corner contains the serial number of the curve, the code letter of the sample, the original values of the tests made for each sample, and the identification of the lines used in plotting the results of the various tests made.

(b) Curves of Individual Samples

As in the previous results obtained from tests of this type, the most noticeable characteristic is the erratic course of the curves. Fig. 1 is reasonably typical—some of the curves were much more erratic and some less erratic. Broken line plots are drawn in all cases, although the characteristics could be represented by smooth curves in some cases.

From glancing through the curve sheets corresponding to any particular temperature, it is apparent that some grouping of samples is possible. Using the complete curves contained in this report, it will be possible to draw comparisons of this nature.

The distribution of the samples relative to the average results obtained can be found, approximately, by superposing the average curves on each set of individual curves, using the average curve at the same temperature as the individual curve in each case. Having thus superposed the curves, we can note whether the characteristics of the individual curve under consideration lie, in general, above, below or along the average curves.

This has been done, using only the tests which were made on the paper in estimating the relative positions of the various curves. The power factor curves were excluded because the results of the tests on the paper are those primarily wanted and also because the large variations in the power factor (which will be discussed later) made it possible to completely reverse the normal classification based on paper tests only.

The tabulation given below shows the results of such an examination at each temperature, based on a total of 22 samples and therefore including the two manila paper samples. The figures are, of course, only approximate.

TABLE I

DISTRIBUTION WITH RESPECT TO THE AVERAGE

Temperature Deg. cent.	Number of Avg. Samples Per cent	Number of Samples Above Avg. Per cent	Number of Samples Below Avg. Per cent
20	55	22½	22½
50	50	27	23
70	55	22½	22½
90 (steady)	50	30	20
90 (intermittent)	50	27	23
100	50	27	23
140	75	10	15

This tabulation does not take into account the absolute values obtained in the various tests made on the paper, but only the deterioration expressed as a percentage of original value. Similar tabulations may be prepared showing the distribution with respect to any particular kind of test, using either absolute values or relative deterioration.

Most of the samples had the same classification at each temperature up to 100 deg. cent., although a few changes did occur. The manila paper samples, incidentally, were in almost every case classified as *above* average.

Referring to the tabulation given, it will be seen that for temperatures up to 100 deg. cent., a little more than half the samples show average characteristics. The remaining samples are divided with slightly more below average than above. The number, however, above average includes the manila paper samples. If these were discarded in getting the distribution, we should get about 60 per cent average, 25 per cent below average and 15 per cent above average. The distribution at 140 deg. cent. is largely grouped near the average; in fact, only one or two samples show any tendency to depart from the average to a large extent.

It is apparent from these considerations that the average curves are not derived from widely divergent values, in general, but from individual characteristics, the majority of which are grouped near the average. It should be noted here that samples classified as above or below average are in most cases slightly above or below average, and do not contribute widely divergent data toward the final result.

The individual curves of power factor (of oil) show a number of cases where sudden temporary increases of power factor occurred, and also a number of cases where the power factor curve as a whole increased considerably, and went off the curve sheet altogether. In these latter cases the value of the ordinate off the sheet is printed at the top of the abscissa to which it applies.

In the case where the power factor curve shows a sudden increase and then a decrease, it is undoubtedly an accidental change, and the point should be treated as doubtful. With a spacing of only 0.009 in. between the plates in the measuring cell, small foreign particles were very apt to cause such discrepancies. Usually such readings were not noticed until the data were plotted and then it was too late to make another test. The test routine did not permit the time necessary to check each test, as it was made, against the previous results. Also, there were many large increases in power factor of a legitimate nature, and it would be futile to attempt to distinguish the good and the poor readings as they were obtained. These apparently accidental high readings are included in the curves as a matter of record.

(c) Average Curves

Fig. 2 to 8 inclusive show the results of averaging all samples, for each kind of test, at temperatures of 20 deg. cent., 50 deg. cent., 70 deg. cent., 90 deg. cent., 90 deg. cent. (intermittent), 100 deg. cent. and 140 deg. cent. respectively. In addition, these curves are partly smoothed by plotting each point as the average of the true ordinate at that time, and the true ordinates immediately before and after the time under consideration.

With the exception of the 20 deg. cent. series the folding endurance test shows the greatest tendency to change, of all the tests. In the 20 deg. cent. series the tensile strength decreases more than folding endurance, but recovers and finishes at the 47th week slightly greater than the folding endurance. In the 140 deg. cent. series, the tensile strength and folding endurance curves are almost coincident.

For purposes of comparison, the average curves can be divided into four groupings according to temperature, as follows: Group I—20 deg. cent. curves only; Group II—50 deg. cent. and 70 deg. cent. curves; Group III—90 deg. cent., 90 deg. cent. (intermittent), and 100 deg. cent. curves; Group IV—140 deg. cent. curves only. (See also Fig. 9.)

1. *Group I, 20 deg. cent.* The greatest change was found in the tensile strength, which decreased to 55 per cent at the 20th week, and then recovered, reaching 92 per cent at the 47th week. Folding endurance and tearing strength went very closely together, reaching minimum values of 70 per cent and 67 per cent respectively, and recovering to 89 per cent and 79 per cent respectively at the 47th week. Puncture voltage decreased to 92 per cent at the 8th week, increased to 102 per cent at the 20th week, decreased to 93 per cent at the 29th week, and increased to 112 per cent at the 47th week. On the average, the puncture voltage was practically constant at room temperature. The power factor of the oil decreased at first, reaching 91 per cent, at the 21st week, but increased to 115 per cent at the 39th week, and was again sloping slightly downward at that time.

2. *Group II,* 50 *deg. cent. and* 70 *deg. cent.* The folding endurance curves at both temperatures are almost coincident, with the minimum of 50 per cent at the 23rd week and a final value of 84 per cent at the 47th week. The tensile strength curves are also very close together, reaching 60 per cent at the 17th week and having a final value of 90 per cent at the 47th week. The puncture voltage curves are similar at both temperatures, and both reach 110 per cent at the 47th week from a minimum of about 92 per cent at the 32nd week. The power factor curves in both cases remain practically constant at about 90 per cent between the 10th and 25th weeks. They then increase to about 130 per cent at the 32nd week and decrease to 110 per cent at the 39th week. This part of the curve is undoubtedly incorrect, and was probably caused by incorrect spacing of the plates between which the test was made, at the 32nd week. The correct power factor curve is almost a constant upward slope from about 92 per cent at the 24th week to about 110 per cent at the 40th week.

3. *Group III,* 90 *deg. cent. and* 100 *deg. cent.* The curves are characterized by general slopes in one direction, without the recovery phenomena found in the two preceding groups. The folding endurance decreases in the first 6 weeks to points between 70 per cent and 80 per cent. The slope then changes, so that at the 36th week the group average is about 60 per cent folding endurance. This is a decrease of slope from 4 per cent per week to about 0.5 per cent per week. The tensile strength has a slight tendency to show a recovery period in both the 90 deg. cent. tests, but at 100 deg. cent., its slope is generally downward. The 36th week value of tensile strength for the whole group, however, is about 90 per cent. The tearing strength at all three temperatures reached about the same point as folding endurance at the 36th week, namely, 60 per cent, but it showed a fairly constant average slope throughout. The puncture voltage decreased slightly for the first ten weeks at a rate less than 1 per cent per week, and then increased at a nearly constant rate, reaching a group average of 112 per cent at the 36th week. The power factor curve shows a decrease in the first 6 weeks on both 90 deg. cent. sheets to about 90 per cent, and then increases to a final value of 122 per cent at the 36th week. Slight irregularities in the power factor curves occur similar to those found in Group II, but not as pronounced. The power factor at 100 deg. cent. decreases for the first 10 weeks to 86 per cent and then increases to 122 per cent at the 36th week, which is the same as the two 90 deg. cent. values at that time.

4. *Group IV,* 140 *deg. cent.* Both folding endurance and tensile strength decrease together at a constant rate, reaching a value of only 10 per cent at the 22nd week, when the test ended. The tearing strength decreased more slowly, reaching about 20 per cent at the 22nd week. The puncture voltage was almost constant for the first 11 weeks at 100 per cent, but dropped from there to 45 per cent in the last 11 weeks. The power factor test remained constant for the first 11 weeks and then started to go up, but due to its late start went only to the 14th week. Too short a time is involved in this curve to make it a reliable indication of the behavior of power factor at 140 deg. cent.

CUSTOMER OWNERSHIP COMMITTEE

Data collected under the direction of the Customer Ownership Committee of the N. E. L. A. for the year 1928 show a marked decrease in this form of financing compared with the five preceding years. Although five companies were added to those reporting, having engaged in customer ownership activities, or a total of 251, the total number of new shareholders added and the number of shares sold, were considerably less than in 1927. For 1928 apparently 202,380 new shareholders were obtained compared with 249,491 in 1927; shares sold in 1928 were 2,081,071 compared with 3,581,206 in 1927.

The total number of home shareholders added by the customer ownership plan by the companies reporting was computed to be 1,884,148, as of Dec. 31, 1928.

Decreasing activities during 1928 were anticipated, and it is believed do not indicate any real loss of interest in customer ownership on the part of electric light and power companies. The results for the year seem merely to reflect the general conditions bearing upon the financing of capital requirements. These requirements to a larger degree than formerly were supplied by the sale of common stock. The popularity of electric light and power securities in general (to which customer ownership activities in past years contributed in no small degree) with the increasing demand of the investing public for common stock investments, brought about a period which dictated the wisdom of a larger proportion of financing by means of common stock issues. This period followed one whereby a large part of financing requirements were most advantageously handled by bond issues. Because of these facts it was inevitable that the amount of preferred stocks which could be issued, and at the same time preserve well-balanced financial structures (enabling the ingress of capital on the lowest average terms) was curtailed. Inasmuch as the majority of companies have maintained a policy of restricting customer ownership distribution to preferred stock, the effect upon this particular form of financing is obvious.

Many companies which were formerly active in customer ownership distribution and which are firmly committed to the policy as most desirable, were compelled to cease temporarily the sale of preferred stock in 1927 and to a greater extent in 1928, principally for the reasons cited. Managements usually have regretted the necessity of such a course and have studied ways and means to maintain customer ownership distribution continuously. Thus far, however, no generally accepted plan has been developed, insofar as the committee knows, which solves the problem. It seems fair to assume that the conditions militating against building up the number of home shareholders in many localities will eventually correct themselves and resumption of activities by companies forced to discontinue may be confidently expected.

The year 1928 witnessed a general trend toward lower rates of dividends on the preferred stocks issued and sold, the rate in some instances being as low as 5½ per cent.

Your committee continued to support the plan of cooperation with the National Better Business Bureau, toward the protection of the holdings of shareholders, which was fully described in last year's report. The following letter was sent to member companies over the signature of the chairman:

> "The Customer Ownership Committee has directed me, as Chairman, to call your attention to the 1928 Convention report of the Committee and the plan outlined and recommended for cooperation with the National Better Business Bureau.
>
> "This plan aims to offer a specific service toward the protection of the holdings of customer-shareholders. The National Better Business Bureau is an established institution of high reputation, with a responsible Board of Directors. It is devoted to the suppression of fraud, misrepresentation and questionable methods applied to the exploitation of the public, and has a successful record.
>
> "Your Committee recommends that you seriously consider the service which the Bureau offers and determine the value of such services to your organization. Necessarily, the annual financial subscription which your company may make to the Bureau must be a matter of mutual negotiation.
>
> "The officers of the National Better Business Bureau will communicate with you direct, and it is hoped that you will give them opportunity to fully present their proposal."

March 6, 1929, the chairman reported to the Public Relations National Section that the response of member companies, in the way of subscriptions to the National Better Business Bureau, was not considered satisfactory, and offered a resolution, which was adopted, the substance of which was as follows:

> "Attention is further directed to the importance of protecting utility stockholders through the National Better Business Bureau, and also to the desirability of utilizing the services of that Bureau toward preventing abuse of Customer Ownership principles by irresponsible companies and persons controlling a limited number of utility properties.
>
> "The chairman therefore recommends that the foregoing be brought before the executive committee of the National Electric Light Association with the request that the executive committee take suitable action to urge Member Companies, and particularly holding companies of a national or semi-national character, to extend a suitable measure of financial support to the National Better Business Bureau."

This resolution was endorsed by the Executive Committee, and in April, 1929, was approved by the Public Policy Committee.

Under date of April 20, 1929, the general manager of the National Better Business Bureau submitted a compilation of the amounts contributed by electric light and power companies, both to that body and to the local Better Business Bureaus. This showed the following:

Publication No. 289-78, Serial Report.

Annual subscription to National Better Business Bureau	$6,800
Special subscription to National Better Business Bureau	1,000
Total to National Better Business Bureau	$7,800
Annual subscription to local Better Business Bureau	6,915
Total	$14,715

The companies subscribing to the National Better Business Bureau were as follows:

Byllesby Engineering & Management Corporation.
Brooklyn Borough Gas Company.
Brooklyn Edison Company.
Columbia Gas & Electric Company.
Commonwealth Edison Company.
Consolidated Gas Company of New York.
H. L. Doherty & Company.
Detroit Edison Company.
Eastern Connecticut Power Company.
Georgia Power Company.
International Utilities Corporation.
Middle West Utilities Company.
Midland Utilities Company.
Pennsylvania-Ohio Electric Company.
Pennsylvania Water & Power Company.
Peoples Gas Light & Coke Company.
Portland (Ore.) Electric Power Company.
Public Service Corp. of Northern Illinois.
Public Service Corp. of New Jersey.
San Antonio Public Service Company.
Standard Gas & Electric Company.
United Companies.
Central Maine Power Company.
New England Public Service Company.
National Electric Power Company.
Utilities Securities Company.

There are 42 local Better Business Bureaus in the United States and one in Canada. Of these it was found that companies were contributing annual amounts to 31 local bureaus, were not contributing to 5, while 7 bureaus had not reported.

The companies listed as contributing to local bureaus were as follows:

Akron, Ohio, Northern Ohio Power & Light Company.
Baltimore, Md., Consolidated Gas, Electric Light & Power Company of Baltimore.
Chicago, Ill., Commonwealth Edison Company.
Cincinnati, Ohio, Union Gas & Electric Company.
Detroit, Mich., Detroit Edison Company; Consolidated Power Company (Jackson, Mich.).
Fort Wayne, Ind., Indiana Service Corporation.
Hartford, Conn., Hartford Electric Light Company.
Indianapolis, Ind., Indianapolis Power & Light Company.
Lima, Ohio, Ohio Power Company.
Providence, R. I., Narragansett Electric Light Company.
Scranton, Pa., Scranton Electric Company.
Utica, N. Y., Utica Gas & Electric Company.
Kansas City, Mo., Kansas City Power & Light Company.
Cleveland, Ohio, Cleveland Electric Illuminating Company.
Toledo, Ohio, Toledo Edison Company.
Dayton, Ohio, Dayton Power & Light Company.
Philadelphia, Pa., Philadelphia Electric Company.
Boston, Mass., Edison Electric Illuminating Company; Gas & Electric Improvement Company; Malden Electric Company.
Portland, Ore., Portland Electric Power Company.
Stockton, Cal., Western States Gas & Electric Company (controlled by Pacific Gas & Elec. Co.).
Tacoma, Wash., Tacoma Railway & Traction Company.
Dallas, Tex., Dallas Power & Light Company.
Peoria, Ill., Illinois Light & Power Company; Central Illinois Light Company.
San Diego, Cal., San Diego Cons. Gas & Electric Company.
Seattle, Wash., Puget Sound Power & Light Company.
Oakland, Cal., Pacific Gas & Electric Company; Great Western Power Company.
Canton, Ohio, Ohio Power Company.
Birmingham, Ala., Birmingham Electric Company.
Long Beach, Cal., Southern California Edison Company.
Rochester, N. Y., Rochester Gas & Electric Corp.
Houston, Tex., Houston Lighting & Power Company.

Among the bureaus not reporting is that at Louisville, Ky., to which the Louisville Gas & Electric Company is a subscriber.

Confusion has existed in the past as to subscriptions as between the national and local bureaus. Toward clarification the general manager of the National Better Business Bureau submitted the following:

> "It is my opinion that most of the public utility companies are making a fair pro rata subscription to the income of the local Better Business Bureaus. Some of them, however, could be increased, thereby materially aiding the program in the financial field in which the local bureaus are engaged. Of course, those bureaus not now receiving support should be accorded consideration as soon as possible.
>
> "In a Better Business Bureau executive conference held in St. Louis it was decided that the operating companies located in local bureau communities should subscribe directly to the local Better Business Bureaus, while those outside those vicinities should subscribe to the National Better Business Bureau. This plan may modify our present arrangement, but we believe that it will effect efficiency in operation and simplicity in obtaining subscriptions."

Your committee renews its recommendations that careful consideration be given to effective cooperation with both national and local Better Business Bureaus, that this work be financially supported, and that the whole question of helping shareholders safeguard their investments be constantly studied in order to render the most effective and practical assistance.

During the year a case (Murphy v. the Wyandotte County Gas Company), involving customer ownership, was decided by Judge Pollock in the United States Court, Kansas District First Division. This decision was in favor of the company, and the opinion discusses customer ownership in a most interesting manner. It is one of few, if it is not the only, legal action involving customer ownership principles and activities, and the opinion is incorporated as part of this report, as Appendix A.

Your Committee submits the customary statistical reports, and desires to express its appreciation of the services rendered therewith by Fred W. Herbert, director service department, N. E. L. A.

TABLE I

DATA ON CUSTOMER OWNERSHIP

SUMMARY OF INFORMATION REPORTED BY 251 ELECTRIC LIGHT AND POWER COMPANIES

Total population of territory served	85,564,726
Total number of customers served	17,935,530
Gross electric earnings of combined companies reporting (1928)	$1,171,105,657
*Number of individual stock sales through Customer Ownership Plan	1,884,148
Shares of stock sold through Customer Ownership Plan ($100 par.)	18,800,307
Percentage of electric customers buying stock under Customer Ownership Plan	10.5%
Percentage of shares sold on deferred payment plan (1928)	16.2%
Weighted average selling cost per share	$3.12

SUMMARY BY YEARS

Year	*Sales Made	Shares of Stock Sold	Number of Additional Companies by Years Adopting Customer Ownership Plan
1914	4,044	92,310	7
1915	4,357	57,130	3
1916	3,681	38,183	4
1917	8,242	82,007	8
1918	5,186	42,388	7
1919	19,872	194,021	12
1920	53,063	454,139	34
1921	118,544	830,222	37
1922	156,725	1,450,707	49
1923	279,186	1,806,300	24
1924	294,467	2,478,165	23
1925	236,043	2,926,271	18
1926	248,867	2,686,187	2
1927	249,491	3,581,206	18
1928	202,380	2,081,071	5
	1,884,148	18,800,307	251

*In the compilation of these statistics, each separate purchase of stocks has been recorded by many of the reporting companies as being the acquisition of an additional "stockholder." There are possibilities of duplications, arising from:

(a) Repeat purchases of stock of the same company by the same individual.

(b) The purchase of stock in two or more companies by the same individual.

(c) In addition, the situation is further complicated by the purchase of stocks, by customers, from other sources than through the company's office.

TABLE I—(*Concluded*)

DATA ON CUSTOMER OWNERSHIP

SUMMARY OF SALES IN 1928

Common Stock Shares	56,862
Preferred Stock Shares	2,024,209
Total	2,081,071
Value of stock sold under Customer Ownership Plan, 1928 ($100 par)	
Common Stock	$5,686,200
Preferred Stock	202,420,900
Total	$208,107,100

Analysis of the returns of companies reporting in full on the detailed information asked for on Customer Ownership questionnaires developed the following data.

Of the total individual sales made under Customer Ownership Plan—

87.2% were to Customers
8.7% were to Employees
4.1% to others.

100%

Of the total number of shares of stock sold under Customer Ownership Plan—

85.4% was sold to Customers
9.0% was sold to Employees
5.6% was sold to others.

100%

Average percentage employee stockholders to total employees	15.4%
Average number of shares per employee	10.7
Average number of shares per customer	10.3

THE TEN CARDINAL RULES OF CUSTOMER OWNERSHIP

Prepared by the Customer Ownership Committee of the National Electric Light Association

1. The sale of the securities must be direct from company to customer or through an agency expressly created for the purpose and controlled by the company.

2. The safety of the securities offered must be amply protected by property and earnings.

3. A minimum rate of dividends must be provided for insofar as honest judgment based on experience can foresee.

4. A reliable resale market must be maintained in some manner so that shareholders who wish to dispose of their holdings can do so promptly at nominal expense.

5. A partial payment purchase plan must be operative in order to give every customer who can save a small amount monthly full opportunity to become a shareholder, and to encourage thrift.

6. The proprietary interest and responsibility of shareholders must be emphasized and the shareholders supplied regularly with information regarding their company and its affairs.

7. Loss of capital by shareholders in hazardous and fraudulent offerings from various sources must be guarded against by the rendering of authentic information and advice to shareholders.

8. The number of shareholders must be increased steadily and efforts should be made to avoid large individual accumulations of stock.

9. Employees must be carefully instructed in order that all representations made to customers or others are in line with the facts.

10. Managements must realize that customer ownership multiplies their obligations to the public and intensifies the trust reposed in them. It does not replace the constant striving for higher efficiency, good service, reasonable rates, courtesy and progressive public relations policies.

TABLE II

SUMMARY BY STATES

State	Population Served	Customers Served	Number of Stock Sales	Shares Sold
Alabama	2,165,020	186,171	39,363	318,077

APPENDIX A

U. S.

Murphy v. The Wyandotte County Gas Company (Dist. Ct., Dist. Kan., 1st Div., November 2, 1928).

In suit by holder of one share of stock of corporation to restrain it from using its employees in selling securities of another corporation which owned majority of stock of former, and no other stockholder joined suit, nor did it appear that value of plaintiff's stock was impaired, bill dismissed under Equity Rule 27—"Customer ownership" and "employee ownership" of securities of public utilities discussed.

The opinion of Pollock, Dist. J., follows in full:

This suit is brought by plaintiff as minority stockholder in defendant corporation, and as alleged in the bill of complaint, for the benefit of all other minority shareholders in said corporation, to restrain the corporation from employing its official force, agents, servants, and employees in the performance of duties and services for the sale, use and benefit of a corporation created under the laws of the state of Delaware called the Cities Service Company, the owner of the majority of the capital stock of defendant company. The business which the bill seeks to restrain the defendant company from doing for the holder of the majority of its capital stock, consists in putting on selling campaigns to sell to customers of defendant company and others, shares of stock and securities of the Cities Service Company, said Cities Service Company being a mere holding company, owning and holding a majority of the shares of stock in defendant company and thus controlling, through a majority vote of its shares, the choice of officers and directors in defendant corporation.

The purpose for which defendant company was incorporated under the laws of this state as expressed in its charter and as admitted in the pleadings is as follows:

> "Of supplying gas to the public, and that defendant is possessed of the powers necessary and incident to the carrying out of such purpose."

Now the question presented is this: Is the engaging in a campaign of selling the stock, bonds and other securities of the Cities Service Company, the owner and holder of the majority of the capital stock of defendant company, through the direction and under the authority of the officers and directors of defendant corporation, by those in the employ of defendant and paid their salaries and wages out of the treasury of defendant company alone during working hours, for which time defendant company pays and is entitled to the services of such employees, so foreign to the lawful purpose for which defendant was incorporated as to be *ultra vires* and an abuse of the trust created between defendant company and its stockholders created by those purchasing the majority of its stock, and by such majority holding, electing its governing bodies?

While two questions are presented, the answer to both will be found in the answer to one other question: Does "customer ownership" and "employee ownership" of stock bear a rational relationship to the success of a corporation? If it does, the decision of the Board of Directors, if made in good faith, cannot be reviewed by the courts. The Courts have enough to do without sitting as a board of review over the acts of boards of directors.

There is little room for dispute as to the law applicable; much more room for fair argument as to the facts. If the officers of defendant company are using the machinery of the corporation, their own time and that of the employees, their lists of customers, and the name of the corporation, to sell stock of another company, it can be, and should be enjoined at the instance of any stockholder. In the first place the company was granted a charter for the purpose of selling gas, and not selling stock. It can't go into the stock selling business, even if a commission on the sales went directly into the corporate treasury, and even if it was a profitable business, for the simple reason that it has no corporate authority to do so. A minority stockholder can stop it, for the reason that when he acquired his stock he had a right to rely on the corporation staying in the business he wanted to invest his money in, and not going into another business he didn't want to go into. It makes no difference whether the other business is more profitable; the stockholder may insist on the officers sticking to the particular business he set into, until the charter is changed by the necessary vote of the stockholders. *Hawes* v. *Oakland,* 104 U. S. 450; 6 *Fletcher on Corps.* 6900; *Dodge* v. *Woolsey,* 18 How. 331, 15 L ed. 401; *Smith* v. *Title and Trust Co.,* 225 U. S. 180; *C. J.* 14A. p. 155.

The Kansas statute authorizing a corporation to own stock of another company in a similar line of business (17-603) has nothing to do with this case. The defendant company does not buy, sell, or own any of the securities of the Cities Service Company.

Aside from the question of *ultra vires,* there is another reason; a board of directors is under a fiduciary obligation to every stockholder. If an officer of a corporation, a board of directors, or a majority of the stockholders, use their power for their own profit, rather than for the good of the corporation, it may be enjoined. Where the majority of the stock is owned by another corporation, dealings between the two must be rigidly scrutinized.

> "Under the circumstances disclosed in the evidence, the fact that the American Tel. & Tel. Co. controlled the Company and the Western Electric Company is not important beyond requiring close scrutiny of their dealings to prevent imposition upon the community served by the Company, but the Court recognized and applied this rule."

Houston v. *S. W. Bell Tel. Co.,* 259 U. S. l. c., 323.

> "The defendants have criticised this payment because the close relationship between the American Tel. & Tel. Co. and the plaintiff may overburden the plaintiff with an undue expense account for the benefit of the American Tel. & Tel. Co. This subject and this danger have been considered in many other cases, and it has been held that such a relationship between the two companies may require a close scrutiny of the intercorporate dealings."

N. W. Bell Tel. Co. v. *Spillman,* 6 Fed. (2d) 664 l. c.

> "One who owns the majority of the stock of a corporation and who dominates and controls such corporation may contract with the corporation, and such contract will be upheld where the consideration moving to the corporation is adequate, where the terms of the contract are fair to the corporation, and where the contract will further the best interests of the corporation. But a court of equity will hold such majority stockholder to the observance of the highest rectitude in dealing with the corporation, and where the contract is unfair or unconscionable, where the consideration is inadequate, or where the contract is not for the best interests of the corporation, but subserves the selfish interests of such stockholder, it will set aside such contract at the instance of the corporation or its minority stockholders."

Heim v. *Jobes,* 14 Fed. (2d) 32 l. c., 8th C. C. A.
Wheeler v. *Bank,* 159 Fed. 391. 8th C. C. A.,

speaking through Mr. Justice Sanborn:

> "The holder of the majority of the stock of the corporation has the power, by the election of biddable directors and by the vote of his stock, to do everything that the corporation can do. His power to control and direct the action of the corporation places him in its shoes, and constitutes him the actual, if not the technical, trustee for the holders of the minority of the stock."
>
> "This devolution of unlimited power imposes on the single holder of the majority of the stock a correlative duty, the duty of a fiduciary or agent, to the holders of the minority of the stock, who can act only through him, the duty to exercise good faith, care, and diligence to make the property of the corporation produce the largest possible amount, to protect the interests of the holders of the minority of the stock, and to secure and pay over to them their just proportion of the income and of the proceeds of the corporate property."

It is, of course, also true that after giving to such transactions the close scrutiny required by the law, if there is no fraud and no subterfuge, and the propriety of the transaction is none of business judgment, the courts will not interfere.

> "There is nothing to indicate bad faith. So far as appears, plaintiff in error's board of directors has exercised a proper discretion about this matter requiring business judgment. It must never be forgotten that while the State may regulate with a view to enforcing reasonable rates and charges, it is not the owner of the property of the public utility company and is not clothed with the general power of management incident to ownership. The applicable general rule is well expressed in *Public Utilities Commission* v. *Springfield Gas & Electric Co.* 291 Ill. 209, 234.
>
> " 'The commission is not the financial manager of the corporation, and it is not empowered to substitute its judgment for that of the directors of the corporation; nor can it ignore items charged by the utility as operating expenses unless there is an abuse of discretion in that regard by the corporate officers.'
>
> "See *I. C. C.* v. *Rwy. Co.,* 209 U. S. 108; *Rwy. Co.* v. *Wisconsin,* 238 U. S. 491; *People* v. *Stevens,* 197 N. Y. 1; *Tel. Co.* v. *Commission,* 262 U. S. 276, 288."

> "Within the limits of their authority directors or trustees possess full discretionary powers, and in the honest and reasonable exercise of such powers they are not subject to control by the stockholders or by the courts at the instance of a stockholder. A distinction has been admitted between the jurisdictions of courts of equity to accord relief at the suit of stockholders where the action is to redress breaches of trust on the part of directors or to recover damages from the same, and the want of jurisdiction in such courts, where the object of the bill is to influence corporate action, or where in its result it will have this effect. The true distinction is between acts in excess of the powers of the directors and in breach of their trust, and acts which are within their powers and which merely involve an exercise of the discretion committed to them. The rule is that in the absence of usurpation, of fraud, or of gross negligence, courts of equity will not interfere at the suit of a dissatisfied minority of stockholders, merely to overrule and control the discretion of the directors on questions of corporate management, policy, or business. Certainly in the absence of any action by the stockholders to control the directors, the courts will not interfere at the instance of the minority stockholders with the acts of the directors, which are within the scope of their powers and are not fraudulent or in breach of trust." *C. J.* 14A. 83.

This brings us to the controlling question in the case: are these stock selling campaigns put on in order to dispose of the stock of the Cities Service Company, for its benefit—to find a market for stock otherwise not available? If so, the relief prayed for should be granted. On the other hand, if it is an effort made, in good faith, to further the corporate business of the defendant, the court cannot interfere. The question of whether or not the stock sold is a good investment is quite beside the question. Courts cannot act as guardians of the investing public; that function, if it is properly a governmental function at all, is for the legislature and blue-sky boards of their creation.

It must be conceded that the business of selling gas to the public is a broader one than the construction of mains, connecting houses, and rendering bills. A public utility must find and satisfy its customers; it lives in an atmosphere of legislation; unfriendly legislators, whether in the City Hall or in the State House, by restrictive or unfair enactments directly affect the balance sheet of the corporation and the dividends of the stockholders. An unfriendly public too often makes itself felt in the actions of legislators who are hypersensitive to public opinion. Gas competes with coal and electricity for its market, and whatever tends fairly to increase the market is legitimate. Small corporations and large ones, in private business and public utilities, have from time immemorial "placed" part of their stock with good customers, either actual or potential. The bill in this case alleges that, "the present and future success of said defendant company depends in substantial part on its relations with the general public in this community."

This is, of course, true. In the past few years the matter of customer ownership has received the attention of the boards of directors of a great many corporations. The fact that many of the greatest of them have adopted it as a business policy is proof enough that it is a matter of business judgment. The railroads, the telephone companies, the electric power companies, the street car companies, provide easy means of inducing their customers to become owners. Invitations to become interested in the company are found inside telephone booths; placards invite passengers on street cars to, "Ask the motorman about our stock"; the periodicals carry advertisements of the wide dissemination of stock among patrons of the advertisers.

If a board of directors believes it will advance the interests of the company to interest its patrons in its problems; to give financial interest to its customers who will recommend to their neighbor its service over that of its competitor; to displace an unfriendly and suspicious public with one which is financially interested in its welfare; if done in good faith, there is nothing illegal about it. The decision of *Thrailkill* v. *Railroad Company,* 246 Fed. 687 (8th C. C. A.) controls in principle. The defendant in that case paid a commission to real estate agents for selling land in which the railroad had no interest. Such sales, however, brought settlers to the land, and settlers meant freight business. The contract was held valid and within the corporate power.

The fact that the stock sold is not that of the defendant, but that of its parent company, is not controlling. That situation exists in many instances. If the defendant company prospers, its prosperity is reflected in the value of the stock of the parent company sold to the public. Such prosperity is a degree removed, the value of the stock sold depending on the prosperity of other subsidiaries, but the legal situation is not changed by the extent or directness of the interest. The customer still can help himself by helping the defendant company in its problems. I conclude, therefore, that if these stock-selling activities are conducted in good faith, and for the *sole* purpose of giving its customers a financial interest in the business, and thus improving its balance sheet, there is no reason for judicial interference.

As to "employee ownership" the question is even more free from doubt. An employee who has a financial interest in the company he works for is apt to be a better employee; he gives better measure for his wage; he is more contented with his job; less apt to be disgruntled when called upon to do extra work; and much less apt to strike. All over the country employers are seeking to interest their employees in the business, for it is a proper rule of human nature that a man's heart is close to his pocket-book. In small business, he is given a bonus depending on the success of the year's work; in larger ones, like the steel companies, the railroads, the great utilities, he is given preferential rights to acquire an interest, on favorable terms, and on long-time payments. The past has proved the economic soundness of the proposition that an employee should have a financial interest in the success of his company.

A great many cases have been decided which have a bearing upon this proposition. In recent years corporations have found it to be sound business to build up a morale among their employees, for the purpose of making their positions attractive so that they can command the services of a better class of employees. The boards of directors have used corporate funds to construct hospitals for the use of their employees; playgrounds for their recreation; have contributed to pension funds and for disability benefits; have granted bonuses, not a part of the contract of employment, for special meritorious service, or because the combination of capital with the work of the employees have resulted in a prosperous year for the company. These cases are gathered in two extensive notes, one appended to the case of *Dodge Brothers* v. *Ford Motor Company,* 3 A. L. R. at page 443; and the other appended to the case of *Putnam v. Juvenile Shoe Corporation,* 40 A. L. R., page 1423. A rather clear distinction was drawn in the *Ford Motor Company* case by the Supreme Court of Michigan, which is this: As far as the Board of Directors in that case believed it to be good business to pay their employees a somewhat higher rate of wage than other industries were paying, it was held to be a valid exercise of corporate power; as far as their actions, however, were dictated by a motive to benefit humanity in general, was held to be beyond the power of the Board of Directors. The Supreme Court of Michigan said:

> "The difference between an incidental humanitarian expenditure of corporate funds for the benefit of the employees, like the building of a hospital for their use and the employment of agencies for the betterment of their condition, and a general purpose and plan to benefit mankind at the expense of others is obvious. There should be no confusion (of which there is evidence) of the duties which Mr. Ford conceives that he and the stockholders owe to the general public, and the duties which in law he and his co-directors owe to the protesting minority stockholders. A business corporation is organized and carried on primarily for the profit of the stockholders. The powers of the directors are to be employed for that end. The discretion of directors is to be exercised in the choice of means to attain that end, and does not extend to a change in the end itself, to the reduction of profits, or to the non-distribution of profits among stockholders in order to devote them to other purposes.
>
> "There is committed to the discretion of the directors, a discretion to be exercised in good faith, the infinite details of business, including the wages which shall be paid to employees, the number of hours they shall work, the conditions under which labor shall be carried on, and the price for which products shall be offered to the public."

That leaves but one question and that a question of fact applicable to this case alone. Conceding the right of a board of directors to do these things if done in the sole interest of the corporation, the question still remains of whether, in this case, the directors are so actuated, or whether they are in fact simply using the facilities of the defendant to sell stock for the parent company. If they are so actuated, or if the result of their activity is to benefit only the parent company, then their acts violate their duty to the plaintiff. The amount of the facilities used, the amount of time and energy spent for the improper purpose, is not material, except as it may affect the jurisdiction of a United States District Court. The quality of the act of an officer of a bank who would steal a dollar bill is the same as if he had stolen the bank itself.

Under the circumstances as shown by the evidence in this case, a very difficult question of fact is presented. On the one hand is a presumption that the directors of a corporation are acting in good faith and for the sole interest of the stockholders whom they represent, together with the natural reluctance of courts to interfere in the management of private business; on the other is the even stronger demand that the acts of trustees be rigidly scrutinized, and the jealous regard which courts accord a situation where a trustee is dealing with himself. The Cities Service Company owns a majority of the stock of the defendant company, and through a board elected by that stock, uses the facilities of the company to dispose of securities issued by or owned by itself. Under such circumstances it must clearly appear that its actions are primarily for the benefit of the defendant. It is unnecessary to decide the question, in my judgment, for this reason.

This is an equity case, brought in this court by the holder of one share of stock of the par value of $100.00. The jurisdiction depends on diversity of citizenship. The suit is brought under Equity Rule 27, which reads in part as follows:

> "Every bill brought by one or more stockholders in a corporation against the corporation and other parties, founded on rights which may properly be asserted by the corporation, must be verified by oath, and must contain an allegation that the plaintiff was a shareholder at the time of the transaction of which he complains, or that his share had devolved on him since by operation of law, and that the suit is not a collusive one to confer on a court of the United States jurisdiction of a case of which it would not otherwise have cognizance. It must also set forth with particularity the efforts of the plaintiff to secure such action as he desires on the part of the managing directors or trustees, and, if necessary, of the shareholders, and the causes of his failure to obtain such action or the reasons for not making such effort."

The rule is well settled that a stockholder may enjoin the doing of an *ultra vires* or illegal act; or enjoin a threatened act of a board of directors who are acting in their own interest and not that of the corporation; or where the board fraudulently refuses to prosecute a claim belonging to the corporation. All such suits are brought for the benefit of the corporation.

14 *C. J.* 924;
Thompson on Corporations, Sec. 4563 *et seq.*

For the purpose of jurisdiction of the United States Courts it is settled that the amount in controversy is the value of the right of the corporation, and not the right of the plaintiff stockholder. The thing in controversy is the right of the corporation. *Larabee* v. *Dolley,* 175 Fed. 365 (reversed on other grounds); *Hutchinson Box Board Co.* v. *Van Horn,* 299 Fed. 424 (8 C. C. A.) and cases therein cited.

It appears in this case that the plaintiff owns but a single share of stock of the par value of $100.00; notwithstanding the invitation to other stockholders to join in the suit, no other has done so; it does not appear that the things complained of have impaired the value of the plaintiff's stock.

> "If the injury is slight and affects all stockholders alike and no other stockholder complains, it will not ordinarily afford ground of equitable relief."

Thompson on Corporations, Sec. 4567.

In *General Investment Co.* v. *Lake Shore Ry Co.* 269 Fed. 235 (6th C. C. A.) the court said:

> "Further, we notice that plaintiff owns only one-thousandth of 1 per cent of the capital stock, that no other shareholder has accepted its invitation to join in preventing the imminent irreparable injury, and that this interest plaintiff bought after the consolidation contract was made. He seems to be a volunteer rather than a conscript. We have, then, a case where a private suitor, with a minimum of ponderable interest, and with no disposition to beware of entrance to a quarrel, is seeking relief upon the sole ground that the public policy of the State is being violated, and where the State authorities have long acquiesced and do acquiesce in any violation there may be. Under such circumstances the court of equity will be strict in requiring the plaintiff to point out with precision and certainty in what respects the law is about to be violated, and to show, clearly and positively, substantial and irreparable injury to its private rights. A measure of imperfection in pleading that might well be overlooked in the ordinary controversy should not be disregarded in such a case as this."

It is the purpose of Equity Rule 27 to protect the United States Courts from imposition. Under the circumstances I do not feel that the plaintiff has brought himself within the rule and authorities cited, and the bill will be dismissed.

TRAINING FOR BETTER PUBLIC CONTACT—II ANALYSIS OF PUBLIC-CONTACT WORK

INTRODUCTION

The results of the survey outlined in the preceding report on public-contact training† indicate that considerable work is being done in this field, but as yet little has been done to definitely establish uniform methods in the attack on the problem. The purpose of this report is to outline a method of analysis of public-contact work which will bring to light the nature and range of contacts, and to arrange this information in suitable form to be used as a basis for the preparation of a training program.

Due to the nature of the electric light and power business, there are a multiplicity and variety of contacts with the public. There are very few departments in an electric utility which do not have at least some contact with the public. In setting up any comprehensive public-contact training program, it is necessary, first, to consider the nature of these contacts and of the problems created by them, and, second, to decide which of these problems that may be grouped for study are to be found in the work of each employe, each division, or department of the organization.

This report deals only with the analysis of the work, and in the next report consideration will be given to suitable training methods. The arrangement of material is suggestive of the items which must be taken into consideration, and in applying this method of analysis to any particular company, each subdivision must be expanded so that it will cover all the details.

PERSONAL REQUIREMENTS

Traits Necessary for Particular Items of Work

Special emphasis has been placed upon the necessity for considering the traits of the individual before he is assigned to a particular line of work. It is especially important that these factors be considered in any job in which a large portion of the time is spent in contact with the customers. While this report is concerned primarily with an analysis of the work with reference to training requirements, it must be assumed that reasonable care has been taken in the first place to select from the applicants for any given type of work the persons who are best fitted for it.

The holders of all contact jobs must, first of all, be courteous and reasonable. They must be willing to listen to, consider the statements made by, and to appreciate the needs and wishes of, the customers with whom they deal. While all public-contact employes should possess these traits, each particular job or group of jobs requires the possession of certain other characteristics. Since every employe does not have these to the fullest extent, an effective training program must be so designed as to bring to light and correct any weaknesses.

Physical Characteristics and Appearance Necessary for the Work

A customer quickly reacts favorably or unfavorably to an employe, depending upon his or her apparent fitness to perform the work at hand. To be specific, in the selection of delinquent-bill collectors, a wise department head would select neither undersized men nor men so oversized as to appear to be bullies. In selecting or retaining men who repair customers' appliances, a wise company would not keep men on that particular job who were so obviously crippled as to interfere with their work. In choosing men or women to answer customers' telephone calls, somewhat deaf employes would obviously be misplaced. Just as physical characteristics play a part, so do dress and care of the person. The chief factor which any training program would include on this point would be emphasis on the appropriateness of the clothing worn by the employe concerned.

NATURE OF RESPONSIBILITY

Non-Supervisory

In setting up a training program, consideration must be given to the fact that the nature of the responsibility of members of the non-supervisory force differs from that in the supervisory force. The fact that employes in non-supervisory jobs have largely to do as instructed by superiors has frequently resulted in a lack of study of the requirements of their work. Supervisors have been given blanket responsibility and frequently allowed to devise whatever methods they choose for training and for checking the results of the work of subordinates.

While contact employes are not always under the eye of the supervisor, nevertheless they are acting under his instruction. Each of them is delegated certain responsibilities which are small or large in proportion to the amount and importance of the work, which he does without immediate supervision. Especially in customer-contact positions, the jobs of non-supervisory employes must be carefully analyzed to make certain that there is proper selection and training.

Supervisory

Supervisory jobs carry much greater responsibility. The supervisor is charged with the proper training of his subordinates, and with seeing that his instructions are carried out. The customers generally look to him, more as a representative of the company and management, and expect a broader consideration of the question or problem under discussion. Both the customers and the subordinates look to the supervisor as the spokesman for his par-

† Training for Better Public Contact—Its Necessity and Importance (Publication No. 278-52).

ticular division. He is considered by his subordinates as setting the standard of manner and attitude in his dealings with customers.

Because of the facts just mentioned, supervisors must be selected for many other reasons than simply that they are good workmen, and their jobs must be analyzed to make certain that they are familiar with the outstanding responsibilities and know how to carry them out properly.

LOCATION OF CONTACT OCCURRENCES

On Customers' Premises

A large number of daily contacts take place in the homes or business places of customers. Employes must understand that, when working in such locations, they are virtually guests. They are in the position of outsiders who, while rendering a service, are nevertheless doing so on someone else's property, and, for this reason, while there, they should especially respect the wishes of the customers as to their actions.

On Company Premises

Another class of contacts occurs when the customer comes to the company's place of business. Here the employe is the host. The customer has come to him for advice or help, or to make a purchase. The employe must remember that he is the host, and that this position requires the same courtesy to a customer as to any other guest.

NATURE OF CONTACT

Contacts with customers fall into three classes: Personal, telephone, and by letter. In studying the nature of each of these types of work, certain factors must be stressed. An employe, for example, should be expected to be courteous in any of the three situations; he should be just as considerate of the customer's viewpoint; and in every case he should be equally careful to correctly and completely explain the company's position.

Personal

Personal contacts are generally the most numerous. In these contacts the employe meets the customer face to face. Here, naturally, personal appearance must receive attention. In addition to that, the employe must be able to readily understand the customer in order to transact business with him.

Telephone

In telephone contacts, proper use of the voice is an important asset because it must be both pleasant and easily understood, as there is no opportunity to please a customer by smiles or other devices which may be used in a personal contact. In order to avoid unnecessary transfers, knowledge of the company is necessary. Any customer naturally becomes extremely irritated if transferred several times in attempting to reach the proper individual or department. Proper methods of answering the telephone are essential to good public relations. Since this type of contact is so important, it deserves special training methods and, therefore, requires special attention in the analysis of public contacts.

Correspondence

In correspondence contacts, aside from the mechanical rules, clearness, completeness, and sufficient friendliness must be stressed so as to get away from the cold formality of the old-time business letter. It should be remembered that, since the letter is the medium of contact, the company's representative should be able to so carefully phrase his statements as to secure the same pleasant reaction from the customer as should be accomplished in a personal interview.

CLASSIFICATION OF CONTACTS

The division of contact work which follows is a theoretical set-up and might not fit, as it stands, the needs of any one company. However, it can be used as a guide in making a set-up in any company. The basis of classification has been chiefly the amount or type of personal contact involved in any particular type of work. It has been found that the contact work in an organization can be divided into certain groups on the basis of the similarity of their public-relations problems. In many companies a contact employe may perform more than one of these lines of work. For this reason contacts have been analyzed from the standpoint of the work rather than of the jobs as found in any particular company.

In analyzing any particular job, having assigned it to a group on the basis of its general characteristics, it is necessary to break it up further. Is it supervisory or non-supervisory? Is it performed on the customer's or the company's premises? Is it carried on face to face, over the telephone, or by correspondence? Is it, from its very origin, likely to be a pleasant or an unpleasant contact?

It is evident that certain traits are necessary for the holder of each position. It is only by breaking up the positions through a study of their various parts, duties and responsibilities that a determination of the traits necessary can be made.

Functions With Incidental Personal Contact

Bill Delivery
Meter Reading

Certain work, while involving a large number of customers daily, only incidentally necessitates personal contact, which in itself ordinarily does not involve many company policies or serious problems. In the work of delivering bills and reading meters, it appears that practically the only contact consists in inquiring for the location of a particular mailbox or meter. However, there are a great many factors which must be taken into consideration in analyzing this work, to determine the necessary traits or qualifications.

How can the bill-delivery boy's position be analyzed in order to know what should be emphasized in a training program? His personal appearance is of importance, because he reaches every customer's home or place of business once a month, and, aside from the meter-readers, he may be the only representative of the company that many customers see at regular intervals. He should be neatly dressed and have an alert appearance. He should be able to so route his bills that he will not have to retrace his steps any more than necessary. He should be able to quickly answer or refer the customer to the individual who can answer such common questions as, "Why didn't I receive my bill last month?" "Why is my bill so large?" Why is my bill late?" and "Where can I pay my bill?"

His job is non-supervisory, and, because he is usually a youngster, his instructions must include many cautions on what to do or what not to do in various circumstances. Since his work is largely on customers' premises, he is to respect the normal wishes of customers by not "cutting across" lawns, slamming doors, and otherwise behaving in an ungentlemanly way. Since he is usually recognizable as the bill deliverer of the company, he must realize that his whole manner is being observed by all who happen to see him, and that they are measuring the company frequently according to the way in which he conducts himself.

His contacts are entirely personal. For this reason, in addition to suitable appearance, his manner of speech must be satisfactory. He must be readily understood, and the information which he gives must be in sufficient detail so that it will be unnecessary for the customer to call the company on the same question.

This brief analysis of the bill-deliverer's job gives an idea of the sort of thing that must be done before any method of training can be set up for any job. It can be seen that about the same problems confront the meter-reader as the bill-deliverer. However, before attempting a training program with meter-readers, it would be necessary to make a similar analysis to determine what additional points should be stressed.

In grouping the various types of work in the divisions which follow, the same idea has been kept in mind, that is, that the chief problems and the chief traits necessary to the holders of public-contact jobs are generally similar within any group.

Functions With Major Personal Contact

Information giving
Cash receiving
Stock transferring
Delivering merchandise
Delivering lamps
Policing
Renewing lamps
Application taking
Telephone service order taking
Using the telephone

This list includes the public contacts in which there is a larger personal element. In all of them, however, the contacts are more likely to be pleasant than disagreeable. They are largely routine transactions which involve personal conversations with customers. It should be noted that the last three types of work in the list may be specially classified because they are carried on chiefly over the telephone. For them, of course, the result of the analysis would be quite different from that for the others.

These positions are all predominantly routine, and the outstanding characteristic necessary in any holder of the routine position involving public contact is that the personal side of the business shall not be completely overshadowed by the routine side, or, stating it differently, the holder of any of these positions must be as proficient, and conscientious in his methods of pleasing the customer, as he is in handling the routine of the job. The very fact that the work is routine and highly repetitive is likely to result in the employe becoming mechanical in his attitude as well as in his work. He must not forget that, while any particular transaction is only one of many similar ones to him, to the customer it presents a real personal problem which he expects to be solved to his satisfaction. It can be seen that some of the work is supervisory and some non-supervisory; some is on customers' premises and some on the company premises; some is face to face and some is via the telephone. They are all more or less routine transactions with a major element of personal contact.

Functions With Ultra-Difficult Personal Contact

Delinquent-bill collecting
(including attorney's office)
Bill or complaint adjusting
Establishing credits

Here are the situations which are disagreeable from the start. All of them involve money either for payments past due or for payments about which there is some question. The problems, therefore, are of a peculiar nature. Obviously in this group certain characteristics are generally necessary. These include open-mindedness in getting the customer's explanation, sense of company responsibility, and positiveness. Since practically all of this work is done by individuals acting alone, they must be especially responsible. They must appreciate not only the necessity for getting money for the company, but also the fact that there are many peculiar conditions affecting the customers' financial situation which must be weighed in making any decision.

Technical Service With Personal Element

Inspecting meters
Inspecting wiring, and new or altered installation
Inspecting conduits
Testing equipment
Obtaining right-of-way

With the exception of the last, which requires some special explanation, all these contacts are more or less routine and should be agreeable. They are largely for the purpose of seeing that equipment is kept at the standard required in order to render the best possible service to customers. The holders of any of these positions should, first of all, be good technicians. No amount of courtesy will overcome faulty performance. They are engaged in a type of work which is largely for the benefit of the customer in that it helps in assuring him that there will be the fewest possible interruptions in his service. Holders of these jobs, however, must not be simply technicians who coldly disregard human curiosity, for example, about subjects with which most laymen are not familiar. Since their work, especially in connection with new construction, may delay or hasten the connection of the service to the company's lines, it is to both the customer's and the company's advantage that men in this service do their work quickly and so well that there is no necessity for immediate repetition.

All these items of work are transacted on the customers' premises, where the employes are likely to be questioned about the process and about many other things of a technical nature. Employes holding such positions should be able not only to do good work, but to show the customer how the work fits in with the general company plan of service to the customer.

Obtaining right-of-way is included in the list above because it is "technical service with a personal element." It obviously demands a much more diplomatic type of person, because very frequently objections have to be removed. It is concerned, too, with seeing that the lines are placed in such a position and route that the customers may get the best possible service, but it involves the additional feature of using one person's property for the benefit of another, the securing of permission to use which requires particular ability.

Mechanical Service With Personal Element

1. Constructing Outside Equipment

Men engaged in this work have rather infrequent conversations with customers, but are seen by, and their talk among themselves is overheard by, many customers. For this reason they must be cautious as to what not to do or say, because of the possible reaction on the customers. Frequently the nature of the work attracts onlookers who ask questions. Proper answering of these questions by the foreman often satisfies a bit of curiosity, which produces a very good effect on the questioner, who is probably also a customer.

2. Installing Inside Equipment

Electrical Mechanics
Meter Setters

Men engaged in this work have frequent contact with the customer in the case of additions to existing service facilities. In the case of new customers, who are anxious to obtain service, these men can help materially in building good customer relations. These employes are among the first to deal with the customer, as they are constantly under the observation of the customer they must be extremely careful in their conversation, actions, and appearance.

3. Maintenance and Repair Service

Answering Trouble Calls
Patrolling Lines
Repairing Appliances
Re-fusing and Repairing Services

Men engaged in these activities are almost always dispatched to a particular location because something has gone wrong with the customer's or company's equipment. In such a case, the customer is naturally irritated because of the interruption. This being true, the employe has the opportunity not only to repair the service and thereby remove the cause of the customer's ill-feeling, but also, by his attitude and actions, to appease the feeling caused by the trouble. Here again, men engaged in these lines of work must be good mechanics. Simply saying, "I am sorry" and not making a satisfactory repair will not satisfy a customer. Similarly, making a repair in a manner which seems to indicate that the repairman would rather be doing something else falls far short of accomplishing its purpose.

Even the appearance of the repairman has its influence on customers' feelings. The clothing worn does not have to be disreputable nor the mechanic's appearance generally untidy simply because he works with tools. His clothing should be appropriate to the work at hand. Since he is answering trouble calls, he should know the kinds of tools and equipment necessary to make the repairs so that he can work rapidly after getting on the job. He must expect and be willing to answer carefully and satisfyingly customers' questions as to the reason for the difficulty. If the interruption to the service was due to some act on the customer's part, the repairman or troubleman should courteously indicate how such an act could be avoided in the future, and thus save the customer time, trouble, and expense.

Sales Contacts

Lighting
Power
Signs and sign lighting
Domestic appliances (stores; house-to-house)
Industrial appliances

Here the utility is definitely seeking to add to its revenue by securing new business. Employes holding positions of this sort should be especially grounded in business ethics, in addition to the usual factors of courtesy which are expected of any employe. They should realize their responsibility in trying not only to sell additional load, but the company as well. Since their work is salesmanship, they should have that skill highly developed. This involves the ability to express themselves clearly and to the point. It involves a knowledge of the services obtainable from competitors.

In selecting salesmen consideration should be given to their honesty, dependability, and forcefulness. They should avoid the use of high-pressure methods and should develop the use of proper load-building methods, which will result in an ultimate satisfaction to the customer and the company alike.

Incidental Social Contacts

Every employe in a company has social contacts of one sort or another. Because he is employed by a utility, he is frequently asked questions about various things connected with his organization. He should be able to answer these questions in such a way as to satisfy the questioner; naturally, he should give adequate answers about his own department and be able to direct the questioner to the proper source of information about any other department.

As a representative of a public utility, he must remember that he is a public servant, and that more is expected of him than of an employe of a purely private industry.

Publicity Activities

The employes who compose the advertising material for the company must be sufficiently familiar with company policies and methods to honestly tell the story of an honest company.

Public Speaking

Any utility employe who addresses audiences under the auspices of his company should be well grounded in the principles of correct speaking and in the fundamental policies of the company which he represents. Only those employes who have indicated to the satisfaction of a responsible member of their organization their ability to represent it properly should be given the privilege of doing so, especially as on many occasions questions are asked of the speaker after his address.

Membership in Civic and Community Organizations

When an employe enters any organization more or less as a representative of his company, he should be sufficiently familiar with company policies and problems to know how to represent his organization in the manner in which it wishes itself represented.

METHODS OF ANALYZING PERSONAL SERVICE ELEMENTS OF PUBLIC-CONTACT JOBS

Having recognized that public contacts may be classified in various ways, decision must be made as to the method to be used in analyzing the work, so as to locate the difficulties which the training program should help to overcome or eliminate. The training method in use for other phases of the work probably will have the greatest bearing on the selection of the method to be used for public-contact training.

Any one of three situations may exist. First, the company may maintain a training department that makes the analysis of the work, prepares the training material, and conducts the training program. In this method, the line organization must cooperate by giving the training department such assistance as it requires in the collection of information about the work. The advantage claimed for this method is that all of the training work is carried on by the experienced training staff, and in addition, the program is carried out with more dispatch and effectiveness.

In the second situation, the training department may exercise functional supervision over these matters, while the line organization departments are held responsible for the training activities. In such a case the training department will furnish staff assistance and consultation to the line organization in the work analysis, in preparing the training material, and in the conduct of the training program. The advantage claimed for this method is that it places the responsibility for training on the line supervisors and insures better cooperation on their part in the training program. It is also claimed that this method tends to emphasize the fact that personal service is as much a part of the contact job as are the mechanical phases of the work. It is also contended that this method is more likely to insure continuity of training effort and follow-up on the part of the supervisors, than is the case where they are relieved of the responsibility for training. However, some students of training feel that it is a waste of time and effort to attempt to get the line organization supervisors to carry on the training program.

The third situation is one in which the company has set up no training department. In such a case, if uniform procedure in public-contact training is to be carried on effectively, a staff man or executive high enough in the company organization to command recognition should be made responsible for promoting and prompting the training activities. In this situation every line department must carry on its training activities. Much time and expense will be saved in such a case, if a staff man can be assigned to follow through with the work analysis, preparation of training material, and at least with the introduction of the training program.

Regardless of which of the three situations exists in the company wishing to inaugurate public-contact training, there are two procedures which may be followed in analyzing the work. In the first, a complete survey is made of the contact jobs. The work is broken down and completely analyzed for the contact difficulties. The solution of these difficulties is developed and suitable corrective methods are selected by the training staff consulting, as necessary, with the line organization. With this information as a basis, the company training program may be prepared.

The second method consists of making a general survey of the contact jobs. From this survey the possible difficulties are classified as to general type. An outline is then prepared, and all of the contact employes are called in in small groups to discuss their jobs for the purpose of bringing to light the difficulties and appropriate remedies. The principal advantage claimed for this method is that the contact employes feel that they have helped to analyze their work, and have contributed to the solution of the difficulties and to the establishment of the standard methods adopted. The training and analysis are combined, and time is saved in getting the ideas across to the employes.

Some contend that public-contact training is only a phase of job training and should be included in the job-training program. The analysis should then cover all phases of the job, and the training material should be set up so as to supply all of the information that the employe must have to properly function in the contact position. It is claimed that this method will tend to establish the personal service elements of a contact job as a definite part of the job requirements, in the minds of both the contact employe and his supervisor.

Others who have studied the situation feel that public-contact training should be separated from other phases of training. They feel that only by such separation can sufficient stress be placed on the importance of the personal service elements of public-contact jobs. Another advantage claimed for such separation is that it helps the public-contact training to go ahead with more dispatch than would be possible if it were combined with other phases of job training. They feel that the analysis should be made separately, and the initial training program carried through, and then on follow-up, the public-contact training can be made a part of the complete job-training program.

The suggested possible methods are by no means all that might be applied. A combination of methods which results in a compromise between the two extremes might be used effectively. In any case, however, a definite program should be worked out and followed through.

NECESSARY ELEMENTS OF A TRAINING PROGRAM

In this report an attempt has been made to analyze the public-contact jobs of the average utility. It has been found that they may be divided according to the personal requirements of the holders of the job; according to whether they are non-supervisory or supervisory; according to the location of the contact; according to the nature of the contact itself; and, finally, according to their classification as to the character and importance of the personal contact phases of the work.

It should be noted that the general analysis of jobs, preceding the preparation of training material for the holders of public-contact jobs, is the same as that preceding the preparation of any other training material. The only difference is that the study is made with particular emphasis on the public-relations aspects of the work.

As indicated before, no public relations training program can be effectively carried out for any class of work which has not first been analyzed as to the necessary traits for those who handle it. A blanket training program, broad enough to cover all contact jobs, would be so broad as to be of little use for any particular contact job. Similarly, any training program which would be properly adapted to one type of work would not be fitted for another, except within the general limits indicated in the various groups, and within the group it would apply only to those factors which are common to all lines of work within the group.

No attempt has been made in this report to analyze in any detail the work of any particular job, except that of the bill-deliverer. Even in the case of the bill-deliverer's work, the brief analysis in this report, which is not complete, would not be sufficient for any one company. Each company must study its own situation, and make sure that every detail of the contact phases of the work has been considered.

The next report will deal with the preparation of training material and the building of a training program based on the facts and requirements brought to light by an analysis of the public-contact elements of the work.

TRAINING FOR BETTER PUBLIC CONTACT—III BUILDING AND CONDUCTING THE TRAINING PROGRAM

INTRODUCTION

In the preceding report of this series (Training for Better Public Contact—Analysis of Public-Contact Work, Publication No. 289-44) are listed, under the heading "Methods of Analyzing Personal-Service Elements of Public-Contact Jobs," a variety of methods which may be used both for analyzing jobs and for setting up training material for use. The latter part of the report was intended as an introduction to the discussion of the preparation of training materials.

Methods of Conducting Training Program

There are many possible methods of carrying on public-contact training. In this discussion only three methods will be presented for the reason that this number will suffice to illustrate the principles and the problems to be encountered. Unless otherwise stated, the term "training" will refer to public-contact training.

First Method

Under the first method the training program is planned and conducted entirely by the training department, or, in a smaller organization, by the staff employe who is responsible for training activities.

Second Method

The second method is one in which the training program is carried on by the supervisors and executives of the various departments in which training is carried on, while the training department or staff training man cooperates with the line organization and functionally directs the training activities.

Third Method

In the third method the training program is planned by the training department or staff training man with the assistance of the department supervisors and executives, but is conducted in the initial training period by the training staff man, with subsequent follow-up and retraining handled by the department with the assistance and advice of the staff training man or men.

The advantages and disadvantages of these methods will be discussed on the basis of the experience and observation of those who have used one or more of the methods.

Before the analysis of the jobs is begun, it is necessary to decide which method of presentation is to be employed, as both the method of making the analysis and of preparing the training material will be influenced by the method of presentation.

The survey (Training for Better Public Contact—Its Necessity and Importance, Publication No. 278-52) indicated that the methods of presentation may include the use of lectures, printed text material, classroom recitations, group conferences or discussion meetings, printed rules and regulations, bulletins and circulars. These may be grouped into two general methods: "Conference" and "Instruction." The determination of which method is to be used may depend upon the experience of the employes involved. Employes of many years' experience do not readily accept or welcome instructions upon points on which they feel that they themselves are authorities.

On the other hand, they are generally willing and anxious to participate in conferences for the discussion and solution of problems when they feel that because of their experience they can help in the shaping of improved plans. When a new employe is hired, however, little can be gained by using the conference method with him, as he is unacquainted with the problems which are to confront him in his new position. He needs and expects instruction in some of its various forms. Similarly, when consideration is being given to putting into effect a new routine or procedure, the experienced employes may contribute valuable suggestions if they are called into conference. When the procedure is agreed upon, however, it must be described in clear, sufficiently detailed instructions.

Analysis of Public-Contact Jobs and Preparation of Training Material

Analysis of the public-contact phases of the work must be made first. As already indicated, one method is to make a complete survey of all jobs involving public contact, to develop a solution to public-contact difficulties, and to select suitable corrective methods, with this work being done by the training staff in consultation with the line organization. Another suggested method is the making of a general survey of contact jobs. with a classification of the difficulties as to general types only, followed by the preparation of a discussion outline. This outline then can form the basis for discussion in group meetings with the line employes for the discovery of the detailed difficulties and the development of appropriate remedies.

In either case the discovery of difficulties and the development of remedies is the underlying purpose of the analysis. Where the first method is used, the training staff retains virtual control of the analysis and attempts to develop, following consultation with the line department, the methods which should be used to solve the difficulties. The advantage of this method is claimed to be the greater speed with which the work can be done.

One of the outstanding advantages claimed for the other method, where the training staff merely develops a discussion outline based on a preliminary survey and then uses this outline as the basis of meetings in which all employes take part, is that

---

Pub. No. 289-83, Serial Report, Industrial Relations Committee.

these meetings themselves virtually become the first step in the training process. The act of analyzing the jobs, of locating the difficulties, of determining the appropriate solutions to them, and of discussing the best methods of putting the solutions into effect, is felt by many to be the foundation of the training program and an important integral part of the actual training.

Either method may be used when either the training staff is charged with the responsibility for the training program, or when the line department is charged with this responsibility.

The preparation of the training material may depend upon whether the particular difficulties to be solved are general for all public-contact positions, or whether they are peculiar to a few. As already mentioned, the basic factor of courtesy should enter into all personal contacts, whether face-to-face, by telephone, or by correspondence. However, the determination as to how a meter-reader shall answer particular questions relating to the meter when they are asked by a housewife is of immediate interest only to the meter-reading group.

General manuals may be prepared covering the common features for each of the three types of public contact. These may be, roughly, of the nature of materials suitable for handing to all new employes who are to be placed in public-contact positions. This training material could include general information regarding the company's business and its policies in relation to public-contact problems. The preparation of training material applied to specific positions, however, must include the various difficulties peculiar to these positions, and the approved solutions for them.

As already stated there is a very definite use for discussion groups for certain types of training. Regardless of who is responsible for the collection and preparation of training material, one method which has been found useful is the division of the employes within a given department into small discussion groups for the purpose of making the analysis. The leader of each group, whether he is a training staff man or a departmental staff man or supervisor, follows a general outline covering the various public-contact phases of the work of the particular division under discussion. An attempt is made to list all of the difficulties with which the workers are confronted. Frequently, of course, merely bringing these difficulties to light indicates methods by which they may be eliminated. Other difficulties, however, such as the answering of questions or complaints based on rates or service, must be considered and suitable answers agreed upon. For example, a question which all receiving tellers hear every day is, "Why is my bill so high?" A satisfactory answer should be prepared and directions given as to what action should be taken if the answer does not satisfy the customer.

It must be borne in mind in the preparation of any training material that it is directed to two general groups: One is the present employes, and the other is the new employes as they enter the company, or as they enter upon a new type of work requiring contact training. Training material then must be set up in such a way as to be readily usable in training new employes.

General Contact-Training Objectives

The purpose of general contact training is to convey to each contact employe and to his supervisor the idea that only the contact employe can carry out the company's responsibility to the customer and the public in personalizing the company's service to the public. To say to the contact employe, however, "You must accept this responsibility," without going into the details of what is included in the personal elements of his job, will not insure uniformity throughout the organization in establishing a high standard of service along this line.

All public-contact training has as its essential object the development of methods and technique of permanently satisfying the needs and wishes of the customers. The experience of a number of companies indicates that the employe's responsibility in this matter can be broken up into the following items for consideration in the training program:

Appearance
Politeness
Speech
Information-Giving
Interest in the Customer.

All of these factors are involved in every face-to-face contact. All except appearance are involved in telephone contact, and all except appearance and vocal speech are involved in correspondence with the customers.

Since this is true, general public-contact instruction material can be prepared on all these factors and made available for distribution to every new employe hired for a public-contact position. In the subject of "Appearance," the care of the person and proper grooming, in addition to maintenance of business-like working conditions, can be indicated. Under the general subject of "Politeness," specific words and acts, which are or are not polite, can be listed and the indication drawn as to which should be used. Under "Speech," the use of proper tone, enunciation, pronunciation and choice of words can be developed. Under "Information-Giving" the importance of completeness, clearness and accuracy in making statements can be shown. Under "Interest in the Customer," the general devices which show immediately the employe's desire to satisfy the wishes and interests of the customer can be pointed out.

Application of Selected Method to a Specific Job

In the discussion of the application of training methods to a specific job, it will be assumed that the training program is planned initially to train an existing personnel. The material developed will be used to train new employes as they enter, but its initial purpose is to get the existing personnel to adopt uniform satisfactory methods in carrying on the personal service elements of the public-contact work.

In order that the differences in the three methods may be clearly set forth, a specific job has been selected. The work of the inside repairman or service man who answers the customer's request for help in case of trouble with wiring or appliances on customer's premises, is a job common to all companies, regardless of size. This job will be analyzed as to the public-contact problems. The methods of setting up training material will be set forth, and the method of training will be outlined under each of the three methods.

Since the initial purpose of the training is to establish improved standards of personal service to the customer, the program will be conducted by the small-group conference method. In addition, the procedure involved in presenting this material by the instructional method will be outlined. It will be assumed that previous agreement had already been reached between the department concerned and the training department providing for training work to be done in the department.

TRAINING DEPARTMENT OR STAFF CONDUCTS TRAINING

Preparation of Preliminary Outline for Analysis

When decision has been made to carry on public-contact training for the specific job in question, and the department head has requested the training department or the staff training man to prepare and conduct the training program, the training man should set about bringing to light the contact problems peculiar to the job in question. As the first step in this procedure, he should prepare an outline to be used in the work analysis of the job. In setting up this outline, the general analysis of contact jobs, as presented in the preceding report, may be used as a guide, and the outline might take on the following form:

Nature of Responsibility: Is it supervisory or non-supervisory?
Nature of Contact: Is the contact face-to-face, by telephone, or by correspondence?
Location of Contact: Is the contact on customer's or company's premises?
Classification of Contacts: Is it likely to be a pleasant or unpleasant contact?
    Are the personal contacts an incidental or a major part of the work?
    Does the nature of the work require technical or mechanical skill?
Personal Requirements: What special traits and physical characteristics are necessary for holders of this contact position?
    Is personal appearance of importance to the holder of this job?

Consultation With the Department Head

When the training man has prepared his outline, and if he is not familiar with all details of the job, and even if he is familiar, it will be good policy to solicit the aid of the department head so as to insure his interest at this point. He will, therefore, in consultation with the department head or with the sub-executive or supervisors designated by the department head, go over the outline carefully step by step. In consulting with the department head or departmental supervisors, the training staff man, using the preliminary outline as a guide, will find, in the case of the inside repairman or service man:

That, in general, the work is non-supervisory, although the man may have one or more employes assigned to help him on some jobs.

That, in general, the contacts with the public are, face-to-face, although, occasionally and incidentally, they may be by telephone and almost never by correspondence.

That the contacts are usually on the customer's premises or in the public thoroughfares, and almost never on company property.

That, in general, although the customer is likely to be irritated by the interruption to his or her service, the customer is glad to see the repairman who comes to remedy a difficulty.

That, because of the nature of the work, the personal service elements of the job are of primary importance.

That the nature of the work requires expert, mechanical skill, without which the employe cannot be effective as a service man.

That, because of the mechanical nature of the work, the employe must have the full use of his hands and should not be handicapped by other deformities.

That the employes must be tactful and alert so as to be able to serve and not offend the customer.

And, finally, that since the employe is representing the company in the customer's home or place of business, his general appearance should be, in keeping with his work, neat and businesslike.

Preparation of Discussion Outlines

Classifying Nature of Contact Job

From the information collected by consulting with the line organization, the staff training man can readily determine which of the fundamentals should be stressed in the training material for the job of the service man.

Appearance plays an important part, because the employe is the representative of the company, and most of his contacts with the customers are in their homes or places of business.

Politeness also plays an important part in making a good impression on the customers for the reason that the contacts in this particular contact job are principally face-to-face.

Speech is also important, and should be dwelt upon in the training program.

Many questions regarding appliances and service facilities in general will be asked, and, therefore, this contact employe must be prepared to answer all reasonable questions.

Since the contacts are face-to-face and involve personal discourse with the customers on a variety of subjects, "Interest in the Customer" should also be stressed.

Thus, it appears that in the detailed study of the service man's job, in the small group discussion meetings, it will be necessary to dwell on each of the five fundamentals which have a bearing on the creation and maintenance of satisfactory public relations.

Setting Up the Discussion Outlines and Conducting the Discussion Meetings

Here, again, although the training man may be intimately acquainted with many or all of the details of the service man's job, it will be well for him to work closely with the department supervisors in the preparation of the discussion outlines.

The aim of the training program should be to develop in the service man the desire and ability to make a satisfactory final impression on the customer in each contact that he makes. Although each of the five major factors which have been listed is found to have a bearing on this man's work, all of them are a part of the basic factor which underlies all of the work—the good final impression on the customer.

Since this is true, a consideration of this over-all aim forms the logical introduction to any series of training meetings. In setting up the outline for a consideration of the final impression desired and the means of producing it, the relative part played by each of the five factors can be developed.

1. Final Impression

Having determined from the analysis of the job the factors which should be considered in the training program, the training staff man will prepare an outline to be used as a guide in his meeting with the supervisors in the department. In this meeting with the supervisors, he will first outline the purposes of the training program which are: To discover the difficulties involved in the job of the service man, to discover solutions or remedies for these difficulties, to obtain approval or acceptance of these solutions, to compile in logical order in appropriate groupings the approved procedures, and, finally, to follow up and re-train in line with the adopted procedures.

Then the staff man will point out to the supervisors that, since the service man's job is a face-to-face contact job, all of the factors should enter into the training program. He will start with appearance and will ask, "Has appearance any effect on establishing a good impression on the customer? If so, what factors enter?" The discussion following will develop the fact that appearance is a decided factor, and some of the points that will probably be raised are that the clothing should be appropriate and as clean as is possible, and many other similar items out of which can readily be drawn the conclusion that evidence of attention to clothing and person is a decided factor in the final impression made on the customer.

The training man will then proceed to the subject of politeness, and to his general question as to whether politeness is important, he will get an assenting answer. Then, to his question as to what constitutes politeness in the job of the service man, he should be able to bring out information that will indicate that politeness is shown by speech, facial expression and personal acts, and, finally, reach the conclusion that politeness is expressed by acts and language, and plays an important part in establishing a good final impression.

The training man will then attempt to find a way in which speech influences the customers' feelings. In discussing this, the choice of words used, the tone of voice and the distinctness of the speech will be found to have a bearing. The training man will then try to find out how information-giving affects the impression which the customer receives. It will probably be brought out that some of the essentials are understanding what the customer wishes to know and then answering the customer's question understandably, and finally it will be developed that in order to meet the other four requirements the service man must be interested in the customer and his problems. Then the training man should attempt to develop at least a general idea of the items which will have a bearing on the final impression and which are not covered by the five major factors. The purpose of this first conference with the supervisors is to sell the supervisors on the methods to be used with the contact employes when they are called in for group conference, and to make them familiar with the material before it is presented to the service men. This will insure their cooperation in the problem as to procedures, and it will also give the training man information and material which he can use in preparing a similar, but more detailed, outline for his meetings with the service men on the subject of final impression.

The training staff man will have added to his own information the ideas of the supervisors as to the means which the service men should employ in creating the best final impression on the customer. He will also have obtained their suggestions as to particular subjects which they feel should be discussed in the meetings of the training man and the service men. When this material has been classified and arranged in logical order, the training staff man will be prepared to hold his first meeting with the service men.

In the first meeting with these men, essentially the same situation and problems will be met as in the first meeting with the supervisors. The purposes will be to acquaint the service men with the proposed procedure and to outline to them the desire to obtain a complete list of the difficulties confronting them, the solutions to these difficulties, and an essential agreement upon the most acceptable solutions. In this meeting, also, the training man will prepare the transition to the following meeting by developing the idea that appearance is one of the most important factors in producing good final impressions.

Throughout the entire series of meetings, essentially the same plan, that is, discussing the factor with the supervisors first and with the service men second, is carried out. Since this is true, it will not be necessary to outline separately the meetings with the supervisors and with the service men on each topic. In each case the staff man uses the supervisors' meeting as the place to crystallize his plans, to secure illustrations and additional suggested questions, and to study the fundamentals of the tentative discussion outline which he has prepared. Also, the supervisors are familiarized in advance with the subjects which the service men are to discuss and can anticipate questions from their men relating to these subjects. The staff man uses the same basic outline, with the service men, which he used with the supervisors, modified by such changes and enlarged by such additions as his meetings with the supervisors indicate are necessary. These additions are chiefly in the form of questions suggested by the discussion with the supervisors.

2. Appearance

As previously indicated, the first major factor to be discussed following final impression is appearance. In this meeting, the staff man aims to learn what is considered to be appropriate or inappropriate in appearance from the viewpoint of the service man on his job. He may start the discussion meeting by asking, "What things about the service man's appearance create the best or worst impression on the customers?" "Which does the customer observe more closely, appearance of the person or of the clothing?" "Just exactly what kind of clothing is appropriate for the service man to wear on the job?" "What are the minimum requirements as to attention to personal appearance by the service man?" "What defects in personal appearance should the service man be most careful to avoid?" "What personal habits which the customers can observe are most likely to annoy them?"

From the answers to these and many other associated questions the staff man should obtain a comprehensive description of what the appearance of the service man should be. This will probably range from a cleanly-shaven face to the wearing of a necktie. In discussing this subject, just as in all the others, the staff man must be careful not to include anything in the list simply because it "sounds well," but which, experience has shown, will not be adhered to. It should be borne in mind that the company cannot run entirely counter to the community or current fads or fashions with regard to clothing. He must include only those qualifications and characteristics to which there is essential agreement.

In discussing habits, while still thinking of the service man's appearance, the question of politeness will undoubtedly arise. This can form a natural transition to the following subject, which will be politeness.

3. Politeness

In the next group of meetings the aim of the staff man is to learn exactly what polite acts and phrases the service men and their supervisors feel are desirable. Perhaps the first and most obvious question for discussion is, "How do you greet the customer, and what do you do and say on leaving the customer?" Other questions which should prompt discussion and lead to definite conclusions include: "What are the most obvious ways a service man can show that he is polite?" "What are some of the polite expressions commonly used?" "How will the customer judge whether or not the service man is polite?" "Must the service man always smile in order to be polite?"

So far, all of the questions have dealt with formal politeness. Distinction must be made between formal politeness and genuine courtesy, which involves a mental attitude in addition to the simply formal polite act or expression. Questions which emphasize this difference might be, "What is the difference between tact and politeness?" and "Can a person be polite without being courteous?" Discussion of these and related questions will bring out definitely the need for much more than formal politeness. This added factor, called for convenience "Interest in the Customer," will be discussed later. In the discussion of politeness, the use of certain words and phrases is dealt with at length. This makes an easy transition to the following subject, which is speech.

4. Speech

In dealing with the effect of speech in creating a lasting favorable impression on the part of the customer, many concrete situations can be developed. An obvious subject, too, with which to begin the discussion, is tone of voice, as the tone used by the service man in answer to the housewife's question of "Who is there?" is likely to determine her reaction to the entire situation which follows. The question, "What is there about the tone of voice of other people that you like?" easily opens up a general discussion of voice. The question, "Why do telephone companies train their operators to develop 'The Voice with a Smile'?" ties in closely with this situation. The question, "What tone of voice should be used in speaking to an angry customer?" will force further concrete discussion. This can naturally lead to the question of distinctness in speech. A hypothetical illustration showing the misinterpretation that can come from indistinct sentences would fit in well here. The question, "How can a service man be sure that he keeps his voice distinct?" should develop the idea that he should avoid mumbling, should speak slowly, should avoid slurring his words and should watch the customer's expression to see whether she understands what he is talking about.

Another vital point about speech in which every service man is interested is the choice of words, including the good or bad effect of the use of slang and of technical words and phrases. The question may be asked, "Should slang ever be used?" followed by other questions such as, "Should slang be used to give the customer the impression of greater friendliness?" The question of the use of technical words could be approached by asking a service man to give, in his own words, the answer to various questions which the customers ask him. In the answers, the service men will undoubtedly use expressions with which the customers are not familiar or do not understand. Frequently it will be discovered that certain words may be called "company slang" in that they have a definite meaning within the department or the company; but mean nothing to the outsider. It will be easy for the service man to understand how the answer to the question, "What is the matter with my iron?" "Oh, your element is out of order," would probably not mean much to most housewives. Similarly, saying, "Your contacts are burned," would not be helpful in satisfying the average customer's curiosity. A request for a list of frequently used terms with which customers may not be familiar, paralleled by a simple explanation which can be understood, should be made at this time. This later discussion will lead naturally into a consideration of the general method of giving information to customers. This can follow as the subject of the next meeting.

5. Information-Giving

"Which is most important, to use correct grammar or to give correct information?" "What is the worst case of trouble you have ever known caused by a service man giving poor information?" "What is poor information?" "How do you know whether or not the customer understands your answer?" "What may be the result if the information given is not complete, or not accurate, or not clear?"

The service men should be asked to give a list of the questions they are asked most frequently and the answers which they give to the customers on these questions. A discussion of these answers and of the answers to the questions preceding, and others relating to them, should bring out clearly the extent to which the information which is given and the way in which it is given influences the customer's final impression. Throughout the meetings concerning information-giving, and, in fact, in most of those preceding, allusions to the service man's attitude toward the customer will be mentioned as important. When speaking of information, the fact that the interested service man will ask additional questions to be sure he knows exactly what the customer wishes, and the fact that the interested service man will be especially careful to give information which will satisfy the customer, will lead naturally to a discussion of this factor called "Interest in the Customer."

6. Interest in the Customer

The discussion of the ways in which interest may be shown and what is important in creating the final impression on the customer should naturally round out the general discussion of public-contact problems. "Is doing a good repair job the only evidence of interest in the customer which the service man can show?" "Does the customer expect any more than this?" "State certain ways in which the service man can show his interest in the customer, that is, his desire to satisfy the customer's needs and wishes." Presentation of a specific situation and an analysis of what should be done, as in the case of an electric fan which has ceased to work on a hot day, should develop specific ideas on this point. Questions may be asked which will indicate the importance of the initial approach to the customer, the necessity for listening to the customer's story, the desire to remain open-minded in the face of criticism, and the need for showing friendliness, without being familiar, throughout the situation. The discussion of the necessity for maintaining a friendly attitude should be carried to the extent of stressing the point that even in situations where the employe must be firm, the appearance of friendliness can be maintained.

The outcome of the consideration of interest in the customer should have shown clearly the paramount importance of this factor in creating good final impressions.

7. General Comment

The placing of the material discussed under the five factors is arbitrary. It will be found, of course, that many subjects will be discussed from almost as many angles as there are factors. This is desirable, as it serves to place additional emphasis on such points. An example is the case of choice of words to use. In this discussion, this was placed under speech, but it would obviously also be discussed from the related angle of politeness, information-giving, and interest in the customer.

The advantage claimed for this plan is that it cuts down the length of time required to inaugurate and conduct the training program by having a training expert in charge of the program in all of its details from beginning to end. A disadvantage claimed is that it takes away one of the outstanding responsibilities of the line organization, namely, the normal responsibility for training.

Standards of Personal Service

As already indicated, the underlying reason for the training program is the acceptance and establishment of improved Standards of Personal Service. As outlined, the aim of the staff man is: First, to learn the difficulties; second, the solutions to them, and, third, to secure the acceptance of those solutions which should be used as a guide. The aim of the meetings is two-fold: To arouse immediate appreciation of the problem of how to satisfy the customer best, and, to codify the accepted standards. Throughout the entire series of meetings, both with the supervisors and with the service men, careful notes must be taken as to the material which will later be set up as the Standards of Personal Service for the service men. This is the material which, after approval by the department head and after its dissemination throughout the department, will not only be the guide and reference book for existing personnel, but will also be the basis upon which new service men shall be trained.

The next step is to set up in easy, usable form the training material which has been developed.

The form of the Standards of Personal Service naturally will vary. Direct statements, a narrative, or questions and answers may be used. The present trend of thought seems to favor the latter method. Although some training material is written in the second and third person, since the desire is to emphasize the service man's own contribution to the development of the personal service manual, the use of the first person, as far as possible, is preferable.

To illustrate, in the material which may be developed in the sections devoted to final impression and appearance, such items as the following will be included:

(1) **STANDARDS OF PERSONAL SERVICE**
"Service" Department
Leaving a Good Final Impression with Customers

(Selected by service men and supervisors from ideas and devices proposed and discussed by them in their group meetings.)

1. What are the five elements that cause the customer to have a friendly feeling toward the company?
   (1) "Appearance"; evidence of attention to my clothing and person.
   (2) "Politeness"; good manners expressed by my acts or language.
   (3) "Speech"; the impression given by my words and tone of voice.
   (4) "Information-giving"; explanations that will completely satisfy my customer.
   (5) "Interest in Customer"; a real cordial and sincere interest in my customer's wants.
2. How may I produce a poor Final Impression on the customer without realizing it?
   (1) By talking too much.
   (2) By ignoring customer's remarks as of little importance.
   (3) By losing interest in my customer.
   (4) By failure to give a greeting or leave-taking.
3. What is a good aim to set for myself as a representative of the Service Department?
   I will cause the customers to feel more friendly toward the company through my work, actions and speech.

(2) **STANDARDS OF PERSONAL SERVICE**
"Service" Department
Presenting a Pleasing Appearance

(Selected by service men and supervisors from ideas and devices proposed and discussed by them in their group meetings.)

1. What points in clothing must I observe to make a good appearance?
   (1) The coat, trousers and shirt should be conservative in color and kept in as neat and clean a condition as is possible.
   (2) The shoes should be in good repair and cleaned or polished.
   (3) A conservatively colored tie, knotted neatly, should be worn at all times.
   (4) The hat or cap should be clean and appropriate for the work.
2. What are the minimum requirements of one's person for making a good appearance?
   I should at least:
      (1) Keep hair cut and combed;
      (2) Keep hands and face as clean as possible;
      (3) Shave daily, if necessary;
      (4) Keep teeth and breath clean;
      (5) Stand up straight and look alive.
3. What things should I avoid doing to make a good appearance?
   (1) Chewing anything while with a customer.
   (2) Using tobacco on customer's premises.
   (3) Wearing jewelry prominently or badges which have no relation to the work.
   (4) Indulging in any annoying habits, such as humming or whistling.

The above examples of typical Standards of Personal Service might not apply in every detail to every organization. They should serve as an illustration of the finished material which is used for reference by present service men and for training new service men.

Follow-Up

General experience indicates that much of the advantage gained by an initial series of meetings for public-contact training disappears in a short time unless some uniform follow-up procedure is maintained. The purposes of the follow-up meetings are to maintain the interest of the service men and their supervisors in customer-relations problems, and, further, to arrive at solutions to new problems as they arise. Such problems may be the result of changes in policy, changes in rates, changes in procedure, or from a variety of other factors.

In the follow-up meetings, which, as in the case of the initial meetings, are held both with supervisors and with service men, current reports of service, complaints, letters of commendation, and other items of information should be drawn upon extensively to keep the discussion up to the minute. If the report of a professional service sampler, either on the payroll of the company or retained by the company, indicates that the actual performance of the service man was not in accordance with the agreed Standards of Personal Service, this should be discussed in the meeting, to determine whether the standards need revision or whether the service man was simply not doing what had been agreed to. As new situations arise, changes in and additions to the Standards of Personal Service should be made. Representatives of departments with which the "Service" Department has most frequent dealings should be asked to attend follow-up meetings in order to minimize such difficulties as may be due to misunderstandings as to procedure or departmental policies.

DEPARTMENTAL SUPERVISORS AND EXECUTIVES CONDUCT TRAINING

Under this plan the training program, from the original analysis of the work through the follow-up meetings, is carried on by the executives and supervisors of the department concerned, with the cooperation of the Training Department or staff training man who functionally directs the training activities. Rather than outlining this entire procedure in the same minute detail as was done in the plan just described where the Training Department conducts the training, that plan will be used as a basis of comparison, and the second plan will be described by outlining the points in which it differs from the first plan.

The same list of general questions, covering nature of responsibility, nature of contact, location of contact, classification of contacts and personal requirements, must be prepared and applied. The preparation would probably be by the training man, but the application of the questions to the service man's job would be made by the department itself.

In classifying the nature of the contact job, the line organization can readily determine, from the information it collects, which of the fundamentals should be stressed. These factors, suggested by the training staff man—appearance, politeness, speech, information-giving and personal interest—will, of course, be the same as those in the first plan.

In this plan, as in the first, discussion outlines must be set up, beginning with the one on the subject of how to make a satisfactory final impression on the customer, and going on through the list. The staff training man should work closely with the department in the preparation of these outlines. He should consider them particularly from the standpoint of organization set-up, as related to their usableness as training materials. Since he is interested in the technique of training more than in the subject matter, under this plan he must know first what the general objectives of the departmental training program are, and, with those in mind, aid in framing the material so that it will lead to that result.

In the preparation of this material the training man would, of course, work chiefly with the departmental executive responsible for the training in the "Service" Department. He would also advise him materially in the techniques involved in handling training meetings with the supervisors. He would, further, similarly coach the supervisors, who, under the second plan, would be the ones to hold the training meetings with the service men. All of this would apply both to the original training and follow-up training.

The outstanding advantage claimed for this plan is that it keeps the responsibility for training in the hands of the line organization and emphasizes the fact that training is an important phase of supervisory responsibility. A disadvantage claimed is that it takes much longer than the first plan because of the length of time required to properly train line executives and supervisors to hold effective training discussion meetings. There are some who feel that the supervisors never can be expected to train effectively.

INITIAL TRAINING BY TRAINING MAN AND FOLLOW-UP BY SUPERVISORS

Under this plan exactly the same procedure as outlined under the first plan is followed through the entire initial series of meetings, covering the preparation of the training material, the conduct of the training program, and preparation of the Standards of Personal Service. The training man, knowing that he is to turn over the follow-up training to the line organization, would, however, be discussing training methods and techniques with the department executives and supervisors as he proceeds. After the initial training program is completed and the Standards of Personal Service have been compiled, the training man would then devote his attention to meetings with the supervisors to prepare them for the follow-up training. Before the first and several following meetings, which any supervisor was to hold with his service men, the training man would outline in detail the material to be discussed in the meetings. He would add such supplementary suggestions as were advisable to aid the supervisor in knowing when to do various things during the course of the meetings. He would also coach the supervisor as thoroughly as possible in the various techniques of conference leading.

The training man would sit in at the first few meetings, acting chiefly as an observer, but also to be in readiness to add tactfully a question now and then if necessary to aid the supervisor in getting himself established in this new type of work. After each meeting he would also discuss the results with the supervisor, in order to point out ways in which difficulties which arose could be avoided in future meetings.

As the training programs proceed, the training man will turn over more and more of the work to the supervisor, until finally the supervisor should be preparing the material and conducting the meetings with only occasional consulting service from the training man. As outlined under the discussion of follow-up under the first plan, the training man should continue, however, to furnish the supervisor with such material as may be obtained from current reports of service, complaints, letters of commendation and other items of information.

The first advantage claimed for this plan is that it cuts down the length of time required to inaugurate and conduct the initial training program by having the training expert in charge of the program in all of its details. The second advantage claimed is that it provides for the eventual return of responsibility for training to the line organization. It does this, however, after the line organization executives and supervisors have had an opportunity to become acquainted with the training methods involved and are, therefore, in a better position to conduct the training program effectively.

CONFERENCE MANAGEMENT AND TECHNIQUES

Most of the following material is that which the trainer would give to the supervisor who holds the meetings. It is assumed that the trainer himself would be familiar with these techniques and methods. Some of it applies to all three methods and is, therefore, included under one heading so as to avoid repetition.

Number of Meetings

The first thing to be determined is the number of meetings required for the initial training program. Experience has indicated that from eight to twelve meetings are required, depending on the group involved and the relative amount of emphasis required on particular factors. In the case of the service men ten meetings should be sufficient to cover the initial program.

A single discussion meeting should probably be sufficient to introduce the whole program, and while probably one meeting should be sufficient to develop the fundamental ideas on appearance, it may be necessary to devote two meetings to this and then save sufficient time in the following meetings, so that ample attention can be given to the item of information-giving, which, in the case of the service man, covers such a broad field that more time will probably be necessary in order to develop all of the ideas.

The conference leader must develop at an early stage the ability to determine when the members of the discussion group have come to an agreement and are ready to accept the ideas which have been developed. In order to accomplish this, he must be able to get all members of the group to participate, so that he can judge whether or not they have assimilated the results of the discussion.

Time of Meetings

Since the purpose of these meetings is to improve the service to customers, and since the personal service element is a definite part of the service man's job, this is a phase of job training and is a part of management's responsibility and, therefore, the meetings should be conducted on company time if it is possible to do so. In situations where the service men cannot be called together during the regular working hours, evening meetings would be necessary. All service men should be required to attend the meetings, and attendance should be considered the same as any duty performed after regular working hours.

Length of Meetings

The length of the discussion meeting is another important point. Experience has indicated that people who are not accustomed in their regular work to participate in creative discussion are not able to maintain enthusiastic interest for a period of much more than one hour and certainly not in excess of one and one-half hours. Since the success of this method of training depends upon the enthusiasm of those participating, it has been considered good practice to limit the meetings to one hour, and to arrange the outline sufficiently in detail to keep the discussion active during this period.

Number of Men in the Groups

Since it is essential that every service man in the group participate in the meeting, it is necessary that the number be small enough so that this will be facilitated, both from the standpoint of time involved and the standpoint of close relationship between the leader and the small group, which is not possible in a larger group. Fifteen men is probably the maximum number where general participation is desired, and groups as small as six can operate successfully. However, ten to twelve probably is the best-sized group for discussion meetings.

Physical Situation and Materials

Since the group members are not accustomed to concentrating on discussion of this sort, it is necessary to reduce artificial interference to a minimum and to make the physical situation as conducive as possible to quiet, uninterrupted discussion. The room chosen should be sufficiently isolated so that the meeting will not be interrupted by people coming in and out, or by the telephone ringing, or by the roar of machinery. Sufficient chairs, a table upon which papers can be placed and around which all of the members can sit, scratch paper and pencils, a blackboard on which the leader can make notes and draw diagrams, and such special tools as are necessary should always be on hand before the meeting opens. The room should also be well ventilated and well lighted.

Since the purpose of the meeting is to arrive at accepted Standards of Personal Service, a recording secretary should be appointed. The secretary should keep a careful record of the ideas developed, and especially of those points upon which agreement is reached, and also those points upon which it is felt further discussion should be had at a later date after more time and thought have been given and more information has been developed.

There are some disadvantages in appointing a secretary, in that it may make some members of the group hesitant to enter into the discussion for fear that their statements may be taken verbatim. This can readily be dispelled by a statement that reference to source of ideas will not be made in deciding on the standards to be followed. However, if the leader is proficient in taking abbreviated notes which are sufficient for him to sum up and bring the discussion to a decision, and to compile the Standards of Personal Service, it will not be necessary to appoint a secretary. Some leaders feel that this is preferable.

Conduct of Meeting

The first thing in the first meeting in which the supervisor acts as the conference leader is for him immediately to get the group and himself in a comfortable state of mind. Since the usual working relation is that of supervisor and subordinate, this feeling must be overcome by the attitude which the supervisor assumes from the start. Some such statement as "We are beginning today a series of meetings in which we are going to discuss many of our common problems in order to decide on the best solutions to them, and we cannot be sure that we get the best solutions unless each of us contributes from the ideas gained by experience with these problems. Then when we have collected all of the ideas, we can readily select those which we agree are the best and most workable." He should follow this immediately by a question which will provoke thought and arouse immediate discussion. In the case of the service men, the question, "Is the quality of the repair which you make the only thing which goes to produce a good or bad impression on the customer?" might be asked. The immediate answer will be "No." This will be followed then by the question, "What other things influence the customer?" From this point on the supervisor's function is to follow his outline, which includes many questions previously prepared, and to insert such additional questions as are necessary to stimulate further discussion; or, when the discussion seems to have gone far enough, to lead to a final decision as to what the best practice should be in the various factors that should be considered in the discussion of final impression.

The supervisor must develop, at an early stage, the ability to distinguish between a thought-provoking question and one that will terminate a discussion by a "yes" or "no" answer. The first question used was answered by "no," but the following question immediately opened the field of discussion. By further thought-provoking questions, the supervisor can complete the discussion in line with the outline. He should learn that at the proper time, when agreement seems to be reached, appropriate deciding questions should be asked to which "yes" and "no" answers will be obtained.

Devices

Many devices may be used to stimulate interest by illustrating actual situations or by demonstrating through contact the necessity for establishing standardized ideas and methods. Among those devices may be included a set of a number of suggested methods from which each member of the group is to select the most desirable. This device is especially useful in arriving at a decision as to the best method to be selected from those which have been suggested.

Dialogues illustrating concrete situations in the service man's daily work can be prepared preceding the meeting and handed out to certain men who will simulate respectively the customer and the service man. If one dialogue illustrates the wrong way of meeting the situation and the other the right way, they can form an excellent basis of comparison and for discussion.

In order to crystallize the conclusions during the progress of the meeting, and particularly near its close, in order to indicate the progress which has been made, the leader must summarize from time to time. In addition to this, the leader should give a definite indication of the subject which will be discussed in the following meeting. It has generally been found advisable, at the conclusion of each meeting, to hand out a definite assignment which requires a certain amount of thought and activity preceding the next meeting. This not only assures continuity, but furnishes additional material available for immediate discussion in the subsequent meeting. An example in discussing information-giving would be to ask for a list of the questions which are asked most frequently, and the answers to them which the service man has been in the habit of giving.

Cautions

Certain outstanding cautions should be given to every supervisor who acts as a group leader:

> As outlined under the opening of the first meeting, the supervisor should never refer to the fact that he is dealing with subordinates.
>
> The leader should not talk at any time any more than is absolutely necessary, either to promote discussion or to crystallize conclusions.
>
> He should not make arbitrary statements and should never say, "You are wrong," or "That's not so."
>
> The conference leader must know his subject so that he will be in a position to anticipate questions that may be raised or statements that may be made. Although he knows the material well, he must avoid posing as an instructor, but must ask such questions as will lead the discussion to logical conclusions.
>
> He should not permit members to become personal in their arguments.
>
> He should not allow the members to "pan" the company or other departments in defending their own positions, but must be in a position to explain company and departmental policies which prescribe the methods which may be criticized.
>
> He should not allow a few members to dominate the major portion of the discussion, nor should he allow other members to sit idly by, taking no part in the meeting.
>
> He should not be afraid to allow a certain element of humor to enter now and then in order to liven up the meeting and to avoid the development of a strained situation.

There are available a considerable number of excellent textbooks dealing with conference-leading techniques, and although the training man should avoid forcing this material onto the supervisors, he should compile, in advance, a bibliography which he can supply them as they realize the necessity for such material. In his contacts with the supervisors, he can gradually encourage them to interest themselves in such text material.

Training on General Company Information

The observation of the representatives of many companies indicates the need for training of public-contact employes to give them a wider acquaintance with the activities and problems of other departments than their own. While in a small company the close contact of the employes doing different kinds of work, and the frequent conversations between them results in an interchange of information, in the large companies this situation does not exist to the same extent. For this reason various plans have been suggested to aid employes in increasing their knowledge of other departments, so that if they do not know all of the details in answer to a customer's question involving another department, they may at least know the proper department to which to refer the customer for the information desired.

Because of the close interrelation between various departments, it is necessary that complementary improvements in methods be effected if the maximum benefit is to result from a training program. In order to secure a sympathetic understanding of the methods and problems of the related departments, it is frequently desirable for representatives of such groups to attend meetings of other departments. In this way, as the result of an interchange of opinions, improved interdepartmental procedures can often be outlined, better information can be given to a customer asking a question involving the activity of another department, duplication of effort can be curtailed, and a closer understanding and a more friendly relation created between related departments.

Many companies provide for the holding of combined meetings of the members of two or more departments where the problems and activities of each department are discussed. If this plan is followed, the schedule of meetings should be so arranged that each person comes in contact with all of the departments in the company, or at least with those departments about which it is necessary for him to have considerable information. This plan is especially suited to the smaller companies, where the individual departments are correspondingly small. In very small companies meetings may be arranged where all employes may attend at the same time.

Another means of promoting interdepartmental understanding is the provision for trips of inspection and study by members of one department to other departments. Here the observation of what is done and how it is done is first-hand.

Another method of disseminating information about other departments is the preparation of printed material about them, which can be handed out and to which reference can readily be made when the occasion demands.

TRAINING BY THE INSTRUCTION METHOD

If the instructional method is to be used in the training program, the work of analyzing the service man's job from the standpoint of its personal service elements might be conducted in very much the same manner as outlined under the first plan. After the training man, however, has satisfied himself that the analysis is complete and that all necessary information is at hand, he will prepare the training material for presentation.

In companies where the lecture method of presentation has been used, it has been found that the material can be presented in a series of six well-planned lectures. In at least one case the lectures have been supplemented by personal conferences between the training man and the contact employe. Other methods which might be used are bulletins, pamphlets or other printed text material. This material might be used as text material, and the instruction could take on the form similar to classroom recitations.

The chief advantage claimed for the instruction method of training is that the material is prepared and the training program is handled by the training man who is an expert and experienced teacher, and that considerable time is saved in presenting the material to the employes. Others maintain, however, that the material cannot be made effective by the lecture method because the lectures must necessarily be general, while to be effective the training material must be specific. "Be polite" is not sufficient, but all that goes into politeness must be developed, if the idea is to be conveyed to the contact employes effectively. This same principle applies to the other factors which have a bearing on the training problem. For this reason it is contended by many that, if the instructional method is used, the material must be developed and presented separately for each specific line of work, and not for the company as a whole. The disadvantage which is pointed out by advocates of the conference method is that this method is primarily one in which the contact employe acts as the recipient of information that has been prepared and compiled by an expert, who usually cannot be as intimately acquainted with many phases of the contact employe's job as is the contact employe himself. Another difficulty pointed out in this method is that the only logical follow-up for such training is more lectures or more instruction.

Regardless of the criticisms of the instructional method of training, however, it must be admitted that it is the only method that can be applied in the case of the new employe or in the case of an employe who is transferred from non-contact to public-contact work. It must also be admitted that in public-contact training, as in other phases of training, the instructional method must be resorted to in that portion of the training that deals with the purely technical phases of the problem.

TRAINING FOR IMPROVED TELEPHONE CONTACT

A general analysis of all telephone-contact jobs will disclose the fact that all of the factors which were found to enter into the making of a satisfactory final impression on the customer, except personal appearance, must be considered in the case of the telephone-contact employe. Further analysis will disclose the fact that some of the items entering into the various factors are common to all telephone-contact jobs. The study will also emphasize the fact that since the telephone-contact employe cannot influence the customer by facial expression, gesture, or an otherwise satisfactory appearance, it will be necessary to lay especial emphasis on voice inflection, selection of words, salutation, and the general manner of speaking. Since many persons have been continuously negligent on enunciation, pronunciation and voice inflections, experience has indicated that training in these matters in this field by actual instructional procedures, including necessary practice, is a very beneficial adjunct to other training of telephone-contact employes. One method that might be used, therefore, is to train intensively all telephone-contact employes by the instructional method in the technique of telephone conversation, and then group the telephone-contact employes departmentally in small discussion groups for the analysis and discussion of the problems peculiar to the telephone-contact employe's job in each departmental unit of the company. The methods prescribed for the service man would apply in the case of the discussion portion of the training program for the telephone-contact employes.

The results of the discussion meetings in the several groups can then be summarized into a Standard-Telephone-Practice Manual for the company as a whole, which will include all of the instructions and cautions which are applicable to all telephone-contact jobs, regardless of department. This, together with other material that will be developed for the individual departments, can be used as training material for the new employes as they come into the picture.

TRAINING FOR IMPROVED STANDARDS OF CORRESPONDENCE

Analysis of the possible contacts with the public through correspondence will develop the fact that, as in the case of the telephone-contact employe, personal appearance does not enter as a factor. It also develops the fact that vocal speech can play no part in creating a good final impression on the recipient of the letter. All of the other factors, however, do apply, and since they can be expressed only through the written word, it is apparent that too much care cannot be exercised in the proper selection of words and phrases, and even in the mechanical way in which they are set down on the page. Similarly, the element of politeness in letters must be especially stressed, as there is no opportunity for facial expression or pleasant tone of voice to overcome a poorly selected phrase. Therefore, the special instruction which is required covering training for improved correspondence will be concentrated on proper vocabulary and on the construction of the letter, so that they will be complete, although brief, clear, accurate and simple in construction.

As in the case of personal contact and telephone contact, conferences with the members of the departments handling the bulk of company correspondence should be conducted by the person responsible for the promotion of this phase of the training program. However, standards for the company as a whole should be set up and promulgated for the guidance of all employes who are required to conduct correspondence in the name of the company.

RELATION OF PUBLIC-CONTACT TRAINING TO OTHER TRAINING PROGRAMS

In many public-contact jobs, such as, for instance, the job of the collector, or the cashier, or receiving teller, the training which has to do with the personal elements of the job practically completes the training necessary for that particular job, except, of course, for a few rules and regulations in which the customer would not be interested. However, in the case of the service man's job which has been analyzed, it is found that the service man must be a good mechanic. The personal service element in the service man's job is an important part of his activities on the customer's premises and is, therefore, a part of his job, so that training in this phase of the work is, in the last analysis, job training that has to do with that particular part of his job. The only advantage to be gained by separating this training from other phases of job training would be in the emphasis that can be placed on the importance of the personal service elements of the job. When, however, the Standards of Personal Service have been established, and when they have been accepted by the existing personnel, there is no reason why the training program for new employes cannot cover the mechanical and personal elements of the job simultaneously. Industry does not separate accident prevention training from the training in methods; that is, the training in methods includes such safety precautions as are necessary to instruct the employes in the correct methods of doing the work. Therefore, in the training program for the new employe, all elements entering into the work of the job should be included in the training program. If this is done, the personal service elements of the service man's job will be given as much emphasis from the standpoint of importance as is given to the mechanical phases of the work.

It, therefore, should be the aim of the training staff to build the public-contact training program in such a way that eventually it can be made a part of the over-all job training program for the departments.

DAY-BY-DAY SUPERVISION AND TRAINING

The supervisor cannot depend entirely upon the meetings for results. Particularly in the case of new people and when new proposals have been made, the supervisor must personally observe how the work is being done on the job. The experienced workman frequently assists in the training of the new workman. He also makes suggestions which the supervisor or the staff man may use in conducting training meetings. The supervisor must ask questions and make notes for discussion in later meetings. In this way the group members will see that the training is a continuous process, and not something confined to the discussion meetings.

TRANSITION

Frequent reference has been made in this report to the use of material obtained by service sampling or otherwise in the follow-up or re-training which is always necessary to keep the adopted standards alive and in use. The results of the survey reported in Publication No. 278-52—Training for Better Public Contact—Its Necessity and Importance—indicated that a number of companies are utilizing various methods of measuring the results of their public-contact training. Management cannot be sure that the standards which have been established are being carried out unless some definite and effective method of measurement is established.

One of the most effective means of carrying on follow-up or re-training is to discuss the results of failures to follow out the standards that have been adopted. Such results in the personal elements of the job cannot be obtained unless effective methods of measurement are established. The next and final report of this series will, therefore, deal with the measurement of results obtained by public-contact-training programs.

TRAINING FOR BETTER PUBLIC CONTACT—IV MEASUREMENT OF RESULTS OBTAINED BY A PUBLIC CONTACT TRAINING PROGRAM

INTRODUCTION

The preceding report of this series (Training for Better Public Contact—Building and Conducting the Training Program, Publication No. 289-83), outlined the various steps involved in the training program from the time it is proposed to the time it is actually inaugurated. Frequent reference has been made to the fact that materials obtained from the various sources which test or check the performance of employes may be used in the training program. Similarly, these tests and checks may be used to determine the improvements resulting from the establishment and continuance of the training program.

Electrical utilities for many years have tested the various materials, such as coal and water, which they use in producing electricity. They have also established laboratories for testing the various types of machinery and equipment before they are placed on the company's system. Electrical appliances sold to customers are similarly tested. No factory manager would think of discontinuing the inspection of the product in each step of his manufacturing process. This inspection is for two purposes: To determine, first, the quality, and, second, the quantity of the machine, and employe output or accomplishment. Knowledge of both of these items is necessary to train the new employe properly in the methods to be followed in producing quality product, and in training him how to come up to normal quantity production. The principle of testing or measurement of the personal service which employes give to customers is entirely consistent with the well-established practice of testing physical equipment, and measuring service and production.

Better Customer Attitude

The product obtained by the company from personal service to the customer is the impression such personal service makes on the customer. Since the training program is carried on to improve the personal service rendered, the results of public-contact training should be, in the last analysis, better customer attitude toward the company. Any measurement of employe knowledge of what should be done that does not include a measurement of the employe's ability to put the knowledge into effective use, can lead to but little indication of the effectiveness of the training program. The most effective method of measuring the mechanic's ability is the inspection of his product as to quality and quantity. No one would think of rating a mechanic for promotion or compensation only on tests of his ability to pass an examination which would determine how much of the training instructions he has assimilated, without also checking him in some way on how well he can apply that knowledge. In the case of the public-contact employe a test of how much he knows about what should be done and on how to do it, will not be indicative of his ability to apply that knowledge unless the actual product—customer attitude or customer impression—is measured.

This report will outline various methods of measuring the results of public-contact training based on answers to the questionnaire described in the first report of this series (Training for Better Public Contact—Its Necessity and Importance—Publication No. 278-52).

Checking Results

Perhaps the first reason for measuring the results of public-contact training is the desire to know what improvement, if any, has resulted from the training work. Regardless of the method of training chosen, it will be successful chiefly in proportion to the interest which is aroused in it on the part of the executives, supervisors, and employes. Further, if this interest is translated into an active effort to improve results with customers on the part of those who are being trained, the results should be tangible. The best way of determining whether the interest in keeping public-contact work at a high point, and whether the actual quality of the work has been maintained, is to carry on some kind of measurement of the customer's impression created by the personal service rendered.

THE METHODS OF MEASURING RESULTS

1. In the first report of this series the methods of measurement used by the companies answering "yes" to the question, "Do you use any method of measuring the results of your public-contact work?" were stated to include:

    Investigation and record of customer's complaints;

    Review checks on information in training material;

    Continuous service sampling of performance on job;

    Follow-up with customers to see whether such items as work orders have been satisfactorily carried out;

    Direct inquiry to community leaders as to the standing of the company.

    Details of these methods were submitted by the companies which later furnished supplementary material on the subject of measurement. While an analysis of the various methods in use indicates a great variety of devices, certain trends may be noted. The methods in use, although varying in detail, will be classified according to the elements they have in common.

Publication No. 289-108, Serial Report, Industrial Relations Committee.

2. Classification of Methods of Measurement in Use

a. Methods of measurement may be classified as direct or indirect.

The direct methods include all methods in which an attempt is made to obtain directly from the customers or from others familiar with their attitude, an indication of what their reaction has been to the personal service which has been rendered. The indirect methods include those procedures in which no attempt is made to obtain a direct statement from the customer. Under the indirect method, the employe's knowledge of prescribed methods and his ability to apply this knowledge is judged by carefully noting his performance while he is making contacts with the public, or with someone posing as a customer.

b. Methods of measurement in use may be classified as formal or informal.

Formal methods are those in which a definite time schedule is adhered to in conducting the measurement, and in which definite procedures for carrying on the measurement are used. An informal method is one in which the person seeking information uses an analysis of the general attitude as expressed by the customer, rather than hard and fast formal questions.

c. The methods of measurement may also be classified as specific or general.

Where the specific method of measurement is used, information is sought regarding a definite situation in which a particular class of work is being measured. In the general method, the purpose is to secure an over-all impression of the customer's attitude toward the company as a whole.

DIRECT AND INDIRECT METHODS OF MEASUREMENT

In the previous report the methods of training the service man were discussed. In this report the measurement of the results of that training will be discussed where applicable. It is assumed that similar means would be used in surveying the results of training in other lines of work. In many cases the survey would be company-wide, covering all public-contact positions.

1. Direct Methods

a. Professional interviewers

Interviewers, who may be either employes of the company or an outside concern, retained by the company, are sent to interview the customers in their homes or places of business to ascertain their attitude toward the company, based on the treatment they have received from company employes, and upon the physical service rendered. The advantage claimed for this method is that it permits the use of people who are specially trained in methods of securing information by asking questions without antagonizing those questioned. Another advantage is that the interviewers can do much to conciliate customers who have received a bad impression of the company for any reason by a frank discussion of the situation. The disadvantages are that many people are somewhat reticent to answer any questions, and if the interview occurs at a time very distant from their last contact with the company, their impressions may be extremely hazy.

b. Reply cards sent to customers

This device, as the name implies, is a follow-up of the service rendered to determine the customer's reaction to the service, while the situation is still fresh in the customer's mind. The advantage pointed out for this method is that it secures an analysis of the customer's reactions to a concrete situation while it is still fresh in her mind and while any courtesy or discourtesy shown by the employe is easy to remember. Another advantage is that this method lends itself readily to application in small communities. It is pointed out, however, that care must be taken in preparing the card so as to make the appeal as personal as possible.

c. Analysis of complaints and letters of commendation

This involves a study of these communications in an effort to learn directly from their own correspondence or oral statements the reactions of the customers to the company.

It is asserted that the advantage of this method is that it is based almost entirely on unsolicited comments by the customers about the service. An objection to placing too much importance on complaints and letters of commendation is that they represent such a small fraction of the customers and the statements are usually exaggerated in criticism or in praise, while the large middle group of customers who are either neutral or mildly friendly, seldom communicate with the company.

d. Inquiries directed to community leaders

In this method the purpose is to obtain the over-all reaction of men in prominent positions in the community. Where this method is used, it is normally a personal conversation between an executive of the utility concerned and various community leaders with whom he has either social or business relations, or both.

The advantage of this method is said to be that the opinions of these community leaders are based on wide observation of the reaction of the community to the utility's service and its treatment of its customers. The disadvantage is said to be that the statements are the result of a general conversation rather than a specific interview, and that the opinions expressed by these leaders are usually personal rather than representing any considerable number of people. Usually the leaders are themselves connected with some large commercial or industrial organizations, and so look at the problem from that position rather than from that of the average domestic customer. It must be admitted, however, that an opinion gained by this method should not be disregarded because it can serve as an over-all check on other methods which are used. Another disadvantage is that the same subjects cannot be brought up for conversation at regular intervals with the same community leaders.

2. Indirect Methods

In the indirect method a third party either acts as a customer and, based on a study of usual customer reactions, rates the employe's performance, or, acts as a monitor to determine to what extent the employe is making an effort to do those things which will result in a favorable customer reaction.

a. Service sampling of employes

In this method, certain people selected because of their ability to analyze situations and to take an impartial view, assume the rôle of customers and carry on what appears to the employe to be a normal business transaction. Having studied the things which seem most important to the average customer, this sampler, after the interview, rates the employe according to the extent to which he has done the things normally expected to produce a favorable impression. As indicated in the preceding serial report, Appearance, Politeness, Speech, Information-giving, and Interest in the Customer constitute these points on which the Service Sampler will rate the employe. The advantage claimed for this method is that it permits the taking of samples of personal service on any phase of the company's business where the employes have contact with the public which, by most other methods, might otherwise be very infrequently sampled. Further, it permits a numerical measurement of employe performance based on definite standards. This measurement, based on definite standards, would be difficult to make on information obtained from the customers. By the use of this or any indirect method the customer is not required to participate in the company's effort to improve its personal service. The possibility of irritating an otherwise friendly customer is thus eliminated. A disadvantage claimed is that unless the employes understand that this is a strictly sampling proposition and not a disciplinary device to detect offenders, they are likely to look upon it with suspicion.

b. Monitoring and spot checking

As in the case of the Service Sampler, the Monitor or Spot Checker, knowing what has been agreed upon as carrying the most weight with the customer in producing a satisfactory impression, can rate the employe during the progress of the employe's contact with the customer. An advantage claimed for use of the monitor or spot checker is the ease with which his work can be accomplished. This is especially true in the case of telephone and correspondence contacts where the tying-in of an extra telephone permits ready monitoring of conversations, and where the reading of correspondence after it has been written may be readily accomplished. The same disadvantage, as sometimes claimed against the use of service sampling, applies here unless the purpose of the plan, as understood by the employes, is to improve service rather than to collect information to be used for disciplinary purposes. Another disadvantage is that there are many contact jobs to which this method cannot be applied.

FORMAL AND INFORMAL METHODS OF MEASUREMENT

Various plans used under the direct and indirect methods of measurement may be adapted either for formal or informal use, or to measure specific or general situations. Ordinarily all of the plans listed would probably be carried on formally except inquiries directed to community leaders and, except on certain occasions, reply cards sent to customers, and analyses of complaints or letters of commendation.

In the formal method of measurement, a definite routine is established whereby a time schedule for the conduct of the survey is set up, the physical setup is carefully outlined, and formal questions are asked to which definite answers are expected.

Advantages and Disadvantages

The advantage claimed for this method is that the routinizing of the work permits it to be carried on on a regular basis, and provides for definite comparisons which will indicate the progress made.

A disadvantage of the formal method, when applied to the direct method of measurement, is said to be that many customers find it difficult, and many are unwilling, to analyze definitely their own reactions to their treatment by the company, who might, if approached informally, give some of the desired information.

Under the informal method, as the name implies, private conversations and letters between company representatives and customers are used with the idea of gaining more offhand comment than is obtained when a formal routine is adhered to.

A disadvantage claimed for this method is that it is difficult to use information gained informally as a definite measurement, as it represents only such thoughts as immediately arise in the customer's mind in the course of the conversation. Similarly, the measurement is limited, and the results of measurement cannot be used directly in providing for training to improve the work.

SPECIFIC AND GENERAL METHODS OF MEASUREMENT

The plans of measurement already classified as to direct or indirect, and formal or informal, may also be classified as to whether they are specific or general. As already indicated, the specific method is the one used where information is sought regarding the impression left in a definite situation in which a particular class of work is being measured, while in the general method the purpose is to secure the final impression of the customer's attitude toward the company.

Analyzing the methods on this basis, it would be found that ordinarily the analysis of complaints, the sending of reply cards to customers, the service sampling of employes and monitoring and spot-checking of employes, and interview with customers are specific methods. On the other hand, inquiries directed to community leaders are almost certain to be general, while some of the other devices may be used to measure the general attitude toward the company.

Advantages and Disadvantages

An advantage claimed for specific methods as applied to a company where training for improvement in public contact is being conducted, is that it allows specific measurement on the work of holders of positions who have received specific training in the public-contact responsibilities of those positions. A disadvantage of this plan is said to be that it is difficult to measure the attitude of the community toward the company by the consideration of a limited number of isolated public contacts.

The measurement of the performance of public-contact employes by the general methods can be best applied to those phases of the work in which the training has been company-wide, for example, general telephone training. Not only is this claimed to be an advantage, but also the measurement of the attitude of the customers toward the company as a whole, indicates whether the majority of the customers are friendly, unfriendly or neutral in their final impression of the employe's personal service. A disadvantage of the general method is said to be that it is very difficult to determine the extent of the success of the training program by using general methods of measurement.

APPLICATION OF METHODS OF MEASUREMENT

In the preceding serial report the method of analyzing the work of the service man, and of setting up and operating a public-contact-training program with and for him, was discussed. The various methods of measurement must be considered separately as they apply to measuring the results of training of the service man. In order to have a fair basis of comparison so as to determine what improvement has resulted from the training program, the quality of the work of the group being trained should be measured before and at intervals after the training program is inaugurated. The same measuring devices should be used in both cases. The choice of the method of measurement will probably depend chiefly on the local situation, as methods which are practical in urban communities would be impractical in scattered rural communities and vice versa.

Interviews with customers regarding the work of service men, analysis of complaints, letters of commendation with reference to service men, sending of reply cards to customers recently visited by service men, or a combination of two or all of these direct methods of measurement might be used. Similarly, situations might be arranged so that customers or service samplers can call upon the company for service and make service sampling reports based on the resulting contact. To be most effective, the measurement of the customer's impression of any of these situations should follow as soon as possible after the visit of the service man, and the whole program of measurement should be begun shortly before the starting of the training program, and be continued from that time on.

As indicated above, to be most effective, the formal plan with a definite schedule upon which the measurement would be based and the routine for handling the method agreed upon, should be arranged. In the case of the service man, a workable arrangement would be to provide for a certain minimum number of test cases or samples, reply cards or interviews, or a combination of these various tests to be made on a definite schedule.

Since it has been stated that the job of the service man is the one under consideration, obviously specific measurement of the results of his public-contact training should be considered. Under this plan, the questions to be answered and the points to be considered in setting the standard upon which the measurement is to be determined, will be based directly upon the standard of performance to which the service men and supervisors have agreed. This also furnishes an excellent check to determine whether the service men are practicing the things which they agree in their training meetings should be done.

RELATION OF MEASUREMENT TO THE TRAINING PROGRAM

As just indicated, measurement is a very important part of the training program. During the early stages of the training program it is necessary, from time to time, to give examinations, sometimes called review checks, on employes' knowledge of the standards which they have agreed are to be maintained in the future. These checks are tests of knowledge of what should be done, and not of the performance itself.

Various other methods of measurement which have been described in this report are measurements of actual performance on the basis of the standards which have been agreed to in the training program. When a comparison of the review checks on knowledge with the checks on performance indicates that the performance does not come up to the standards which the men themselves have set, any one of a number of reasons may be advanced—that possibly the employes have outlined an ideal standard rather than a practical one; possibly proper supervision is not being maintained to secure adherence to the standards; and possibly the employes do not thoroughly understand the details of the standards to which they themselves agreed.

Information Obtained Serves Other Purposes

The information obtained by measurement also serves other purposes. It helps to indicate how standards should be changed to conform with changing situations. It also forms a basis of comparison between similar situations over whatever period comparisons are considered desirable.

Still another excellent use for the results of measurement is to furnish first-hand-case illustrations based on the man's own performance to be used as training material. Training must be a continuous process and is an important part of supervision. Measurement, however, furnishes an indication of when training should be given additional attention and also what points should be emphasized in the continuing training program.

The final results of measurement form the basis of reports to the management of the departments concerned as to exactly what progress is being made in the realization of the desire to create the best possible impression on the part of the customer.

Recommendations of the Committee

The committee recommends that each executive, having recognized public-contact training as an important factor in maintaining good public relations, study his own local conditions in order that he may determine the best method or methods for him to adopt for the conduct of the training program, including the measurement of the results of the training. It is further recommended that these results be measured periodically and compared with previous results; that training be continued and that reports showing the results of training be presented to the management.

HEALTH PROMOTION IN THE PUBLIC UTILITY INDUSTRY —ITS NECESSITY AND IMPORTANCE

INTRODUCTION

In the Reports of the Accident Prevention Committee for the years 1920-21-22 and 23,* there will be found references to the problem of Health in the Public Utility Industry. In the Reports of the Industrial Relations Committee for the years 1926 and 1927* will be found further references. These references for the most part deal with the problem of sickness, absenteeism, and physical examination. Anyone interested should give this whole subject careful consideration.

As has conclusively been shown, sickness is responsible for approximately eight days' absence per employee per year. This loss is, for the most part, caused by what are called minor illnesses, such as the "common cold." The importance of these illnesses is clearly demonstrated by the investigation recently inaugurated by the Johns Hopkins University, into the cause and treatment of the common cold.

Aside, however, from absenteeism, is the recognized value to the employer of the long-lived employee. In a public utility this is even more apparent because the plant of the public utility is not in one factory, but is spread over either a city or a considerable stretch of country, and whether the employee be lineman, meter reader, bookkeeper, salesman or manager during the period of his employment, he has collected a great mass of information relative to the particular public utility with which he is connected, which, however carefully recorded, will be lost if he leaves the organization. Aside from humanitarian reasons, it is, therefore, of particular interest to the public utility to help its employees lengthen their lives.

Important as is the economic reason for health supervision, for the most part a natural interest in the well-being of the man or woman, is the real reason for the interest of companies in health matters. So much of our lives is spent at business that we are naturally pained on learning of the untimely end of an associate, or the severe illness of one working under our supervision. It is, therefore, logical that plans should be made to assist in preventing illness, and that companies should use the motto, "Work here and live longer."

The strains of modern business have greatly increased. Whether because of keener competition or as the natural result of our machine age, there is no doubt that this strain on the man is being felt. Even aside from business, the idea of competition and speed is also being carried into the various pursuits in which the average man seeks his pleasure. In other words, with the general speeding up of life, whether in business or whether in play, the physical make-up of the average man is bearing a strain to which, in a number of cases, it is unequal.

This strain, quite naturally, falls more heavily upon the man bearing the major responsibility. This man may be called boss, foreman, vice-president or executive, but irrespective of the name, the strain upon him is usually very much greater than that upon other employees. As is quite usual, the importance of his health is not receiving the attention it should receive, but certain organizations are at least trying to rectify this defect.

Although emphasis is being placed on the care of the executive's health, it is not intended that the health of the rank and file be neglected. It is felt, however, that while many executives arrange for the health supervision of employees, they seriously neglect their own health. The average employee needs assistance in health matters much more, however, than the executive. Often the financial means are not available, and only by cooperative methods can it be possible for the employee to get the advice or the attention required. In this situation, the company can be of great assistance.

DEVELOPING A MEDICAL DEPARTMENT

The matter of organized effort to care for the health of the employees of the organization, has been receiving attention for a considerable number of years in some organizations. It is rather noticeable that, although very few N. E. L. A. member companies have done anything in health matters in an organized way, those few companies which started an organized effort twenty or twenty-five years ago, have maintained this effort and have extended it, showing quite clearly that the policy decided upon has proved well worth-while.

A word of warning should be given as to the necessity of developing a medical department slowly and not attempting to embark on an extensive plan at the start. Practically all successful medical departments have been developed over a period of years, meeting and solving problems as they come up and developing the type of department necessary for the particular company in question.

Most of the companies which have become interested in the health of their employees have instituted some form of physical examination at the time of employment. These physical examinations vary from a rather cursory examination to a most complete medical and physical examination. Physical examinations to be of real value to the employee or the company should be thorough, complete and dignified. The superficial examination gives the company little information, and does much to discredit health activities and the company in the eyes of the employee. Better no examination than a superficial one. In certain types of employment, a check is made for specific physical defects that would render either employee or the public subject to a considerable hazard. These special checks have particular reference to hernia, color blindness, deafness, heart lesion, etc., among specific types of employees. Certain companies have put into effect a periodic examination, the period ranging from six months to a year, at times being carried out by the medical staff of the company and at other times by an outside agency. If carried out by an outside agency, the medical staff of the company should follow up. For the most part, these examinations are to provide means whereby advice can be given to the employees on the correction or prevention of various types of development that might result in either chronic illness or death.

---

*These Reports are included in the N.E.L.A. Proceedings for the years mentioned.

Publication No. 289-56, Serial Report, Industrial Relations Committee.

Entrance and Periodic Examinations

The advent of Sick Benefit Plans in the industry has no doubt had a definite influence in developing both the examination on entrance and the periodic examination. Those companies which have had experience with both the entrance examination and the periodic examination, feel that these activities have been beneficial in lowering the absenteeism due to illness and in otherwise improving the efficiency of the staff.

In the larger organizations, particularly where there is a considerable group of employees, Medical Departments have been set up, ranging from a complete department, with full-time surgeons and the necessary nursing and clerical assistance, with examination rooms, treatment rooms, X-ray apparatus and laboratory facilities, to a part-time physician, usually in a consulting capacity. It is rather marked that those companies which have carried out the idea of a Medical Department for some years have enlarged that department, and from time to time have increased its functions, showing that those with experience along this line feel that the department is of considerable value.

A considerable amount of health education among employees is done in a number of companies. Various means are used, such as lectures, pamphlets, motion pictures, etc. Some of the larger companies have made definite provision for athletics, and in a few cases, vacation clubs, etc., have been developed. There is no doubt that this organized method of health education has a very definite, beneficial effect on lowering the absenteeism and in other ways improving the efficiency of the staff.

In setting up these various Medical Departments, considerable care has apparently been exercised to gain and keep the full cooperation of the various family physicians of the employees. This is most important, in view of the difficulty that public health departments apparently have had in connection with public clinics, and the industry would do well to encourage this close cooperation with the family physician.

The prime object of a physical examination is to detect indications of disease in the incipient stages, when remedial measures can be put into effect and prevent the onset of the disease. In a group of persons, it will usually be found that those under 40 years will show a healthy constitution with no indication of disease. However, there will be a very small minority which show indications, which in certain cases can be rectified. In the group of over 40 years of age there will develop more chronic diseases, and more definite remedial measures will have to be put into effect. In general the group under examination needs but little advice along the lines of reasonable living to keep it in good health. There will be found, however, men and women who seriously object to a physical examination, feeling that it is an encroachment upon their personal liberties. This will not be found so much in an examination for employment but will develop more in the periodic examination. Careful attention to this condition should be given by the examining doctor, and every care should be exercised to break down this antagonism.

Another serious defect of physical examination is that, in many people, a physical examination creates a fear for their health. Most people worry too much about their health and do too little to keep in good health, and it has been found that a certain number of this type will be very much worried by the results of a physical examination. Careful attention by the examining doctor at the time of the examination will do a great deal to offset any difficulty of this type. In fact, the doctor should make it his duty to explain the reasons for the examination and also how the employee can obtain the greatest benefit from it.

Physical examinations are, for the most part, made either by the company doctor or by an agency employed directly by the company for this purpose. A great deal is to be said for this policy. These doctors are, or should be, more skilled in physical examination than the average practitioner. The examination report will be more completely filled out, and the examinations will be more uniform. There is certainly something to be said, however, for the policy of having a physical examination executed by the family physician. The employee looks to the family physician for advice in health matters; there are no social antagonisms to be broken down between employee and the family physician, and, furthermore, the family physician should know the condition of the employee better than anyone else. Although it has not been done extensively, the experiment of having the family physician make periodic examinations of employees and report to the employer is well worth considering. The contact set up with the family physician would be very valuable and the advice to the employee in health matters by the family physician might be better received and more likely to be carried out than advice given by a stranger.

Where examinations are to be made by the family physician, he must be acquainted with the objects of the examination and pertinent facts in connection with the employment. This information can best be given by the medical staff of the company.

In connection with the Health Department set up in various companies, the decision has always to be made as to how far to go. Certain companies, as pointed out previously, have instituted a very complete medical clinic. Such clinics are more common in the manufacturing industries in which the employees are concentrated. In a public utility, with employees scattered over a considerable stretch of country, it is much more difficult to set up a complete medical clinic. Also, the wisdom of setting up such a clinic is certainly open to question, and each company will have to decide for itself as to how much medical service it intends to give the employees and how much responsibility for the medical care it intends to assume. This is such a debatable point that the Industrial Relations Committee feels that, at present, it should be left an open question.

EDUCATING FOR HEALTH

One form of activity, however, can be carried out by the company with the greatest propriety. There is available a mass of reliable and helpful literature giving advice in health matters. This literature can be carefully selected and presented to the employees in the company's usual way of presenting information. This information may be obtained from insurance companies, public health organizations, medical organizations and certain bodies which have developed this as a specialty. In the collection and selection of this information the assistance of physicians and those thoroughly familiar with the problem is of the utmost importance. A great deal of so-called health information is published and broadcast, which is anything but healthful and is, for the most part, the product of faddists. One of the greatest difficulties in educating in health matters is to get the idea across, without leading the employee to think that he is a chronic invalid. Most people are normally healthy; in fact, very much more healthy than they realize.

In setting out to educate employees in health matters it is, of course, imperative that the company set an example. It is foolish to send out information about the need for ventilating the home, if the company's premises are not properly ventilated. As a forerunner to a campaign of health education a careful survey of the company premises by someone who is competent to give advice on sanitation, health, and ventilation, will be found to be of considerable assistance.

Contacts With Health Agencies

It will be of value to the company to become thoroughly familiar with the health agencies carrying out work in its territory. The Department of Public Health, the local medical societies, the Red Cross and other social service organizations, as well as certain departments of hospitals, will be found not only able to help but glad to do so. By setting up such contacts, a great deal of overlapping is eliminated and advice of valuable character in dealing with the company's own problems will be obtained.

The contacts with the family physicians, as above pointed out, will be valuable in carrying out any type of health education and instruction. In setting up these contacts with the family physician, the company will not only gain by the instruction that can be given by the family physician, but will also gain by instructing or educating the family physician in the requirements of employment in the company and in the company policy in connection with its employees. Such contacts may easily assist where a close relation is made with the family physician, whereas, if the family physician is not taken into the confidence of the company and his assistance solicited, detrimental effects may develop.

In Conclusion

The health of all of the staff of any industry is extremely important to the industry's success. Good health will cut down absenteeism; will make for long-lived employees and will assist in creating efficiency. To obtain the good health of the staff, the advice of those instructed in health matters, such as doctors, nurses, etc., is imperative. How far the company should go in treating illness is a debatable point. Certainly, assistance should be available in emergency and in certain other cases. There can be no doubt, however, that instruction in health matters by the company through the best means available is advised.

A certain school of thought in public health matters is developing which would advise that the employee be held responsible for his health as one of the requisites of holding his job, and that the company assist in educating him as to how to maintain good health.

APPENDIX I

HOW THE MEDICAL DEPARTMENT CAN BE A FACTOR IN THE REDUCTION OF ABSENTEEISM FROM WORK

When the average person anticipates making a purchase of any commodity he first has in mind what he desires to buy, what it is for, its quality and if it is worth the price. It is true that many times a purchase of a commodity is pure guesswork, but the average customer, after careful selection of his article, pays a fair price and gets value received. It is the careless, impulsive buyer, who selects without discrimination, who generally becomes dissatisfied with his purchase.

The same care necessary in purchasing materials should be exercised in employing men and women for work in a given industry. It is just as essential that the employer have in mind definite facts that will guide him in his selection of a person able to do efficiently the work that the vacant position calls for. If a candidate for a position is selected on external appearance only, the interior is unknown. He may meet the requirements and be capable of performing the work, but be unable to stand up physically on the job. This can be determined only by a careful physical examination of the prospective employee before he is taken into service. The examination should be made before employing, and not after the man is trained, when the discovery of hidden defects may require his discharge.

THE PHYSICAL EXAMINATION

To be of any value, the examination must be sufficiently definite and thorough to detect any defect or insidious disease. The few-minute medical inspection is valueless. The examination should be made under a standard set of physical requirements for each position in the industry and careful analysis made of each job's requirements, hazards and environments. After this examination, the employer knows to a greater degree the exact physical qualities of the new employee. The selection has not been made blindly, and he has been fitted into the position for which he is best suited, and which he can discharge efficiently and with safety to himself and those about him.

This is the Medical Department's first opportunity to reduce absence from work on account of either illness or injury. A fairly healthy employee at the start is a known quantity that will not be so apt to be absent from work due to sickness. This examination detects those conditions that make for illness and are potential factors in accident making. Defective eyesight, hearing or color sense, all predispose to illness and accident, and if these are undetected in a new employee, is it not to be expected that sooner or later these will cause him, or others about him, to be absent from work on account of illness or some injury in which either he is the victim or those about him suffer from his defect?

An employee who has a rupture, defective heart, defective limb, due to crippling, or such defects as flat feet or varicose veins, is a great offender in absenteeism. Defective teeth and tonsils, by causing complications productive of more serious diseases, play their share. It is better that these conditions be detected and remedied before employment, as otherwise they are often put off after employment and go on undetected until their owner becomes a chronic offender. It is the undetected, trivial physical condition which, if given time in which to progress, will at a later date after employment bring the employee's name on the daily list of those absent on account of illness.

Undetected physical deformities may be productive of injury. In many cases, the defect is such that when a certain work is performed, the man fails and an accident is at hand. This is best evidenced by the workman with a hernia who, while lifting heavy objects, drops his end on account of sudden pain, and his feet or his fellow-worker's feet, suffer. Careful physical examination reduces absenteeism from work in proportion to the thoroughness with which the examination is made.

KEEPING EMPLOYEES IN HEALTH

After a healthy man of known physical make-up has been employed, it is essential that he be maintained in that condition, as far as possible, either by compulsory examination, by his own initiative, or, better still, by the company, as the individual is prone to neglect trivial symptoms and put off examination and treatment. This physical examination detects those conditions that may arise after employment.

Many industries examine all new employees carefully, but end their health work after the man is employed. This must be considered a mistake, for after the employee has been trained and is functioning as a part of the organization, any illness or injury will bring greater loss economically to both worker and employer. It costs money to educate a new employee, and then, too, absence from his work on account of either injury or illness will, in many cases, disrupt the orderly routine of work. Machinery and tools are maintained in a safe and efficient condition. It is even more important to maintain in a healthy state the man who uses the machinery and tools. These thorough, periodical, medical examinations of employees have proved a definite factor in the reduction of absence. If the employee is in good health, he is not prone to respiratory infections, which are the greatest cause of absence from the job. If he is in good health at the time of injury he will be returned to his bench in a shorter time and with fewer disabling complications. For example, the man with a mouth filled with diseased tonsils and teeth is off frequently with rheumatism, lumbago, indigestion, etc., from local infection, and when he is so unfortunate as to suffer some slight injury, complications develop and his disability extends over a long period of time. This is so often seen in the back injury developing from a trivial accident, and, on account of preexisting disease elements, the condition is aggravated, the deformity made more serious and convalescence delayed. Proper periodical and thorough physical examinations will reduce the absenteeism caused by illness and injury.

These two procedures are known as industrial prophylaxis of disease and come under the heading of prevention of absenteeism on account of illness and injury in industry.

There is another group of conditions in industry that makes for a reduction of absence on account of illness and injury, by the establishment of a well-organized medical department. Such a staff or department can render great service and save a vast amount of money by providing systematic methods of handling injuries and illnesses that are prevalent in its particular locality or industry. Where a large group of like medical and surgical conditions are taken care of by an organized group of doctors, greater experience and education in the most efficient manner of treatment is to be had. Without the services of such an experienced medical staff, injured employees may be kept away from the job by reason of prolonged and ineffective treatment by doctors who may not be familiar with such cases because of lack of experience with these traumatic cases. Experience has shown that injured men will, in many cases, return to work earlier when treated in the industrial medical department, where the necessary experience in this field is available, than when they are treated elsewhere. Many times they are fitted in the organization in a capacity where they can have an income and at the same time perform work that their injuries will permit without harmful effect. A man whose mind is occupied with engaging work will recover more quickly than the chap who is idle and allowed to be alone with his thoughts. A little patience on the part of the industrial medical man and cooperation from the department heads will fit this worker in and will reduce the absenteeism from the job on account of illness.

Value of Immediate Medical Aid

How much verbiage has been expended by both the medical man and the layman in industry toward remedying the absenteeism from work on account of illness, but how little real action has been inaugurated? By trying out a definite medical policy in an orderly and systematic manner, results will be produced. In illness, especially in common colds, a great reduction can be made if medical supervision is had at once when the first sneeze is heard or the first drop appears on the nose. A day at home away from the job will prevent contaminating others in close proximity to the afflicted one, and the day's rest under therapy will return him to his bench sooner than if he is left to follow his own dictates and drag his cold out three or more days, with poor work output and inferior grade of work, only later to stay at home with a more defined respiratory case. What is needed in industry is courage to follow out experimentally some of the real established health factors for a definite time and compare cases of neglect, where no treatment is given, and it will soon be seen that there is a definite value returned in proportion to the medical effort put forth. Sanity is essential in this medical work, and one must not by this policy disrupt the orderly functioning of a given industry. Where the medical authority bewails absenteeism from work and his helplessness to check it without disrupting the practical processes of his industry, he is found lacking, and has not started at the bottom of the absenteeism-defect ladder, but is at the top trying to remedy conditions which can only be reached by treatment upon each individual step of the ladder from the ground up. Many times one hears medical department chiefs say that, when an employee presents himself at their office complaining of feeling ill, their duty consists of signing a card for a department head that the employee is sick and should be excused from work. What a sad spectacle it is of a doctor doing this simple, clerical procedure instead of using those professional qualities he possesses, making a careful examination of the patient and giving a written statement of the treatment that he is to follow out while at home; for the greater proportion will go home, try home remedies and get advice from other sources instead of seeking their medical advisor, until the disease has a full hold on them and they are scared, and only then will they seek competent treatment. But if the medical chief interests himself in the individual enough to examine and supervise treatment and then check up the case, he will soon show his value to the executives of his company by a lowered absenteeism rate.

One of the causes of frequent absence from work on account of illness is the sick and health benefits that are in some cases so large that it pays an employee to be sick, as he will derive more money away from the job than at work. Benefits are so often derived from one or more companies that the employee stays at home on trivial injuries and illnesses and many times for no bona-fide cause, when he should be at work. Many ailments are subjective and it is difficult for a doctor to determine by a single examination of the employee whether he is justified in absenting himself from regular duty. This makes it necessary for the company medical department to follow closely each case of absence, so as to insure proper care of real cases of disability, and, equally important, so as to detect those cases in which there is a reasonable doubt as to whether the employee is really disabled. Such a procedure will result in a great reduction in absenteeism and many dollars will be saved to the companies and to the employees' mutual benefit associations. Not all employees are given to this practice, but in any organization employing large numbers of men there are enough malingerers of this type to bring up the absenteeism rate. In so many of the benefit companies the doctor is so submerged under the red tape of the so-called welfare department that his value is lost and his efforts become clerical.

The medical department has a very definite work of sanitation in every industry. A healthful working environment is conducive to a healthful personnel and assures a minimum of absenteeism. Proper illumination of a plant forestalls nervous and mental trouble, as eyestrain is conducive to these defects. Ventilation and heating are essential necessities in every plant if the absenteeism rate is to be kept at the lowest ebb, as underheated or overheated rooms are the direct cause of many disabling diseases. Lack of fresh air, gases, smoke and fumes are the handmaidens of disease germs, and absenteeism mounts with the neglect of these essential features of good health. The medical department, by supervision of the sanitation of any industry is able to lend important aid in health conservation. The analyzing of the greases, compounds, solutions, paints, chemicals, etc., used is a necessary duty of the medical department if it is to prevent industrial diseases. Distribution of published articles, and talks on health subjects, to the employees of an industry, at not too frequent intervals and in common sense language, are important factors in the control of absenteeism.

FIRST AID INSTRUCTION

Instruction of the lay personnel in first aid work in the absence of medical attention in time of illness or accident, has not only conserved human life by immediate assistance, but has been the stimulus of directing the attention of the employee to his own personal self and of inciting him to look after his own health and well-being. First aid has reduced the absenteeism from work, as timely attention to trivial injuries has prevented prolonged disability. Proper first aid reduces complications such as infections, following simple injuries. To be of service, this must be taught correctly and closely followed up afterward. A visiting nurse service has its advantages in helping to reduce absenteeism because the nurse calls on the ill or injured employee within a few hours after his absence is reported and is able very often to bring aid. Her ministrations in time of illness not alone save the employee expense, but also hastens his recovery. The money spent in this nursing work is returnable in a large measure in the morale of the employee body.

PREVENTION

When department or supervisory heads become aware of an employee slowing up, either in his production rate or the quality of his product, they should at once interest themselves in the cause of the letdown. Should the employee attract the attention of his fellow workers by peculiar or unusual actions, these should be looked into, and for both conditions the medical department brought into the picture. After careful examination, many times physical defects or mental crises are apparent, and attention given them at this time will often prevent a prolonged absenteeism later.

More attention should be given to research by the medical department personnel into the mental cause of accidents and its resultant absence from the job. This is a very important factor in industry today. Many employees have accidents for which there is no apparent excuse, and those in industry are at a loss to understand the cause. These occurrences always carry with them a greater period of absenteeism from work than ordinary accidents, as many times there is a mental defect to overcome besides the physical defect. Greater interest on the part of plant executives in the study of the individual instead of mass study, and the calling in of competently endowed medical personnel to aid in the work, will make for a decided lowering of the absenteeism rate.

While on this mental side of absenteeism from work, it is necessary to say a few words relative to the women in industry who so often are the greater contributors to absenteeism. Insufficient periods of relaxation are often the causes of fatigue of the women employees. On account of the average physical makeup of the woman and the fact that many times she is called upon to perform work which is beyond her physical and mental capacity, she functions for a time on her reserve nerve and vitality, but one day this weakens and she becomes a prey to the many disabling conditions to which women are susceptible. The medical department, with its efforts rightly directed in this channel, can reduce absenteeism. Women in industry are a specific problem, but progress is being made medically toward improving this condition.

In Conclusion

In conclusion the point of greatest importance in the industry today is to have each company establish a set medical policy for its employees, and then establish a medical department with a personnel whose interest is in the company and whose ambition is to produce such a state of health in that company that it will command the attention and respect of other companies. The efforts of the medical department, rightfully directed and competently manned, will be a direct agency for the reduction of absence due to illness or injury. There should be more research and less talk concerning this problem. It costs money for anything of value, be it service or product, and if only the interest on the economic loss, due to absenteeism from work, were applied to real active prevention, great headway would be made. Industrial medicine is in its infancy today, but it is here to stay, and as time goes on the medical department will be considered as essential to the successful operation of the company as is any other department of the organization.

In order to start the investigation, it is imperative that the industry keep adequate records of all cases of absenteeism, cause, occupation, length of disability, curative agent, time of year absent, and this study alone will reveal astounding facts that are easy of correction. It will be found that the greatest factor in absenteeism is not the serious illnesses of humanity, but the so-called trivial ailments which are easily corrected and prevented by a little real application to the problem.

Too much indifference is shown to the so-called comforts of workers, such as the arrangement of the work in an environment which is conducive to health for the various calls of nature. Facilities are often lacking and, if present, are inaccessible or inadequate. Often it is said to be impractical to permit sufficient time away from the job to adequately care for the various bodily functions. Constipation, the curse of American manhood and womanhood, is undoubtedly due to the demand of speed in industry and life today. We are too busy to attend to this call of nature, with the result that the organs of elimination will act only under the lash of artificial means, and their poisons remain in the systems to poison other organs and disrupt their harmonious function, and predispose the individual to illness which otherwise would not occur.

Constipation alone produces more absence from work than the much abused cold, for it is generally the constipation evil that so lowers the resistance of the worker that he becomes susceptible to colds. To properly function, the human machine must be kept clean both within as well as without. The correct amount of fuel in the form of food and liquid is necessary for the nourishment of the machine. The proper elimination of the waste products of the machine is essential to its efficient performance. Rest periods, in which the machine may recuperate its energies and lay up reserve power for emergencies, are important, and protection from overheating and underheating the machine will bring about a harmonious operation of that mechanism which

Providence gave each man as his natural heritage for his battle for existence in the world. Attention directed to the little things that produce conditions conducive to illness, with its enforced idleness, will bring a clearer vision to those who are concerned in this problem of absenteeism from work on account of illness or injury than if they direct their attention to the larger things, which will generally be taken care of and not slighted, as are the intangible conditions.

The most effective argument for the establishment of medical department's activity directed toward the reduction of absenteeism in industry is a comparison between the rate in an industry which has no medical policy and the rate in one which has a definite medical policy and a competently equipped medical department to carry out this work. The comparison will favor the latter, and industry is quick to see the value of such policy. The health of employees today is far better than that of a few years ago, but there is vast room for improvement.

APPENDIX II

OPPORTUNITIES WHICH ALL COMPANIES HAVE TO CONTROL ABSENTEEISM BY CARE IN VENTILATION

Introduction

Many theories have been advanced to explain the harmful effect of poor ventilation on the human body. So many factors enter into the question that a great diversity of opinion is possible. We may be certain, however, that bad ventilation does exert a profound influence on human health and comfort. The effect of ventilation on health and mental and physical aggressiveness should be as well recognized as is the effect of climate. The object of ventilation should be to maintain ideal atmospheric conditions indoors. While the food and water that we consume always receive attention, the condition of the air we breathe is too often left to uncontrolled whims of nature.

The changes in heating and ventilating necessary to keep pace with theory have been delayed by many factors. Most human beings have a natural inertia which opposes any change. In addition, we are fond of holding on to outworn ideas and discredited theories. Then, too, it is often the policy of manufacturers of apparatus to follow the line of least resistance, instead of keeping abreast of the latest developments.

Requirements of Good Ventilation

The normal chemical composition of the atmosphere is maintained with striking constancy under practically all conditions. This is made up as follows, by volume:

Nitrogen	78.10%
Oxygen	20.90%
Argon	0.90%
Carbon dioxide	0.03%
Insert gases other than argon	0.07%

While the chemical relation is maintained almost constant, atmospheric moisture and dust vary widely.

Of all the theories purporting to explain the effect of poorly ventilated air on the human body, one of the most widely held until recently was that of Pettenkofer. His theory was that the influence of bad air is due to the presence of toxic organic substances excreted into the atmosphere from the human body. It has now been proved that odor and bacteriological content are not harmful except where the air is specially polluted. However, an atmosphere laden with odors is objectionable on æsthetic grounds, if on no other. It now seems also that the influence of atmospheric dust on health depends, not on the gross amount of dust present, but on whether or not the peculiar kind of dust is harmful per se.

The problem of oxygen and carbon dioxide content need never worry us. Oxygen must fall to 16 per cent before important physiological reactions are involved. In the worst ventilated rooms, carbon dioxide rises only from 0.03 to 0.5 per cent, and this is still below the limit of physiological change.

The changes taking place in an unventilated room, as the result of human occupancy, may be summarized as follows:

1. Oxygen is reduced.
2. Carbon dioxide is increased.
3. Partially oxidized organic matter is given off.
4. Room temperature is raised by the heat liberated in the course of body oxidation.
5. Humidity is increased by the moisture given off in the breath and from the skin.

The first two changes may be dismissed from consideration, since it has been proved that they do not take place to such an extent as to affect the human organism. The harmful effects of organic matter cannot be substantiated, so we must look to the last two considerations for the illness due to bad air. Interference with the processes of body temperature regulation is the main point of discomfort.

In the human mechanism food and air are consumed and energy developed; because the body is inefficient in the delivery of energy for work, more heat is generated than is needed. Under normal conditions the human body develops over 300 B.t.u. of heat per hour. The excess heat is given off as:

1. Warm expired air.
2. Radiation from body surface.
3. Evaporation of perspiration.

In order to maintain temperature equilibrium, this heat must be eliminated. It has been found that the essential requirement of proper ventilation is the removal of this excess heat as it is developed. Therefore, the main requirement of a ventilation system is its cooling property. If the excess heat is not removed, the body temperature rises above the normal temperature of 98.6 deg., and discomfort, body disorders and even death may follow. The effect of this rise in temperature is dilation of the tiny blood vessels of the skin and pooling of the blood in these vessels. The consequent feeling of discomfort and lassitude is probably due to anemia of the brain and internal organs, due to this pooling of the blood in the capillaries.

It appears, then, that the essential criterion of an atmospheric condition is the net cooling effect which it exerts on the human body. This effect is determined by three factors: temperature of air; relative humidity, and movement of air. An ideal temperature for office work would be 66 to 68 deg., with about 50 per cent relative humidity. Small variations in humidity are unimportant. The third factor in ventilation is the extent to which radiation and evaporation are favored by the movement of air. In a still, warm atmosphere, the body is surrounded by a layer of hot and moist air. In order to promote radiation of heat from the body and evaporation of perspiration, this layer of air must be removed. However, too much air movement will produce drafts, a condition also injurious to the health.

To summarize, a good ventilating system will provide:

1. Temperature, 66 to 68 deg. fahr.
2. About 50 per cent relative humidity.
3. Air removal.

Effect of Poor Ventilation on Health

The New York State Commission on Ventilation has made an extensive laboratory study of the effect of overheating on health. These studies were conducted in two rooms especially equipped for the purpose at the College of the City of New York. One of these rooms was the observation room, which was insulated to prevent heat loss and exchange of gases through the walls. Heating and cooling coils were located within the room, and an elaborate system of ventilation made it possible to supply fresh air of any desired quality and quantity, or to recirculate the vitiated air of the room itself. The second chamber was the apparatus room and contained the fans, heaters and other apparatus necessary to control the atmosphere of the observation room and automatically record its condition. The experimenter manipulated valves and levers so as to expose the subject to various atmospheric conditions. The physiological reactions and mental and physical efficiency of the subject were constantly being studied, meanwhile, by physiologists and psychologists within the observation room itself.

These experiments were conducted almost continuously from December, 1913, to January, 1915. Squads of four subjects were usually used, and each experiment continued for as long a period as was necessary to obtain significant results. Altogether 113 persons were subjected to observation.

The chief atmospheric conditions studied were three in number:

1. 68 deg. fahr. with 50 per cent relative humidity.
2. 75 deg. fahr. with 50 per cent relative humidity.
3. 86 deg. fahr. with 80 per cent relative humidity.

The results obtained under these various conditions may be summarized, so far as physiological reactions are concerned, as follows:

First, the temperature of the body itself is slightly but definitely increased by a rise in atmospheric temperature. The average body temperature of the subject fell 0.8 deg. fahr. when exposed to the 68 deg. condition; it fell only 0.1 deg. when exposed to the 75 deg. condition; and it rose 0.2 deg. when exposed to the 86 deg. condition. The average final body temperature was 98.1 deg. at 68 deg. fahr.; 98.5 deg. at 75 deg. fahr., and 99.3 deg. at 86 deg. fahr.

The heart rate decreased markedly at 68 deg., but remained high at 75 deg. and 86 deg. The average final heart rates in the reclining position were 66 at 68 deg., 81 at 75 deg. and 74 at 86 deg.; in the standing position, 77 at 68 deg., 105 at 75 deg. and 99 at 86 deg. It is not certain whether the higher heart rate at 75 deg., as compared with 86 deg., is significant or not.

The most marked effect was that recorded by the Crampton Index, an arbitrary measure of the general efficiency of the circulation system. This measure is obtained by a comparison of blood pressure and pulse rate in the reclining and standing position. A high Crampton Index means that on standing up after lying down, the circulatory system is able to increase the blood pressure so as to meet the greater burden placed upon the system by erect posture without any marked increase in heart rate. A low index means that, on assuming an erect position, the heart beats much faster and that even then the blood pressure falls. In other words, it is a measure of the efficiency with which the circulation responds to a demand upon its power of adjustment. At 68 deg., the general average Crampton Index was 60; at 75 deg. it was 45; and 86 deg. it was 34. These results show a marked lowering of the efficiency of the circulating system with increased temperature.

The final symptom recorded was an increase in the rate of respiration, from an average of 17.9 at 68 deg. to 19.3 at 75 deg. and 19.7 at 86 deg.

The research laboratory maintained at Pittsburgh by the United States Bureau of Mines, the United States Public Health Service and the American Society of Heating and Ventilating Engineers has made a significant series of investigations in regard to the effects of more extreme overheating. The workers at this station equipped a carefully controlled experimental chamber which could be varied through a die range of temperatures, humidities and degrees of movement. Subjects in this chamber have been exposed to high temperature to the point at which a longer stay appeared definitely dangerous. The chief symptoms experienced were restlessness, irritability, headache, palpitation of the heart, soreness of the eyes, laziness and confusion. Weakness and a dragged-out feeling persisted for some time after such experiments had closed. The body temperature under prolonged heating rose several degrees. The pulse rate seemed to be the best measure of discomfort, 135 beats per minute corresponding to marked discomfort; and conditions becoming almost unbearable when the pulse rate exceeded 150 beats.

The results obtained under laboratory conditions are fully confirmed by practical experience. The unnatural conditions described above increase susceptibility to infection, and the resultant colds and respiratory diseases account for a large proportion of our absences from business.

Methods of Ventilation

The best method of ventilation or of cooling, to be employed in any particular case, can only be determined after careful analysis of accompanying circumstances and contributing factors. Each particular situation needs a separate solution.

Since the maintenance of a proper temperature, however, is the primary consideration in ventilating, no office room should be without a thermometer. This is probably the most important article of ventilating equipment, since it is impossible to consider ventilation without heating.

There are, in general, two types of ventilation, natural and artificial.

Natural ventilation operates to some extent even in closed rooms by heat loss through walls and ceiling. In crowded offices, however, natural ventilation is not likely to prove satisfactory. In warm weather temperature differences will provide an insufficient supply of air to remove either body odors or excess heat. On the other hand, in cold weather difficulties will be encountered as a result of inequalities of distribution. In a natural ventilating system, an outlet for warm air must be provided above and an inlet for cool air below. To properly use this system, continual watchfulness must be maintained over the outlet and inlet.

In offices special provision must usually be made for the removal of heated air and the supply of fresh cool air. Two methods are in general use:

1. Gravity Ventilation—Inlet and outlet openings are provided, but reliance for the movement of air is placed on the temperature difference between inside and outside air or chimney action.
2. Fan Ventilation—Inlet and outlet passage of air is forced by fan movement.

As a rough standard of ventilation requirements, 30 cu. ft. per person per minute may be set up. However, as heat conditions vary so much, any such standard is of necessity somewhat meaningless and must be changed to meet conditions. If the number of occupants of a room is not available, ventilating calculations may be carried out on the basis of the number of changes of air per hour over the whole room, which for the average office should be about six.

In using the method of gravity ventilation, choice in practice lies between fan supply with gravity exhaust and window supply with gravity exhaust. It has been found that a lower temperature is usually maintained in a window-ventilated room, but this room will be less perfectly aerated and will have less air movement. Fan ventilated rooms are apt to be drafty since the current of air moves more rapidly. The temperature in window-ventilated rooms is characterized by slight fluctuations and varies from 66 to 68 deg. fahr., while that in fan ventilated rooms varies from 68 to 70 deg. fahr.

Preference has been expressed for the window-ventilated room. It would appear then that coolness due to low temperature and relatively slight air movement is preferable to coolness produced by air motion in the presence of higher temperature.

If the window-supply gravity exhaust system is to be used, the following provisions should be made:

1. Radiators, equipped with automatic control, should be located beneath the window and extended for the full length of the window.
2. Deflecting boards should be placed at the bottom of the window.
3. Windows should open easily at the bottom.
4. Exhaust ducts should be placed on the wall opposite the windows, dampered so that the area may be adjusted to varying weather conditions. These exhaust ducts should be carried up through the middle of the building to avoid chilling. The tendency to back drafts may be further reduced by an aspirating cowl placed on the opening at the roof.

The choice between window and fan intake rests in general on two considerations:

1. Relative desirability of surrounding the body with a rapidly moving current of warmer air or a more moderate current of cooler air.
2. Relative cost of construction and operation of the two types.

In large crowded spaces, where little opportunity may be afforded for ventilation through the walls and ceiling, we must sometimes resort to fan ventilation. Two types of fan are in general use in forced ventilation:

1. Propeller
2. Centrifugal

The propeller fan operates on the principle of an ordinary desk fan, having curved vanes which drive the air at right angles to the general plane in which the fan itself revolves. This type will move considerable volumes of air, but only against low pressure. It is well adapted to supplement natural ventilation. However, this type is not suitable where air must be moved against considerable pressure, as in duct systems of ventilations.

For duct ventilation the centrifugal type of blower fan should be used. In this fan air is drawn in by lateral openings at the center of the plane of revolution and forced out through a tangential duct by the action of a series of parallel blades. This type may be used as either a plenum or an exhaust fan. It is used as a pressure or plenum fan when it delivers to the ventilating duct and draws in the supply freely from an air chamber. The centrifugal type may also be used as an exhaust fan, and the central opening is connected to the ventilating duct and the delivery is to the outer air.

The essential parts of a system of forced ventilation are the fan chamber, fans and ducts. From the fan chamber the air is delivered to the various parts of the building by a system of ducts carried up, through, or along the walls. These ducts must be so proportioned as to distribute the air evenly between the different parts of the building. Many systems of fan ventilation fail to give satisfactory results because the ducts are imperfectly proportioned. Also, even where the work is properly done, the system must be intelligently operated to secure the right results. Individual duct dampers should be provided so that the air supply to each room can be independently governed. It is important to secure equable distribution of air within the different parts of the room itself. Air velocity at room inlets should not be excessive, probably not over 300 ft. per minute. If it is desired to provide an air supply of 80 cu. ft. per person per minute, the inlet registers in any room should have a total area .of 0.1 cu. ft. per person.

Air conditioning is not completed by bringing in, distributing and removing an adequate supply of fresh outdoor air. However, this may improve previous conditions tremendously at a small cost, and that may be all that is practical. In almost all offices the expense of equipment to control air supply absolutely will not be justified. Variability is a recognized essential of an invigorating atmosphere. It might also be said that artificial humidification, while necessary to some manufacturing processes, does not seem to have an appreciable effect on human health and efficiency. Avoidance of overheating is the primary essential of good ventilation.

There are many schemes of ventilation on the market which embody slightly different principles. One of these is the recirculation system. This system may be used independently or as an adjunct of open-window ventilation. Recirculation requires a double system of ducts, which is somewhat of a disadvantage. The hot, odorous air is taken off the top of the room, while at the same time vent openings at the floor remove the cold air and recirculate it.

It is claimed that this method produces the required motion of the air without overheating. An automatic control must be installed on the surplus heat outlet, to determine the volume of air moved.

Unit ventilating is another special application of ventilation principles. Under this system the air comes directly from outdoors, is cleaned by air filter, heated and distributed. Each room is provided with a complete unit, making it unnecessary to run the entire ventilating system, if only a few rooms are in use. Each unit is provided with automatic temperature regulation. Then, if quick heating is desired, the fresh air damper may be closed, allowing the air of the room to circulate by gravity through the radiator. This system has been found satisfactory and economical in many cases.

In Conclusion

In conclusion, it might be said that "eternal vigilance" is the price of good ventilation. No system will work under all conditions without regulation. Its effectiveness will be influenced by wind velocity and direction, outside temperature, relative humidity and number of occupants of the rooms ventilated. A change in conditions will necessitate a change in area of duct or window opening, a different rate of heat supply, or attention to some other mechanical factor.

PUBLIC SPEAKING COMMITTEE

If a company is serving a public that is FRIENDLY and INFORMED, it is reasonable to assume that that company is enjoying good public relations.

The only ways ever devised by man by means of which these results can be secured is through Performance, The Spoken Word and The Written Word.

Of the eight committees comprising the Public Relations National Section of the National Electric Light Association, one is known as the Public Speaking Committee.

The Public Speaking Committee deals primarily in The Spoken Word, although, to a considerable extent, it deals in Performance and The Written Word.

If we think this matter through, we are forced to the conclusion that any company will achieve good public relations if it develops a well balanced program which includes the three factors mentioned above, namely Performance, The Spoken Word and The Written Word. Likewise any company will fall short of achieving good public relations if it omits or fails to take advantage of these factors in its program. Therefore, public speaking becomes a very important activity in our industry.

It is important from two points of view. Our business is a public service business, and we are public servants. Therefore, we are obligated to acquaint the public about the economic value of our services to them; of how they can use our service to the greatest advantage. Some of our leaders have gone so far as to claim that our service is incomplete to the extent that we fail to take advantage of our opportunities to inform. In any event, it is self-evident that we will never have an informed public unless we inform, and public speaking offers that opportunity.

The other great value to the industry from organized public speaking is the value that comes to the individual employee who participates in that activity. While many employees may be unable to qualify as effective public speakers, still it is a matter of great importance and of great value to the industry to have every employee take public speaking training. Briefly the value is this: As the employee takes the training, gradually over a period of time he learns to stand on his feet and think constructively. He can effectively tell what he knows about the subject under discussion. It means that the employee learns more about his business, becomes more efficient, has a larger vision of his opportunities and his possibilities and his responsibilities, and this is reflected in his every contact with customers and friends. Public speaking training with this object in view will do as much to achieve good public relations as any activity any company can engage in.

In studies that have been made, it has been proved beyond any question of doubt that the impression the employee makes on the mind of the customer is twice as strong as all factors combined in determining the customer's estimate of the service. In other words, the impression left by contact with meter readers, collectors, telephone clerks, cashiers, sales people, complaint clerks, and so on, was twice as important as the promptness, dependability, efficiency and all around physical quality of the service itself.

Because public speaking activities are of such great importance, both to our customers and to our employees, it has been the purpose of this committee to encourage these activities, not only persistently and continuously, but to encourage our companies to carry on this work in a systematic, business-like way.

Two meetings of the committee were held last year, one in New York with an attendance of nineteen, and the other in Chicago with an attendance of twenty-six. At these meetings two important phases of work were engaged in. The first was the revision of our Handbook. This has since been published in two forms. The loose-leaf form intended for the use of executives and all who are active in public speaking. The other is a paper coveed book known as "The Electric Light and Power Industry in the United States."

While these books have not received as large a circulation as we could wish, it has been fairly generous. Thousands of copies have been placed with member companies, libraries, newspaper offices and the like. This book, with which many members are familiar and all should be, contains a total of twenty-three chapters. They cover:

History
The Electrical Industry and Research
Finances of the Electric Light and Power Industry
Customer Ownership
Regulation
Electric Rates
Cost of Manufacture and Ultimate Delivery
Steam Power
Water Power
Electricity in Industry
Electricity in the Home
Lighting
Meters
Rural Electrification
The Romantic History of Local Transportation
Advertising
National Statistical Survey
The Gas Industry
Radio Broadcasting
Public Speaking
Visual Education
Outline of Supplementary Facts on the Industry
Bibliography

In addition, the talks given at the Public Utility Conference at Grand Beach, Mich., in August, were included, as follows:

"Public Utility Information Bureaus" by H. M. Lytle, Vice-President, Chicago Rapid Transit Company.
"The Gas Industry," by B. J. Mullaney, Vice-President, The Peoples Gas Light & Coke Company.
"Street Railways," by A. W. Robertson, President, Pittsburgh Railways Company.
"Financing the Utilities," by Martin J. Insull, President, Middle West Utilities Company.
"Fallacies with Regard to the Utilities," by Howard T. Sands, Vice-President, Electric Bond & Share Co.
"Holding and Management Companies," by Halford Erickson, Vice-President, Byllesby Engineering & Management Corporation.
"State Regulations of Public Utilities," by William J. Hagenah, Vice-President and Special Counsel, Byllesby Engineering & Management Corporation.

Publication No. 289-77, Serial Report.

"Interconnection," by George N. Tidd, President, American Gas & Electric Company.

The Handbook is a real encyclopedia and can be used advantageously as a source of information for talks. In addition to that it can be used to great advantage as a text book in employee educational meetings.

To indicate what some thought of it, the committee wishes to quote what Mr. P. S. Arkwright, President of our Association and President of the Georgia Power Company, wrote us about it:

> "The Georgia Power Company has thought well enough of this book to purchase sufficient copies to place them in the hands of all of our officials and department heads. We have also made them available to interested employees. Copies also have been supplied to a number of our larger customers, libraries and similar organizations outside the company. We consider this worthwhile as a means toward educating our own employees and the public generally as to the true facts about the industry."

Another letter from Mr. E. G. Green, Educational Director, Oklahoma Gas & Electric Company, Oklahoma City Okla., the company of which Mr. J. F. Owens, Chairman of the Public Relations Section and Vice-President of N. E. L A., is Vice-President and General Manager, indicates their reaction:

> "We are finding the new N. E. L. A. HANDBOOK so valuable as a text and reference book in our public speaking classes in the Oklahoma Gas & Electric Company, that I feel prompted to write to you a word of appreciation, as chairman of the Public Speaking Committee of the National Electric Light Association, under whose direction the book was compiled.
>
> "In our advanced public speaking class, which we call the Public Speaking Forum, we have adopted the Handbook as a study text and an outline for the course of thirteen sessions. The chapters have been distributed over the period, and the student-members of the class secure their material from the chapter assigned for each meeting. Results have been excellent. We feel that this method not only informs the students regarding the electrical industry, but it also furnished them with good subjects for talks before the class and in other places.
>
> "Our work is not designed to train actors and Chautauqua orators, but rather to afford practice to the members of this company in straight business talking, such as may be used in committees, conferences, civic clubs, and the like.
>
> "And I feel that the chief element in the success of the course is the consistent use of the Handbook. Every public utility man should study it as the young men and women of the class to which I have referred are doing. It is a valuable contribution to the business."

These are but two of numerous letters that were received.

The other work engaged in by the committee this year was to develop a statement of Policies and Plans covering the purposes and scope of the public speaking committee and to work out a system of report. This statement follows:

Statement of Policies and Plans of the N. E. L. A. Public Speaking Committee

1. PURPOSE AND SCOPE—The purpose of the Public Speaking Committee is to assist in the dissemination of facts regarding the electric light and power industry primarily to employees and to qualify employees to address other groups when requested. It is axiomatic that employees well informed regarding the industry for which they work render better service to their employees and the public than those who are not, and that public speaking is an effective means of self-development. It is felt that much misunderstanding is caused by lack of understanding of facts, or by misinformation. A duty devolves upon those in the industry because of its quasi public character to provide and make available reliable, accurate and timely information.

   The scope of the committee, therefore, is to organize through the Geographic Divisions a bureau of public speakers, dealing with subjects pertaining to the electric light and power industry, and to assist in the training of employees of the industry so that they may present facts regarding the industry through the spoken word.

2. ORGANIZATION—The Public Speaking Committee recommends that a thorough plan of organization be perfected throughout each Geographic Division.

3. COMMITTEE ORGANIZATION—The Chairman of each Geographic Division automatically becomes a member of the National Committee. In addition there are several members-at-large. We recommend that the Chairmen of the Geographic Divisions perfect a similar committee whereby the chairman of each state would automatically become a member of his committee in addition to the appointment of several members-at-large; and that the state chairmen in turn organize the state in whatever manner is deemed most practicable.

4. EXECUTIVE RESPONSIBILITY—The executive of each operating company is directly responsible for public speaking activities within his territory, and in order to make any plan a success it should be understood that the individual operating company executive must be thoroughly informed of and interested in the plan before he will give it his unqualified cooperation and support to the extent of instructing his organization that this work is vitally important in rendering complete service to the public.

5. COOPERATION—In order that there be no duplication in organization set-up, there should be a very close cooperation with all public speaking organizations functioning at this time, such as those fostered by State Committees on Public Utility Information. Every possible effort should be made to make these public speaking organizations sufficiently broad to include the gas, electric railway and telephone industries.

6. SUGGESTIONS—After such an organization is perfected, any or all of the following may be undertaken:

   (a) *Lists of Speakers*

   Compile lists of experienced speakers now available, accompanied by detailed information concerning their experience, abilities, availability, etc.

   (b) *Lists of Organizations*

   Compile lists giving detailed information of all business organizations, clubs, schools and other organized groups throughout each Division, as it is helpful to know what organizations are liable to want speakers for regular programs.

   (c) *Development of Speakers*

   In order that an adequate number of speakers be developed, this committee recommends that executives, in cooperation with public speaking committee representatives, establish training classes in charge of competent instructors, wherever practicable to do so. In the larger centers this can be accomplished through employee educational meetings and regular classes; in the more scattered districts by means of employee meetings and two-day schools, which usually are held at some central point where operating companies adjacent to that point may send employees selected because of their possible public speaking abilities, the instructor giving an intensive two days' instruction. Such schools may be repeated from time to time. As rapidly as speakers develop proper ability they are given assignments.

   (d) *The Value of Public Speaking Training to the Individual*

   Undoubtedly the greatest benefit in training employee personnel in public speaking is the effect of such training on the individual employee.

   When the average employee is approached with a view to his training in public speaking, the immediate reaction is that he cannot do it, but after he has been tried out in a typical employee educational meeting, the possible benefits begin to appear.

There is created a desire to know not only about his individual job, but all jobs. He wants to know about the history and operation of his industry, about the laws under which it is operated and his responsibility to the public served.

In response to this desire to know, one sees the individual employee beginning to read and to study and to think as never before. His thinking is constructive and his thoughts crystallized.

Over a period of time he becomes conscious of additional knowledge and this additional knowledge gives him additional power, confidence and poise. He applies his increased knowledge to his daily tasks. He becomes more efficient. He exercises greater care in his personal appearance. He produces more and as a result the public receives a better and more satisfactory service.

As he is called upon to express his ideas and thoughts, either informally before individuals or formally before groups, he expresses himself accurately, correctly, courteously and effectively. Such contacts result in satisfied, pleased customers.

All of this, then, means that the relationship between the company, as represented by its employees, and the public, whom we serve, will be more pleasant and satisfactory, and to the individual employee it means a larger, more useful and happier life.

(e) *Filling Assignments*

Great care should be used in filling assignments. Only those should be sent who are really qualified and have a message for the particular group. Likewise, care should be exercised that repetition of messages be reduced to a minimum.

It is a matter of importance to the industry to know whether or not those who fill assignments are satisfactory to their audiences. A speaker is not necessarily a good judge. Comments received from the audience or from the secretary of the organization are liable to be only courteous expressions. It is well for executives in the community where the talk is made to attend the meeting, study the audience and the speaker in order to estimate the character and value of the address and to make an official report. This procedure is recommended wherever practicable.

When a speaker appears before an audience, it should be made clear under whose auspices he appears, and whom he represents. Any printed copies of the talk, or newspaper releases, should give the same information, and likewise the issuing source of copies or releases should be stated.

(f) *Subject Matter*

It is recommended that all speakers carefully observe the "Outline of Points and Facts which the Utility Industry wishes placed before the Public," as published by the association in August, 1927. All speakers not familiar with this outline should secure a copy directly from the N. E. L. A. Headquarters. Generally speaking, subjects of facts should be discussed and controversial subjects avoided. Subjects falling within the classification of civic and industrial development, economics, history, manufacture and distribution, rural electrification, safety and service can be made instructive and intensely interesting. Visual helps, such as motion picture films, slides and charts, can often be used advantageously.

The responsibility of speakers for accuracy of statement is emphasized. The information used by them should be from authentic sources.

While the use of skits and sketches, musical numbers, films (Unaccompanied by lectures) or other entertainment features, demonstrations and cooking schools cannot be classed as public talks, still they have value. All such activities should be encouraged.

(g) *Records*

To systematize our work, it is recommended that the following records be kept:

First: The Speakers' Record Card
Second: The Organization Record Card

The Speakers' Record Card would indicate the groups before whom a particular speaker appeared, subjects he discussed and the approximate audience in each case. The Organization Card would indicate what speakers have appeared before that organization, their subjects and the approximate audience in each case.

With such a record, the one responsible for making the assignments can always determine when a utility speaker appeared last before a particular group, what his subject and earlier subjects were, who the speakers were and thus be able to avoid duplication.

(h) *Publicity*

It is always a courteous thing for a speaker to prepare, well in advance, several paragraphs covering the high spots of his talk. These should be sent to the utility executive in the particular community several days in advance in order that it may be available if newspaper men wish to print articles regarding the meeting.

(i) *Reports*

A system of reports is recommended so that every talk before a public group will be reported by the local company in the particular town, through organization channels, to State, Division and National Committees.

These reports should be made monthly to the State and Geographic Division Organizations and annually to the National Organization. (See Fig. 1 and 2.)

(j) *Plant Visitation*

It is recommended that, where it meets with the wishes of the operating company, the speaker, or the utility executive, who presumably introduces him, use the opportunity to invite the public groups to visit local utility plants.

7. N. E. L. A. HANDBOOK—The Handbook is ready for distribution. It is recommended that this Handbook, which is in reality a text book for the industry and which is larger and more complete than ever before, can be used effectively by member companies, not only for public speaking purposes, but for employee educational meetings as well. We furthermore recommend that it be made available to anyone interested.

With such a statement every member company, knowing what the National Association desires in the way of information, can make provision in its organization for the keeping of these records, so that as requests are made from time to time through organization channels, it will be able to send to those who are appointed to carry on this work complete, accurate information.

The actual reports for this year are gratifying. A total of 36,887 talks to a total audience of 4,629,926, or 5603 talks to 764,456 more people than were reported in the last previous report.

A comparison of these activities for 1928 and 1927 by geographic divisions and States is shown in Table I.

CONCLUSION

In conclusion the committee chairman wishes to express his appreciation for the splendid support and assistance he has received from the committee.

FIG. 1—ANNUAL REPORT FORM.

As committee meetings have been called, the members have generously responded and have given of their time, money and effort in helping to make this work successful.

As in previous years the officers and members of the staff at headquarters have been of great help, for all the members of the committee, like its chairman, are engaged in specific activities in the field, and as publications or reports are undertaken by the committee, the burden of editing and publishing falls upon headquarters. Our committee has nothing but praise for Mr. George F. Oxley, the Director of the Department of Public Information, who never fails us. The Geographic Division officers, even more than in former years, have generously supported the program recommended by the Committee.

FIG. 2—MONTHLY REPORT FORM.

While there are still a few who do not appreciate the importance of this activity, their numbers are growing fewer, and as our executives are becoming better acquainted with the possibilities of this work, of its value in their respective organizations and its value to the public, and as they realize that the more both customers and employees are informed, the more harmonious and satisfactory their relations are going to be, just naturally the more this work is going to be done, so for next year we predict that there will be more and better talks throughout the entire country.

ADDENDUM

ELECTRIFICATION OF STEAM RAILROADS

Program of the Committee

The Committee on Electrification of Steam Railroads adopted a definite program in 1926 which it was foreseen would require several years to complete. During this period the program should be repeated each year as the keynote of the Committee's activity:

1. To study railroad electrification in a general way, avoiding technical details.
2. To analyze railroad electrifications already made and to develop the fundamental reasons for, and the results of, these electrifications.
3. To promote cooperation between the executives of railway and power companies in order to develop a clearer understanding of each other's problems and requirements in connection with railroad electrification.

An understanding of this program will make clear the viewpoint of the Committee and the object of its studies.

Work of the Year

The Committee continued to maintain an office in Chicago as described in the 1928 report. The membership has been slightly increased to better represent the different interests involved, until there are at the end of the year 27 members. They represent four general divisions as follows: eleven from railroad companies, eleven from power companies, three from manufacturing companies and two consulting engineers.

Several members of the Committee are members of similar committees of other technical associations, thus providing a certain amount of cooperation and interchange of information. It is hoped that some time a plan may be worked out for greater correlation of the work of these various committees whereby overlapping of activities may be decreased. One of the good reasons for such an arrangement is to lessen the calls made upon the railroads for information and statistics.

The Committee maintains a large file of descriptive data and statistics for the preparation of its annual reports and statistical summaries. It also furnishes general information on steam railroad electrification to persons and companies who are interested in such research.

Exhibit at Chicago

On Nov. 15, 1928, the Electric Association of Chicago held its annual dinner meeting at which cooperation with the railroads was the keynote. President Crowley of the New York Central Lines made the address, and extracts from his remarks are given herewith in Appendix C.

This meeting was largely attended by railroad and central station executives from all over the country. Many members of this Committee attended in a group. The Committee prepared a special edition of its 1928 Report for distribution at the meeting, and an exhibit of the progress of electrification which is illustrated in Fig. 1. On the left of the exhibit was a panoramic view of the Virginian Railway, which was described in the report being distributed. On the right of the exhibit was depicted the present ex-

Publication No. 289-118, Serial Report, Electrification of Steam Railroads Committee.

tent of electrification. All the electrified sections were shown on a large paneled map of the world, with photographs inserted to illustrate the types of motive power used in the United States.

Subcommittees

This year for the first time two subcommittees were appointed on "Electrification in Europe" and "Standard Form of Contract." The Subcommittee on Electrification in Europe made a trip through the principal countries of western Europe and submitted a report which is appended hereto. The Subcommittee on Standard Form of Contract made a study of the contracts now used in this country for the sale of energy to electrified railroads. From this study they have outlined the desirable features to include in such a contract. The report of this subcommittee is also appended.

Statistical Tables

Statistics of electrical installations by steam railroads in the United States and all other countries are given in Table I, "Condensed Analysis of Installations of Electrical Operation on Steam Railroad Lines." This table is practically complete for the end of the calendar year 1928 and summarizes all the installations made since the beginning of electrification in 1895. Table II, "Physical Characteristics of Operation on Electrified Sections of Steam Railroads," presents summaries of the electrical equipment, traffic and energy for the United States, Canada and Mexico, and for all other countries and railroads from which the statistics have been received.

Recent Progress of Electrification

The past year has seen the extension of many electrifications and the purchase of considerable additional equipment, in the way of locomotives and motor cars. Several sections which had been in process of construction for some time previous were turned over to electric operation. Several railroads are known to have taken bids on initial electrifications, but the new projects announced in the past year were mostly by roads that had already some electrification.

United States

Since the last report of the Committee three electrifications have been completed. There have also been several important announcements with regard to other installations now in progress or planned for the future.

Boston, Revere Beach & Lynn R. R.

The Boston, Revere Beach & Lynn Railroad has completed the electrification of its narrow-gage system. Electric operation was commenced in October, 1928. An overhead contact line of simple-catenary construction is used for direct current at 650 volts.

Great Northern Railway

The Great Northern Railway has finished the installation work in its new Cascade Tunnel so that complete electric operation began on Jan. 12, 1929. This electrification has been described in previous reports. As one result of the new tunnel, the previous electrification, which was restricted to an older and shorter tunnel, has been replaced by an 8-mile tunnel and an electric division about 75 miles in length. Electric locomotives haul the regular freight and passenger trains by means of single-phase power from an overhead contact line energized at approximately 11,000 volts.

Pennsylvania Railroad

The Pennsylvania Railroad has completed the electrification of additional suburban routes in its Philadelphia district. The new services are from Philadelphia to Chester and Wilmington, and from Philadelphia to Media and West Chester. On Oct. 31, 1928, this company announced the authorization of a very large new project which covers the passenger and freight service on 325 miles of line and 1300 miles of track. When this improvement is completed, about 1937, the Pennsylvania Railroad and subsidiaries will have a total of nearly 2300 miles of track operated entirely with electricity. The full text of the announcement is copied in Appendix C of this report.

Reading Company

The Reading Company, on Nov. 12, 1928, made formal announcement of its plans for electrification in the vicinity of Philadelphia. The first stage of electrification will embrace only the suburban service, but it is intimated that probably extensions will be made to New York, Bethlehem and Reading. The length already authorized is 49.5 miles of route with 110 miles of track. Multiple-unit trains will be run from a single-phase 11,000-volt contact line (similar to the Pennsylvania Railroad's system in the same territory). The complete announcement is repeated here in Appendix C.

Delaware, Lackawanna & Western R. R.

The Delaware, Lackawanna & Western Railroad has selected for its suburban electrification near New York 3000-volt direct current with overhead contact line. Multiple-unit cars will be used. Some new equipment for this voltage has been built by one of the electrical manufacturers and is now undergoing tests at its works. This will be the first installation in this country of 3000-volt direct current on multiple-unit coaches. It is reported that one reason for selecting this voltage is its adaptability to main-line operation in the future.

Cleveland Union Terminals Co.

The Cleveland Union Terminals Co. has arranged to purchase power for its electric zone from the Cleveland Electric Illuminating Co. This electrification will utilize direct current at 3000 volts. There will be two substations owned by the railroad and equipped with 3000-kw. motor-generator sets. One substation will have a capacity of 6000 kw. and the other 9000 kw. The substations will be automatic, unattended, and operated by synchronous supervisory control. It is planned to have this new development in service by the early part of 1930.

Lehigh Valley Railroad

The Lehigh Valley Railroad is reported to be making estimates on the cost of electrifying its main line between Mauch Chunk and Wilkes-Barre, Pa. About 75 miles of double track is involved.

Illinois Central Railroad

The Illinois Central Railroad, which has been operating its suburban passenger service by electricity since 1926, has ordered 4 electric locomotives for freight switching in the Chicago Terminal division. These locomotives will be delivered in 1929. They will weigh 100 tons each, with a one-hour rating of 1465 h.p. The power supply will be 1500-volt direct current from overhead contact line, the same as the suburban service.

The Illinois Central is also using for freight switching an oil-electric locomotive weighing 100 tons, and will make service tests of a combination locomotive weighing 85 tons. The latter is a self-charging storage-battery unit that can be run either with or without a contact line. It is of the type called "general purpose locomotive," with all weight on drivers, and intended primarily for switching service. It can operate directly from a contact line at 750 or 1500 volts, or can run on power from the battery. The battery may be charged in two ways, either from the contact line through a motor-generator set, or by means of two small oil-engine generating sets.

Foreign Countries

The principal countries of Europe are covered by the report of the Subcommittee on Electrification in Europe. Progress in other countries of the world is described in the following paragraphs.

Argentina

The Central Argentine Railway was authorized, in January, 1929, to proceed with the extension of its suburban electrification which now extends from Buenos Aires to Tigre via Victoria. The new project includes the line from Buenos Aires to Tigre via Coghlan and the line from Coghlan to Villa Ballester, a total of 26 miles. The project also involves doubling the power station capacity, and the addition of automatic substations with supervisory control.

The Central Terminal Railway of Buenos Aires is constructing 5½ miles of double-track subway penetrating the main business district of Buenos Aires. This construction contemplates that the passenger trains of the Buenos Aires Central Railway will operate through the subway from the present terminal to a new passenger terminal to be constructed within the business district.

Australia

The New South Wales Government Railways are engaged in converting to electric traction the remainder of their large suburban services at Sydney. Electrification of two principal lines to the north and the south suburban districts was completed in 1927. Electrification in the western suburbs has been carried as far as Homebush during 1928. It is expected that the change-over will be all finished in 1930, comprising about 400 track miles.

Belgium

It is reported that the Brussels-Antwerp line of the Belgian State Railways is to be electrified. The distance is 30 miles. This will be the first electrification of main-line railways in Belgium.

Brazil

Since 1921 the Paulista Railway has been steadily engaged in the extension of its electrified zone. In September, 1928, the road inaugurated electrified service from Rio Claro to Rincao, 95 miles in length, making a total of 179 route miles operated by electricity. Plans now in hand call for the electrification, and widening to their normal gage of 63 in., of the sections from Rincao to Porto Cemiterio, 145 miles in length, and the branch from Ityrapina to Jahu, a distance of 108 miles.

Egypt

The Egyptian State Railways have had under consideration for some time the electrification of a suburban line from Cairo Terminus to Helwan, a distance of 16 miles. Tenders for the conversion were opened in February, 1929, and it is expected that the work will be completed in about eighteen months. The objects are to improve and speed up the service and to cause development of the territory. Economy is also expected from better ability to accommodate the service to the needs of traffic.

Hungary

The Hungarian Government is reported to have negotiated arrangements for construction of a large power development in the brown coal district. One of the objects is to make available electric power for electrification of the principal trunk railway between Budapest and the Austrian frontier near Vienna.

India

The Great Indian Peninsula Railway has been progressively electrifying a considerable part of its system since 1925. From Bombay to Kurla and Bandra was completed in 1925 and early 1926. The main line from Bombay to Thana was completed in 1926, and from Thana to Kalyan in 1928.[1] Work is now in progress on two divisions from Kalyan to Poona and from Kalyan to Igatpuri respectively. The whole project covers some 180 miles of route, with 1500-volt direct current, and using both locomotives and motor cars.

---

[1] Latest extension not yet included in Table I.

TABLE

CONDENSED ANALYSIS OF INSTALLATIONS OF EL

Name of Railroad	Location	Electric Mileage			System of Electrification Installed			
		Route	Main Track	All Track	Volts	Phases	Cycles	Contact Line

GENERAL NOTES

D.C.—Direct Current.
O.H.—Overhead
3R—Third Rail.
4R—Four Rails.

The dates in column entitled "Year Electrified" are for the placing in operation of the original electrification and of the most recent important addition thereto.

UNITED STATES
A—Originally overhead; changed to third rail in 1901.
B—Old Cascade Tunnel electrified with 3-phase in 1909; changed to 1-phase and extended in 1927; new tunnel with extension opened in 1929, and old tunnel abandoned.
C—Operates on tracks of New York Central.
ARGENTINA
E—Overhead contact line in Port Zone for locomotive operation.
AUSTRIA
L—550 volts, direct current, in city of Vienna.

: I

ECTRICAL OPERATION ON STEAM RAILROAD LINES

Year Electrified	Traffic Affected	Reasons for Electrification	Results of Electrification
1895	Freight and Passenger	Eliminate smoke in tunnel	Capacity increased; operating costs lowered; smoke eliminated.
1925	Suburban Passenger	Legislation; tunnel operation; terminal switching	Facilities increased; operating economies.
1911	Freight and Passenger	Increase capacity; eliminate smoke in tunnel	Tunnel operation facilitated; capacity increased.
1928	Suburban Passenger	Reduce operating costs; increase efficiency of service	Reduction of headway; use of fewer scheduled cars.
1913	Freight and Passenger	Increase capacity; general economy	Fewer trains, fewer delays; increased tons per train, annual saving.
1915–1916	Freight and Passenger	General economy; increase capacity; heavy grades; tunnels	Capacity increased; traffic increased; operating econ's.
1919–1920	Freight and Passenger	General economy; increase capacity; heavy grades; tunnels	Capy. increased; traffic increased; operating economies.
1915	Freight Switching		
1926	Freight Switching	City ordinance; eliminate smoke	Smoke eliminated.
1926	Freight	Increase facilities; eliminate smoke; Detroit city ordinance	Smoke eliminated; efficiency increased.
1907	Passenger	Increase capacity	Capacity and facilities increased; economy.
1906–1912	Freight and Passenger	Increase facilities; reduce operating costs	Operating costs reduced; facilities increased.
1927–1929	Freight and Passenger	Decrease operating costs; eliminate smoke in tunnel; increase speed of trains	
1926	Suburban Passenger	Increase facilities; eliminate smoke; agreement with Chicago	Higher speed; more trains accommodated; increased patronage.
1905–1926	Freight and Passenger	Improve suburban service; facilitate terminal operation; tunnels; legislation	Smoke eliminated; facilities increased; faster service.
1927	Freight	To facilitate through freight operation with N.Y., N.H. & H.R.R.; also legislative requirement	Smoke eliminated; economies in handling through traffic
1910	Freight and Passenger	Eliminate smoke in tunnel	Capacity and speed improved; operating economies.
1906–1926	Passenger	Operation through tunnel; improve service; increase facilities	Smoke eliminated; capacity increased; air rights developed.
1895	Passenger	Increase traffic by improved service	Service improved and traffic increased.
1901	Passenger	Increase traffic by improved service	Service improved.
1907	Passenger	Legislation prohibiting steam operation in tunnel; terminal operation; increase facilities	Facilities increased.
1907–1914	Freight and Passenger	Increase facilities; general economy	Facilities increased.
1908	Freight and Passenger	Increase facilities; general economy	Facilities increased.
1925	Freight and Passenger	Increase facilities; general economy	Facilities increased.
1918–1927	Freight and Passenger	Increase facilities; general economy	Facilities increased.
1912	Suburban Passenger	Increase facilities	
1915–1925	Heavy Freight	Grades; tunnels; increase capacity	Capacity increased; operating economies.
1906	Passenger	Increase traffic by improved service and facilities	Revenue increased by increased traffic; oper'g economies.
1910	Passenger	Legislation; tunnel; new terminal in New York	
1915–1924	Freight and Passenger	Suburban traffic; congested terminal	Terminal capacity increased.
1928	Suburban Passenger	Suburban traffic; congested terminal	Terminal capacity increased.
1911	Passenger	Increase facilities; eliminate smoke	
1925	Heavy Freight	Increase capacity; heavy grades; tunnels	Increased capacity; reduced fuel and operating costs.
1923	Suburban and Freight	Improve service; increase capacity; tunnel operation	Traffic increased by improved service and capacity increased.
1916	Suburban Passenger	Better service with faster schedules	Capacity increased; faster schedules; general economy; increase in traffic.
1926–1928	Suburban Passenger	Increase capacity	
1919–1923	Suburban Passenger	Increase facilities; general economy	
1907	Freight and Passenger	Increase capacity; grades; tunnels; conserve fuel; use water power	Operating economies; increased facilities.
1912	Freight and Passenger		
1912	Freight and Passenger		
1914	Freight and Passenger	Increase traffic	Traffic increased.
1924	Freight and Passenger	Tunnels and heavy grades; utilize water power	
1925–1927	Freight and Passenger	Increase capacity; tunnels and heavy grades; conserve fuel	Smoke eliminated; capacity increased.
1927	Freight and Passenger	Increase capacity; tunnels and heavy grades; conserve fuel	Smoke eliminated; capacity increased.
1928	Freight and Passenger	National policy; conserve fuel	
1925	Passenger	Agreement in lease-contract with city	Smoke eliminated.
1905	Freight and Passenger	To shorten ascent and use average grade of 6.5 percent	Reduction in running time; fuel economy.
1921–1926	Freight and Passenger	Coal scarcity; heavy grades; increase capacity	Capacity increased; operating economies.
1928	Freight and Passenger	Coal scarcity; heavy grades; increase capacity	
1927	Freight and Passenger	Heavy grades; conserve fuel

	Usui Line: Yokogawa, Karuizawa (I)	6.90	6.90	13.40	650		D.C.	3R.
	Tokio, Ofuna, Kozu, Atami & Ofuna, Yokozuka	101.28	222.15	299.51	1,500		D.C.	O.H.
Yoshino Railway	Yoshino, Yoshinoguchi	7.20			1,500		D.C.	O.H.

CHILE

D—Will operate in unison with electric traction of Argentine Transandine when the latter road has completed its electrification. Combined rack and adhesion on electrified section.

FRANCE

F—Electrification started in 1910 with 12,000 volts, 1 phase, 16 2/3 cycles. Approximately 70 miles were electrified but have since been changed to 1500 volts d-c.

G—First electrification made in 1900-1904 from Paris to Juvisy with 600 volts d-c. Changed to 1500 volts in 1924.

ITALY

Mileages electrified by Italian State Railways in Table I are for end of 1928, but in Table II are for year 1927.

JAPAN

H—Part of Tokio city, circle and suburban system.

I—Combined rack and adhesion on electrified section.

(*Continued*)

ECTRICAL OPERATION ON STEAM RAILROAD LINES

Year Electrified	Traffic Affected	Reasons for Electrification	Results of Electrification
1908	Freight and Passenger	Grades; smoke in tunnel; increase capacity	Capacity increased 100%; tunnel operation improved.
1918–1927	Freight and Passenger	Operation in tunnel and residence section	Tunnel operation facilitated; capacity increased.
1922	Freight	Increase capacity	Capacity increased; smoke eliminated; better efficiency in winter.
1927	Freight and Mixed	Heavy grades; difficult to obtain water; high cost of fuel	Increased speed and tonnage; lower costs.
1916	Freight	Heavy grades; scarcity of water	
1926	Freight	Reduce operating costs	Cost per ton-mile greatly reduced.
1924	Freight and Passenger	Increase capacity; heavy grades; scarce coal	Capacity increased; operating economies.
1927	Freight and Passenger	Heavy grades; tunnel operation; expensive fuel	Capacity increased; smoke eliminated.
1914	Freight and Passenger		
1920	Freight and Passenger	Grades; high cost of fuel	
....	Freight and Passenger	High cost of fuel	
1903	Freight and Passenger	Increase capacity; conserve fuel	
1928	Freight and Passenger	Tunnel operation; eliminate smoke	
1910–1928	Freight and Passenger	Increase capacity and speed on heavy grades	Capacity increased; fuel saved.
1925	Freight and Passenger	Heavy grades; long tunnels; plenty of water power	Capacity increased; fuel saved.
1900–1924	Freight and Passenger	Increase capacity and facilities; reduce consumption imported coal	Capacity increased; annual coal consumption reduced.
1900–1928	Passenger	Improve service; increase capacity.	Traffic increased by improved service and increased capacity.
1900	Passenger	Long grade; tunnel about 2 miles long	Satisfactory.
1914–1928	Freight and Passenger	Grades; congestion; use local coal	
1922–1927	Freight and Passenger	Use brown coal not suitable for steam locomotives	
1912–1928	Freight and Passenger	Utilize water power	
1908–1909	Freight and Passenger	Utilize water power	
1913	Freight and Passenger		
1916	Passenger	Heavy grades	
1911	Freight		
1908–1924	Suburban Passenger	Increase capacity; eliminate smoke; general economy	
1924–1928	Suburban Passenger	Increase capacity; eliminate smoke; general economy	
1903	Suburban Passenger	Increase capacity; eliminate smoke; general economy	
1924	Freight and Passenger	Experiment with electric traction	
1928	Suburban Passenger		
1925–1926	Suburban Passenger	Heavy suburban passenger traffic	
1926	Suburban Passenger	Heavy suburban passenger traffic	
1901–1902	Suburban Passenger	Heavy suburban passenger traffic	Excellent.
1902	Freight and Passenger	Tunnels; grades; conserve coal; use water power	Excellent.
1914	Freight and Passenger	Tunnels; grades; conserve coal; use water power	Excellent.
1911–1928	Freight and Passenger	Tunnels; grades; conserve coal; use water power	Very satisfactory; capacity and traffic increased; operating economy.
1912–1924	Freight and Passenger	Tunnels; grades; conserve coal; use water power	Very satisfactory; capacity and traffic increased; operating economy.
1925–1927	Freight and Passenger	Improve service; long new tunnel under city	
1927	Freight and Passenger	National policy; conserve coal; use water power	
1927	Freight and Passenger	National policy; conserve coal; use water power	
1928	Freight and Passenger	National policy; conserve coal; use water power	
1929	Freight and Passenger	National policy; conserve coal; use water power	
	Freight and Passenger		
	Freight and Passenger		
1929	Suburban Passenger	Increase capacity; improve service; bus competition	
1921	Freight and Passenger		
1922	Freight and Passenger	Heavy grades	
1908	Passenger	Increase capacity	Capacity increased.
1909–1928	Passenger	Increase capacity	Capacity increased.
1904–1922	Passenger	Increase capacity	Capacity increased.
1912	Freight and Passenger	Increase capacity; tunnels; heavy grades	Capacity increased; tunnel operation facilitated.
1925–1928	Freight and Passenger	Increase capacity	Capacity increased.
1922–1923	Freight and Passenger	Heavy grades	

TABLE I—

CONDENSED ANALYSIS OF INSTALLATIONS OF EL

Name of Railroad	Location	Electric Mileage			System of Electrification Installed			
		Route	Main Track	All Track	Volts	Phases	Cycles	Contact Line
MEXICO:								
El Potosi Railway	El Potosi Mine, Morse Smelter	14.91	17.39	18.64	600	.....	D.C.	O.H.
Mexican Railway	Esperanza, Orizaba, Paso del Macho	64.00	64.00	70.23	3,000	.....	D.C.	O.H.
MOROCCO:								
Moroccan Railway	Sale, Casablanca, Kourigha	158.46	158.46	....	3,000	.....	D.C.	O.H.
NETHERLAND EAST INDIES:								
Java State Railway	Tandjong Priok, Batavia, Meester Cornelis	24.85	56.00	75.00	1,500	.....	D.C.	O.H.

	London Suburbs: Central section (P)	30.00	....	108.00	6,600	1	25	O.H.
VENEZUELA:								
LaGuaira & Caracas Railway	LaGuaira, Caracas	22.68	22.68	24.85	1,600	.....	D.C.	O.H.

NETHERLANDS

U—The line Rotterdam—The Hague—Scheveningen was electrified in 1908 with 6600 volts, single-phase, 25-cycles, changed in 1926 to 1500 volts d-c.

NORWAY AND SWEDEN

J—The line Narvik—Riksgrensen, in Norway with the line Riksgrensen—Kiruna—Lulea, in Sweden, form a unified system from the Atlantic to the Gulf of Bothnia.

SWITZERLAND

K—Transformation to 15,000 volts. 16 2/3 cycles, has been prepared.

UNITED KINGDOM

M—First electrification made in 1913 from Bury to Holcombe Brook with 3000-volt d-c. Changed to 1200 volts in 1916.

N—On London, Tilbury & Southend Line and operated jointly with the District Railway. No figures for the District Railway's operations are included in the Tables.

O—Operated jointly with the Metropolitan Railway.

P—The former London, Brighton & South Coast Railway electrification with 6600-volt a-c. is being gradually changed to 650-volt d-c., like the Southern Railway, of which it is now a part.

Q—Also operated over with jointly owned stock between Queens Park and Watford. No figures for this operation included in Table.

(*Concluded*)

ECTRICAL OPERATION ON STEAM RAILROAD LINES

Year Electrified	Traffic Affected	Reasons for Electrification	Results of Electrification
1925	Freight............	Capacity; grades; regeneration; economy........................	Capacity increased; operating economies; greater safety and reliability.
1924–1927	Freight and Passenger	Heavy grades; conserve fuel....................................	Operating economies; service more satisfactory.
1927	Freight and Passenger	Scarcity of coal and of good water for steam; plenty of water power; benefit of regeneration....................................	Higher speed; increased capacity; economy.
1925–1926	Suburban Passenger..	Conserve fuel by using water power..........................	Faster schedules.
1908–1927	Passenger...........	Increase capacity of road and stations........................	Capacity and traffic increased.
1924	Freight and Passenger	Heavy grades; five-mile tunnel................................	Capacity increased; smoke in tunnel eliminated.
1929	Freight and Passenger	Tunnel operation..	
1923	Freight and Passenger	To provide unified operation with Swedish line Lulea-Riksgrensen	Capacity increased
1922	Freight and Passenger	National policy; save coal; use water power......................	
1927	Freight and Passenger	National policy; save coal; use water power.....................	
1911	Freight and Passenger	Use water power..	
1912	Freight and Passenger	Cheap water power from associated industries..................	Favorable.
1908	Freight............	Heavy grades; high cost of fuel................................	
1924	Freight and Passenger	Heavy grades; sixteen miles of tunnels; increase capacity..........	Capacity multiplied about three times.
1929	Freight and Passenger	Increase traffic by improved service............................	Satisfactory.
1929	Freight and Passenger	Increase capacity and speed..................................	
1926	Freight and Passenger	Eliminate smoke in tunnel and subway terminal station...........	Smoke eliminated; faster service.
....	....	....	....
1915–1923	Freight and Passenger	Save fuel; use water power....................................	
1925–1926	Freight and Passenger	Save fuel; use water power....................................	
1908–1915	Freight and Passenger		
1921	Freight and Passenger	Reduce transportation charges.................................	Most favorable; operating costs reduced; capacity increased.
1916	Passenger...........		
1910–1927	Freight and Passenger	Utilize available water power; long heavy grade; tunnel 9 miles long.	
1920–1923			
1899	Freight and Passenger	Increase capacity; conserve fuel..............................	
1919			
1903			
1910	Passenger...........		
1901	Freight and Passenger		
1913–1922	Freight and Passenger	Save coal; heavy grades; increase capacity......................	Operating costs reduced.
1924			
1906	Freight and Passenger	Heavy grades; tunnel; save coal; use water power...............	
1910			
1918–1928	Freight and Passenger	National policy; save coal; use water power; increase capacity......	Coal conserved; operating economies; better service work provided for industries during post war depression.
1926	Freight and Passenger	Increase capacity over heavy grades...........................	Reduction in running time; better service.
1927–1928	Suburban Passenger..	Increase capacity..	Capacity increased; service improved.
1906	Suburban Passenger..	Increase capacity..	Capacity increased.
1920	Suburban Passenger..	To provide for working in tubes; increase capacity................	Capacity increased.
1914–1927	Suburban Passenger..	Develop suburban traffic......................................	Greatly increased residential traffic.
1905–1908	Suburban Passenger..	Enable through operation of Metropolitan Ry. trains.............	Traffic increased.
1904–1913	Suburban Passenger..	Tramway competition; increase capacity.........................	Capacity, speed and service improved; traffic increased
1916	Suburban Passenger..	Tramway competition; increase capacity.........................	Traffic increased.
1908	Passenger...........	Develop traffic..	Service improved.
1904	Freight and Passenger	Improve service in effort to increase traffic.....................	Traffic increased.
1915	Freight............	Great density of traffic......................................	Capacity increased.
1903	Passenger...........	Tunnel; grades; heavy expense.................................	Business increased; operating economies.
1915–1925	Suburban Passenger..	Increase traffic; increase capacity.............................	Increase in traffic.
1925–1929	Suburban Passenger..	Increase traffic; increase capacity.............................	Increase in traffic.
1909–1925	Suburban Passenger..	Increase traffic; increase capacity.............................	Increase in traffic.
1928	Freight and Passenger	Expensive fuel; heavy maintenance of steam locomotives..........	Economy; faster service; greater capacity.

GENERAL NOTES

Length of All Track electrified includes Main Track, Yard and Siding Track in electric zone (so far as equipped for electric operation).

Ruling Grade refers to grade against heaviest traffic and to curves on this grade.

Ratings of Locomotives and Cars owned, due to condensing for tabulation, are given for the largest type only of each kind. Horsepower and Tractive Effort are the one-hour ratings.

Average Number Trains Daily is number run in both directions.

Figures expressing length have been converted to (1) the English Foot, and (2) the Mile of 5280 ft.

Figures expressing weight have been converted to (1) the Pound Avoirdupois, and (2) the ton of 2000 lb. This applies likewise to the Ton-Miles and Kilowatt-hours per Ton-Mile.

TABLE II—PART I—(*Concluded*)

PHYSICAL CHARACTERISTICS OF OPERATION ON ELECTRIFIED SECTIONS OF STEAM RAILROADS

SPECIAL NOTES

a—Passenger and Freight Locomotives
b—Electric service one direction only
c—Measured at Locomotive
d—Placed in service during year 1928.
e—Operates on tracks of New York Central
f—Included in Woodlawn—New Haven Section
g—Summer service only
h—Regeneration not computed
i—Power sold to other companies
j—Information from technical journals
k—Electric operation of isolated freight yard
l—Power purchased from other railroads
m—Train miles
n—Estimated for 1928
o—Per 1000 ton-miles passenger service
p—Freight and passenger service
q—Net ton-miles
r—Main line division only
t—High tension at Power **Station** or Substation
v—Approximate figure by test
x—For six months, June—November, 1927
z—Placed in service during year 1927. Equipment included in section Innsbruck, Feldkirch, Bregenz
S—Standard railroad equipment
T—At train
P.S.—At Power Station
S.S—At Substations

The South Indian Railway has been authorized by the Railway Board to electrify suburban sections in the vicinity of Madras. A proposed scheme for much more extensive electrification is said to depend on the development of sufficient water power.

Japan

In 1928 the Japanese Government Railways completed electrification on the Atami line from Odawara to Atami. About 13 miles was equipped with overhead contact line at 1500 volts, direct current.

Morocco

More complete information has been received regarding the electric operation of the Moroccan Railway, inaugurated in 1927 on about 160 miles of single-track line. Electric trains now run between Casablanca and Kourigha and between Casablanca and Sale. The reasons were scarcity of coal and of good water for steam, abundance of water power, and the possibility of very advantageous use of regenerative braking on heavy mineral trains brought down grade toward the coast. The change to electricity is said to have resulted in a great expedition of traffic.

The system chosen is 3000-volt direct current, from overhead contact line, with locomotives for freight trains and multiple-unit trains for passengers. Twenty-six locomotives were purchased, of two slightly different types, each approximately 80 tons weight, 1400 h.p., 37 miles per hour. The locomotives are arranged for multiple-unit operation and for regenerative braking. The freight cars used here are of the large capacity of 53 tons.

The motor cars are 73 tons weight, 700 h.p. and 53 miles per hour. Each has four motors and seats 64 persons. The two motors on each truck are connected in series across the line voltage. The motor cars are also equipped with multiple-unit control but not for regenerative braking.

New Zealand

In February, 1929, the New Zealand Government Railways inaugurated electric operation between Christchurch and Lyttleton on the South Island. The length is 6.33 miles, which includes the Lyttleton Tunnel. An overhead contact line is energized with direct current at 1500 volts. Six 50-ton locomotives were installed and one automatic substation containing rotary converters with supervisory control. This is the second short electrification on this system within the last five years.

Union of South Africa

The South African Railways completed, in 1928, the electrification of two lines, namely, Capetown to Sea Point and Capetown to Simonstown. The length of the first is 3.65 miles and of the second 23 miles. These lines furnish principally suburban passenger service. Multiple-unit trains operate with 1500-volt direct current from an overhead line. Energy is furnished by the Electricity Supply Commission's power station which is interconnected with the Capetown Municipal power station.

From Capetown to Sea Point the line is single-track and carries 180 trains per day for express and local service. From Capetown to Simonstown it is double-track as far as Fish Hoek (18.7 miles) and carries 211 trains per day with 18 train-sets. The equipment consists of 83 motor coaches, 37 driving trailers and 95 plain trailers.

Proposed Activities

The work already planned for next year, in addition to the regular statistical studies, includes (1) a continuation of the preparation of a standard form of contract for sale of energy to electrified railroads, and (2) a special report on the electrification of steam railroads including data on the capital cost of several typical installations.

APPENDIX A

REPORT OF SUBCOMMITTEE ON ELECTRIFICATION IN EUROPE

The Subcommittee, composed of four members, sailed from New York the latter part of October and landed in England early in November. After traveling through England and around the Continent, they sailed from Southampton at the end of the year and arrived in New York the first week of January. Eight weeks were spent in Europe.

ITINERARY AND PLACES VISITED

The itinerary is shown by Fig. 1. Seven countries were visited: England, Netherlands, Sweden, Germany, Switzerland, Italy and France. In addition to visiting most of the steam railroad electrifications in these countries, the rapid-transit subways were inspected in London, Berlin and Paris. Numerous generating stations supplying energy for railroad traction were visited, both hydraulic and steam stations, also substations and converting stations for making the energy suitable for railroad purposes.

The principal cities, railroads, power companies and manufacturing plants which were visited in each country are as follows:

England

Underground Electric Railways of London.
  Lines, generating station, overhaul shop, signal school.

NOTE 1—Weights and distances have been expressed as tons and miles, the ton consisting of 2000 pounds. Horse powers have not been changed due to the slight difference between the metric and the foot-pound ratings. Electrical units are of course the same in all countries.

NOTE 2—Locomotive horsepower is intended to be expressed as the one-hour rating. Some capacities which were given orally may vary from this method, although the effort has been made to check all ratings by books and technical articles.

SUBCOMMITTEE ON ELECTRIFICATION IN EUROPE ITINERARY NOV.-DEC. 1928.

FIG. 1—MAP OF ITINERARY.

Southern Railway Co., London district.
 Lines, generating station, signal and interlocking plants, and car shops.
London, Midland & Scottish Railway Co.
 London district: Lines, generating station, substations, signal and interlocking plants, and car shops.
 Liverpool district: Lines and generating station.
 Manchester district: Lines and substation.
London and North Eastern Railway Co.
 Newcastle district: Tyneside electrified lines.
 Shildon district: Electrified mineral line.
Newcastle-upon-Tyne Electric Supply Co., Ltd.
 Office building, power stations, low-temperature carbonization plant.

The Netherlands

Netherlands Railways, Amsterdam and Rotterdam.
 Lines and substations.

Sweden

Swedish State Railways.
 Stockholm: Offices, locomotive inspection shop, electrification Stockholm-Gothenburg.
 Hallsberg: Special cars for contact-line inspection and repairs, substation.
 Motala: Private factory of A.-B.Lindholmen-Motala, building electric locomotives for the Government Railways.
 Orebro: General overhaul shop.
 Gothenburg: Locomotive inspection shop.
 Trollhattan: Private factory of Nydquist & Holm A.-B., building electric locomotives for the Government Railways.
Swedish State Power System.
 Motala: Hydraulic generating station.
 Trollhattan: Hydraulic generating station and canal system.

Germany

German General Electric Co., Berlin.
 Locomotive factory near Berlin.
 Factory making mercury arc rectifiers and railway motors.
Siemens-Schuckert Co., Berlin.
 Departments making electrical equipment for railways and for power generation.
Berlin Elevated and Underground Railways.
 Lines and substations.
Berlin City Electric Co.
 Klingenberg generating station.
Bavarian Power Co.
 Walchensee hydroelectric generating station.
Kreuzeck Railway.
 Aerial cableway near Garmisch.
German Government Railways Co.
 Berlin district: Offices, and electrification of City, Circle and Suburban Railway including substations and overhaul shop.
 Silesian district: Electrification Breslau-Gorlitz and branches, overhaul shops at Hirschberg and Lauban, substation at Hirschberg.
 Bavarian district: Offices, overhaul shop and substation at Munich; electrified sections, Regensburg-Munich, Munich-Salzburg, Munich-Garmisch.

Switzerland

Swiss Federal Railways.
 Berne district: Mechanical and electrical departments, inspection shops, communication circuits, substations; electrified lines, including Berne - Lausanne - Martigny, Berne - Delemont, and Berne-Zurich; Vernayaz hydraulic power station.
 Zurich district: Main shops at Zurich; substations at Olten, Rupperswil and Gruze; electrified line Zurich-Chiasso, including St. Gotthard tunnel.
 Simplon Route: Electrified line from Iselle (Italy) to Brigue, including Simplon tunnel, and from Thun to Berne.
Bernese Alps Railway (Loetschberg Line).
 Electrified line from Brigue to Thun, including Loetschberg tunnel.
Manufacturers in Zurich District:
 Brown Boveri & Co.
 Oerlikon Co.
 Swiss Locomotive & Machine Works.
 Sulzer Brothers.
 Escher Wyss & Co.
Hydroelectric Generating Stations.
 Muhleberg Station of Bernese Power Co.
 Fully Station of West Swiss Power Co.
 Olten-Goesgen Station of Olten-Aarburg Electric Co.

Italy

Italian State Railways.
 Milan district: Electrification Monza-Lecco. and shops.
 Florence district: Principal locomotive depot, and electrification Florence-Pistoia.
 Rome district: General offices, locomotive shops, electrification Rome-Tivoli, and substations.
 Naples district: Electrification Naples-Villa Literno, electrification Benevento-Foggia and substation.
 Genoa district: Electrification Genoa-Ronco and substation, Genoa Harbor development, private steam generating station supplying part of railway energy.
North Milan Railway, Milan.
 Office, substation, shops and electrification in process for suburban service.
Manufacturers at Milan:
 Pirelli Cable Works.
 Societa Officine Meccaniche.

France

Metropolitan Railway of Paris (Underground).
 Lines and car shops.

Paris, Lyons & Mediterranean Railway.
  General Offices at Paris.

Paris-Orleans Railway.
  Offices, substations, locomotive shops and electrified lines for suburban service, at Paris; and electrification Paris-Orleans.

State Railways of France.
  Offices, car shops, electrified suburban lines, all in or near Paris.

Midi Railway.
  Paris: General Offices.
  Tarbes: Motive Power Department.
  Electrified Lines: Bordeaux-Tarbes and Pau-Canfranc (Spain), including substation at Lourdes.

Electrical Manufacturers.
  Constructions Electriques de France at Tarbes: Electric locomotives and power generating equipment.

Electric Power Companies.
  Two steam generating stations at Paris belonging to private companies and involved in the supply of power to railroad and underground lines: the North Station of the Cie. Parisienne de Distribution d'Electricité, and the Gennevilliers Station of the S. A. Union d'Electricité.

ELECTRIFICATION IN COUNTRIES VISITED

A short description will be given of the railroad electrification in each of the countries visited. Preceding this description is a table of general statistics for the seven countries visited and for three adjoining ones. This table indicates the size of each country and the extent of railroad development. For ease of comparison by the American readers, similar figures for the United States are also given.

A great amount of information was secured on the trip which cannot be included in this report without making it unduly long. Consequently, in accordance with the Committee's policy of studying electrification in a general way, only the most general information has been included here.

GENERAL STATISTICS FOR THE UNITED STATES AND EUROPEAN COUNTRIES

*Includes England, Scotland, Wales and Northern Ireland.
**Total of passenger cars, trucks and buses.

Much material of a more detailed character has been placed in the Committee's files—including notes, reports, maps, monographs, magazines and manufacturers' descriptions of equipment. Such articles, for instance, as relate to costs of installation and of operation cannot be used in this country without first receiving very careful analysis of a specific nature not justified for a general report. All the data will be retained for office reference and for consultation by other organizations properly interested in the subject of railroad electrification.

England

At the beginning of 1923 all the principal railroads in England were, for the purpose of general operating economy, consolidated by act of Parliament into 4 large systems. The new systems are the successors to 123 separate railways that formerly operated the same lines. Prior to the consolidation there had been installations of electric traction on several of the existing railways. These installations had been made principally for suburban service or for experiment. They were of various types and of both alternating and direct current. Some of the consolidated systems thus found themselves possessed of 2 or 3 different types of electrification.

Since the consolidations some of the electrified lines have been changed over to the type preferred by the present owner. There has also been a general attempt on the part of the Government to cause adoption of a standard system of electrification for the whole country. Three reports by committees functioning under the Ministry of Transport have been made in 1920, 1921 and 1928. The last report was issued while the Subcommittee was in London.

The reports of 1921 and 1928 both favor direct current. The last one recommends the "maximum standard voltages" of 750 and 1500, at the substation, for third rail and overhead contact line, respectively. A higher pressure of 3000 volts is recommended to be permitted in certain cases by spe-

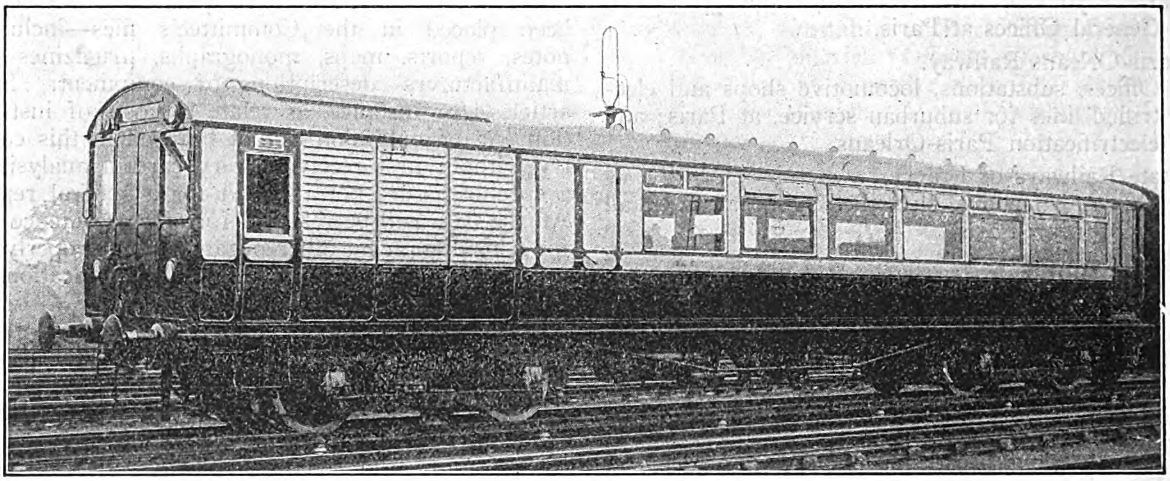

FIG. 2—LONDON, MIDLAND & SCOTTISH RAILWAY—MOTOR CAR FOR LONDON SUBURBAN SERVICE.

cial approval. There are various other recommendations relating particularly to motor voltages and to clearances, having in view the greatest facility for interrunning.*

Electrical operation at present is confined almost wholly to passenger traffic in the vicinity of some of the large cities. In the London area there is some joint running between the electrified sections of the steam railroads and the Underground Railways. The electrifications of the 4 large systems will be discussed individually.**

Great Western Railway

The Great Western has 2 short sections of line electrified in the London area. Each is about 5 miles in length. Both lines use a contact rail at pressure of about 600 volts. Electric operation is partly joint with the Underground Railways.

London, Midland & Scottish Railway

The L. M. S. has 4 sections electrified for passenger service at London, Liverpool, Manchester and Lancaster. Each will be described in turn.

This company has some very interesting electrical installations, several of which are quite new. Among the ones visited mention should be made of the large automatic substation at London, the 1200-volt substation at Manchester and of new signalling and interlocking installations at both London and Manchester.

London Electrification

The London suburban service on certain lines out of Euston Station was electrified in 4 stages between 1914 and 1922. About 42 miles of line and 90 miles of track are involved. The contact rail is supplied with direct current at 600 volts, and a fourth rail makes an insulated return circuit. Power is generated in the railway's power station at Stonebridge Park, adjacent to its car shops. There are 5 turbines with a total capacity of 30,000 kw. The energy is transmitted by cables at the generator pressure of 11,000 volts to 11 converter stations, which are also equipped with storage batteries.

The rolling stock consists of 99 motor cars and 182 trailers. First and third class accommodations are provided. The cars are compartment type with side doors for each compartment. This type of car seems to be preferred for commuting in the metropolitan area. Multiple-unit control is used, with driver's cabs on all the motor cars and on some of the trailers. The cars are large, well equipped and comfortable riding.

There is in addition to the service from Euston Station a short electrification, about 5 miles in length on the other side of London. This installation was made about 1905 and also uses third rail, but the energy is purchased from one of the electric power companies.

There is some joint running arranged for the Underground Railways on both the east and west side electrifications. There is also steam operation over the electrified tracks for other passenger and freight service.

Liverpool Electrification

Frequent electric passenger service is furnished in an extensive district north of Liverpool. There are about 38 miles of line and 93 miles of track. Electrification was done progressively between 1904 and 1913 with third rail at 600 volts. First and third class accommodations are provided. Freight is handled over the same tracks by steam locomotives, mostly at night.

The equipment includes 93 motor cars and 120 trailers. The old rolling stock has wooden bodies, but in 1927 four 6-car trains of steel cars were added.

The old cars are run in 5-car trains consisting of a motor car at each end and 3 trailers between. There is one driver's cab at each end of the train for direct control, power being cabled through the train to the motor car at the rear end. Cars have end entrances and center aisles. The motor cars weigh 54 tons and trailers 30 tons. Each motor car is equipped with four 150-horsepower motors, 600-volt. Vacuum brakes are used.

---

* It is anticipated that main-line trains may run from the 1500-volt lines onto the 750-volt terminal sections.

** There is also a separate short railway at Liverpool, called the Mersey Railway, which has been electrified since 1903. This railroad crosses under the River Mersey by a long tunnel and was quite difficult to operate by steam.

The new steel cars are made up into 3-car sets, each consisting of motor car, trailer and driving trailer. Two sets are operated as a 6-car train. Each motor car is equipped with four 240-horsepower motors, 600-volt.

Power is generated in the railway's power station at Formby with capacity of 22,000 kw. Twenty-five cycle energy is transmitted at generator pressure of 7500 volts to converter stations where it is fed to the contact rail. Storage batteries are also installed in some substations. An interesting feature is the use of a fourth rail for return current placed between the running rails and bonded to them.

The patronage on this line has grown to the limit of facilities and reconstruction of substations and distribution system is being considered. The power station has recently been completely overhauled and modernized by much new equipment. The rolling stock and roadway are well maintained and in very satisfactory condition. Consequently the cars ride well and the service is an asset to the territory.

Manchester Electrification

The line from Manchester north to Bury and Holcombe Brook was electrified in 1914 with 1200-volt contact rail. It is the only high-voltage third rail used in England. A specially constructed and protected side-contact third rail is used. There are about 14 miles of line and 30 miles of track.

Energy is supplied by the railway's power station at Clifton Junction with capacity of 10,000 kw. Three-phase power at 25 cycles is fed to 2 substations at generator pressure of 6600 volts. Each substation contains 1200-volt rotary converters and a large battery of the same voltage. It is customary to give the battery a boosting charge for about 30 hours per week at night and on Sunday. The battery does 3 cycles of work per day, handling the peaks of morning, noon and evening. This is due to an intermediate peak at midday occasioned by a long nooning which permits many riders to travel home to lunch.

There are 38 motor cars and 28 trailer cars. Cars are all steel with end entrances and center aisles. They are run in trains of 3, 4 or 5 cars. Control is of multiple-unit type with 2 driver's cabs for each car, and a small room for control switches at one end of each motor car. The motor cars are equipped with four 200-horsepower motors of 1200 volts each, giving a maximum speed of 60 miles per hour.

Control and lighting are at 120 volts supplied by a rotary transformer on each motor car. Heating is done with 1200-volt electric heaters. Vacuum brakes are used. The railway built the cars and 1200-volt motors in its own shops, but purchased the control equipment. The operating officials state that they are well satisfied with the operation of this line.

Lancaster Electrification

In 1908 the first single-phase electrification in the country was accomplished on about 10 miles of line between Lancaster, Morecambe and Heysham. Power is supplied by an overhead line energized at 6600 volts, 25 cycles. The power has been generated by the railway in a station adjacent to the line near Heysham. Beginning in 1929, power will be purchased from the local power system at Lancaster.

The motor cars have 2 motors each, of either 150 or 180 horsepower. A main transformer on each motor car reduces the line voltage for the motors, and an auxiliary transformer supplies the lighting. The control is multiple-unit type. The motor cars weigh about 45 tons and the trailers 20 tons.

North Eastern Railway

The North Eastern Railway is not electrified in the London area, but has 2 electrified sections in the north of England. One in the Tyneside district adjacent to Newcastle furnishes passenger service with multiple-unit trains. The other, in a coal mining district a little south of Newcastle, uses electric locomotives for handling the mineral traffic.

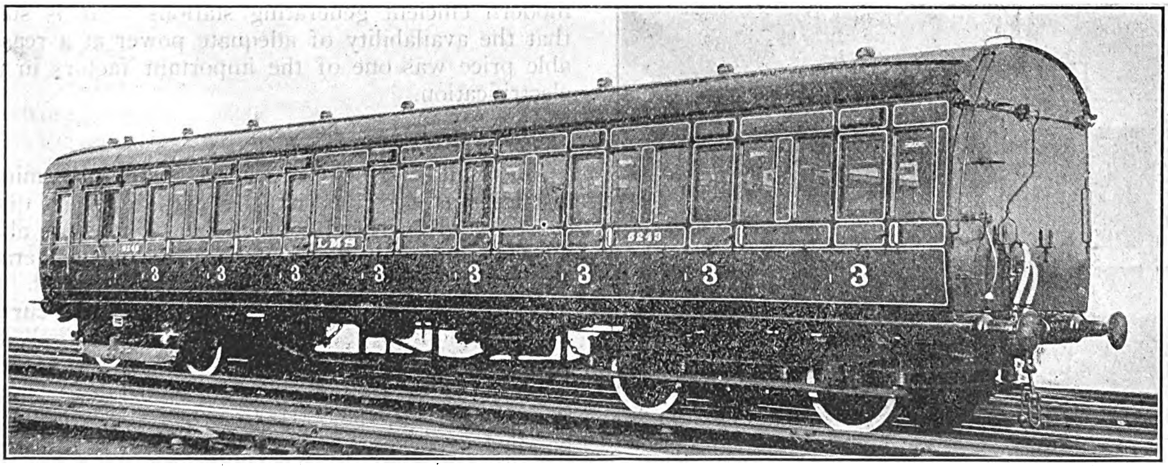

FIG. 3—LONDON, MIDLAND & SCOTTISH RAILWAY—DRIVING TRAILER FOR LONDON SUBURBAN SERVICE.

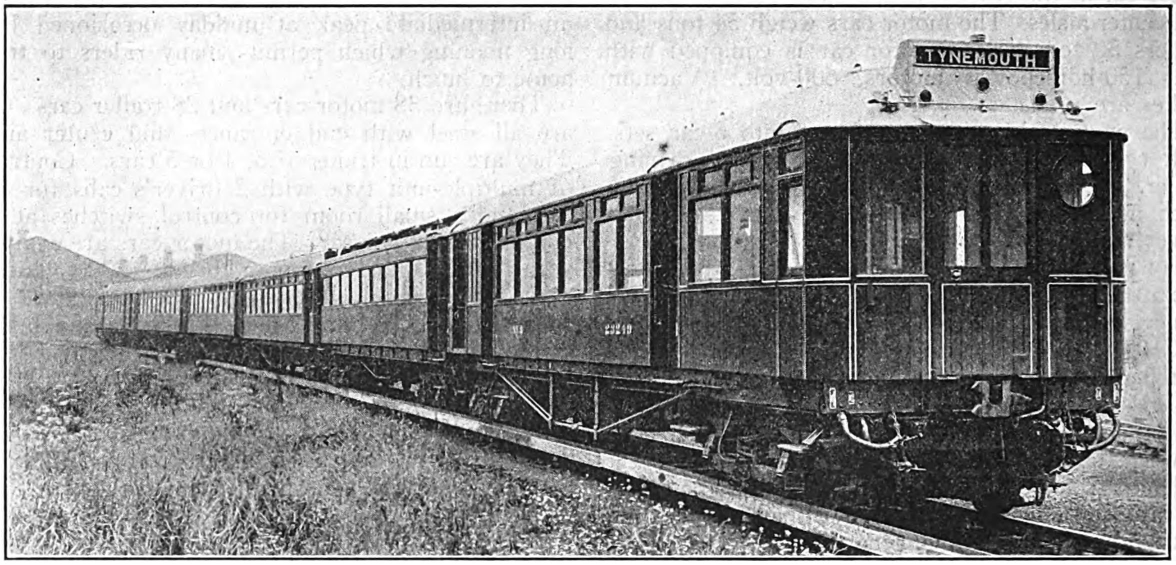

FIG. 4—LONDON & NORTH EASTERN RAILWAY—MULTIPLE-UNIT TRAIN FOR TYNESIDE ELECTRIFICATION.

Tyneside Electrification

The Tyneside electric service was inaugurated in 1904 through residential and heavy industrial districts about the River Tyne between Newcastle and the sea. There are about 32 route miles and 80 miles of track. First and third-class accommodations are provided with end-entrance center-aisle cars.

This line was electrified to meet tram and interurban competition. The results were very successful, and the growth of population, in addition, made a large increase in the passenger business. During the last few years there has been severe competition from highway buses, but this has been met by more frequent service. On the most traveled section there is now a train every 10 minutes.

The rolling stock is mostly the original equipment bought in 1904. The cars have wood bodies finished in natural teak. They are well fitted inside and have been kept in very good condition. They are grouped in 2-car units, for operation usually as 4-car or 6-car trains, although there are some 3-car units, including baggage cars. There is one motor car in each unit, and all cars are equipped for multiple-unit control, although some trailers do not have driver's cabs.

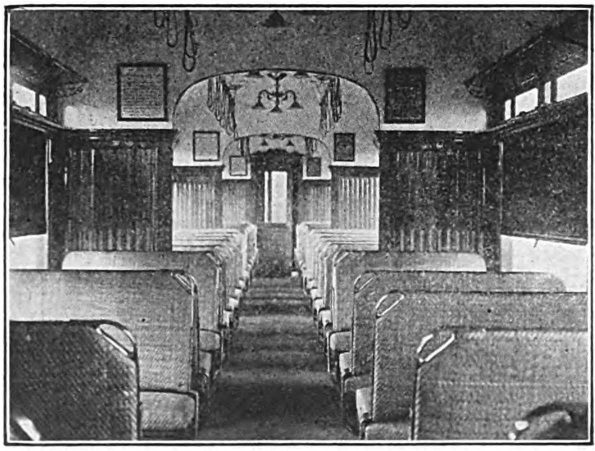

FIG. 5—LONDON & NORTH EASTERN RAILWAY—INTERIOR OF CAR FOR TYNESIDE ELECTRIFICATION.

Each motor car has one driving truck, or motor bogie, fitted with two 150-horsepower motors, each 600-volt. The motor cars weigh 34 tons and seat about 50 people in cars having both first and third-class accommodations, or 68 if entirely third class. The trailers, of somewhat varying design, weigh 22 to 25 tons and seat 68 or 72 persons, third class.

Power for the Tyneside electrification is furnished by the Newcastle-upon-Tyne Electric Supply Co., principally from its Carville generating station on the electrified line. This power company was a pioneer in the development of an interconnected network, covering a large territory and supplied by modern efficient generating stations.* It is stated that the availability of adequate power at a reasonable price was one of the important factors in this electrification.

Shildon-Newport Electrification

The Shildon-Newport section, in the coal mining district, was electrified in 1915 with 1500-volt direct current and overhead contact line. There are about 19 route miles of double track, and a considerable amount of yard trackage electrified at each end. The voltage is the highest used by any direct-current electrification in the country. It is also the only line to use electric locomotives excepting a few locomotives used for special switching purposes. During the year 1927, 53,000,000 gross ton-miles were handled.

The overhead is of the double catenary type with two contact wires, and suspended from steel latticed

---

*This power company is also noted for its interconnection with iron and steel plants, including the utilization of waste heat for generating electric power.

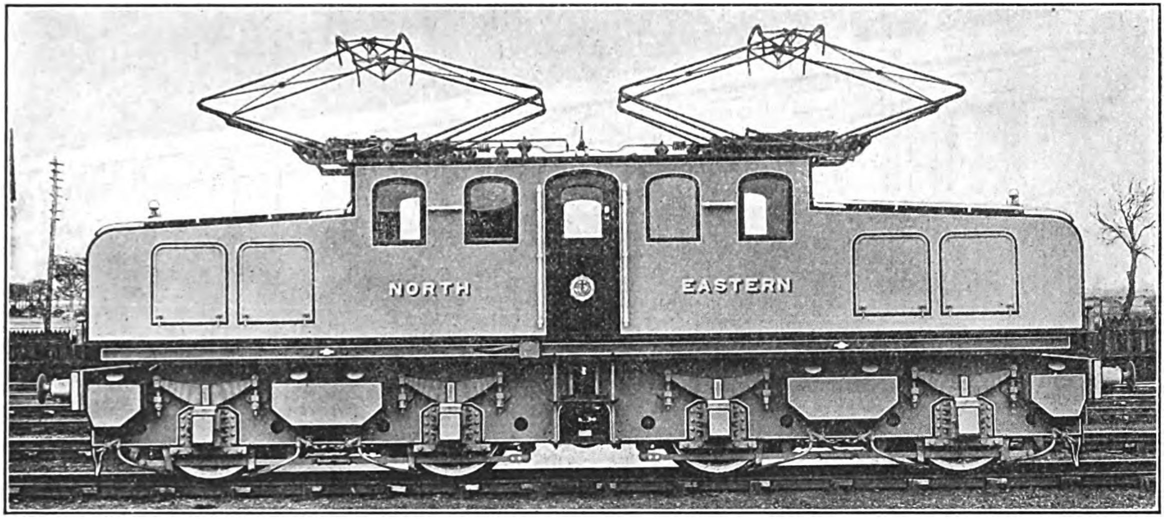

FIG. 6—LONDON & NORTH EASTERN RAILWAY—LOCOMOTIVE FOR SHILDON-NEWPORT ELECTRIFICATION.

structures. Counterweights are used for tensioning the contact wires. Pantagraph collectors are used on the locomotives. There are 10 locomotives weighing about 75 tons each and having wheel arrangement B + B. They have a free-running speed of 45 m.p.h., and were designed to haul trains of 1400 tons at an average speed of 25 m.p.h. The starting tractive effort is 28,000 lb.

The motors are nose-suspended and rated at 275 horsepower each. There are 4 motors on each locomotive, the motors being wound for 750 volts, with the 2 motors of each truck connected permanently in series. Acceleration may be manual or automatic. The locomotives were built in the railroad's locomotive shops using electrical equipment purchased outside.

Power is purchased from the local power company, which is part of a large interconnected system. Three-phase energy at 20,000 volts is taken into the railway substations and converted to direct current. There are 2 substations equipped with rotary converters connected as sets of two in series to give 1500 volts.

Southern Railway

The Southern Railway has at London the largest suburban passenger electrification in the world. While the electric traction in itself is not unusual, the traffic situation is very complicated. Added to large peak loads, originating on many lines over a wide territory, is a feature of multiple terminals with the attendant problem of providing access to each terminal for the trains to and from London over each and every route.

The reasons impelling electrification of the Southern Railway are largely related to traffic and improvement of service. In the first place, some twenty years ago, the constituent railways of the present Southern system found themselves losing much traffic to competing urban carriers. This caused them to turn to electrification as a help in retaining their patrons. Some lines were actually electrified, and others were planned but did not reach the stage of construction prior to the War.

After the Armistice, work was resumed under somewhat different conditions as the potential suburban business had spread out and extended farther from the London terminals. Other carriers, however, competed for the business, making electrification still desirable.

Finally, the latest reason for electrification of the Southern's remaining steam suburban service is that the steam trains make it impossible to work the electric suburban service to full advantage of its possible speed and capacity. This has resulted in plans for elimination of all steam suburban service and substitution of multiple-unit trains.

Other changes had to be made in order to secure the greatest improvement from the faster acceleration and quicker turn-about of the electric trains. The terminals have been rearranged, certain lines rerouted to prevent part of the cross traffic, and new switching and signalling installed in the terminal zones.

As the situation stands today, the Southern has apparently won back the lost patronage, added much new business, and is now building up its territory with a permanent riding public. The railway's analyses of its traffic indicate the futility of attempting to attract patronage within a certain radius of city terminals, say about 4 miles. Ability to run the inner 4 miles at high speed, without stops, makes the service more attractive to the residents beyond. This company expects that the greatest development of electrification in succeeding years will take place between the 4-mile and 30-mile circles, as it has found that, by pushing out farther into the country with suburban electrified lines, it is able to stimulate an increase of new business on the new sections, considerably over-balancing the loss of riders in the close-in districts and making a definite gain in the total suburban business handled.

The first experience with electric motive power by the railways constituting the present Southern

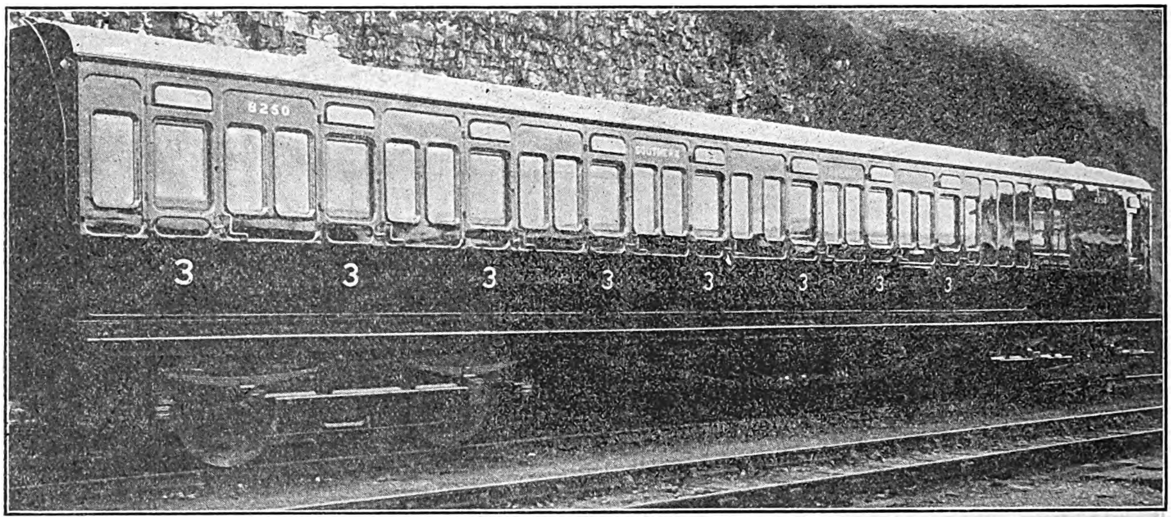

FIG. 7—SOUTHERN RAILWAY—THIRD CLASS COACH FOR LONDON SUBURBAN SERVICE.

Railway system dates back to 1898 when a short tube was built in the heart of London.

Several years later, in 1909, the London, Brighton & South Coast Railway opened the first section of a single-phase electrification using 6600 volts and 25 cycles. This was later extended several times and is now the central section of the Southern's suburban lines.

Alternating current was adopted for this service on account of the long distance to which it was intended to carry the electrification, and the possibility of extending it to the main through service of the company. At the time of consolidation the alternating-current system had grown to 24 route miles. With work then in progress, it reached its culmination in 1925 with a total of 41 route miles. All of the alternating-current lines will eventually be changed to direct current, as explained later.

Prior to the War the London and South Western Railway had started to electrify some of its service. The work was brought to completion in 1915 and 1916 on 49 route miles, and is now embraced in the western section of the Southern's suburban lines. It utilizes a third rail energized with direct current at 650 volts. At the time of consolidation the railway was committed to extend on 30 route miles. With further additions there are now 89 miles of route and 250 miles of track electrified in this western section.

The London & South Eastern Railway which now forms the eastern section of the consolidated lines had considered electrification for several years before the War but did not get started. Afterwards it completed plans for 100 route miles, but construction was not begun until after the consolidation of 1923. This section uses 650-volt direct current supplied by a third rail, like the western section.

Electrification of the eastern section was first brought into service in 1925 and continued in subsequent years. At the end of 1928, with some mileage converted from alternating current on the old Brighton lines, there is a total of 175 miles of route and 489 miles of track electrified with direct current in the eastern and central sections.

As the work progressed it was found that the full advantages of consolidation would not be attained with 2 direct-current zones separated by the intervening alternating-current zone of the old Brighton railway. Hence it was decided to change the latter to the new company's standard third-rail system. Some of the mileage has been changed to direct current and a part has been paralleled with third rail so that both kinds of trains can operate. Ultimately all of the high-tension overhead will be removed.

Taking the 3 sections together there are, at the end of 1928, 264 route miles and 739 track miles using the third rail. The central section still contains 30 route miles and 108 track miles electrified with alternating current. This gives a total of 294 route miles and 847 track miles altogether in the 3 sections, which will be increased to 875 track miles in 1929 when work in process is completed.

Multiple-unit trains are used for all this service. There are at present 488 motor cars and 452 trailers, a total of 940 cars, on the direct-current lines. There are also 71 motor cars and 164 trailers on the alternating-current lines. All of this rolling stock, except about 10 per cent, has been provided by conversion of the former steam stock. This practice will be followed in the future as far as possible in order to retain serviceable equipment.

It is now customary, on replacing steam service, to schedule about twice as many trains per day. Other improvements, such as described above, in rearranging terminals, new signalling and elimination of steam suburban trains from terminal zones, have permitted 50 per cent increase in number of trains over the schedules provided in the earlier days of electric service.

Due to faster and more frequent service the patronage has shown a very gratifying response. Although the total number of passengers carried by all railroads in England showed a decrease of nearly 75,000,000 between 1925 and 1927, the Southern Railway registered an increase of more than 7,000,000 passenger rides in this period between the same stations in its electrified area. During January, 1928, the number of passenger rides increased nearly 700,000 over January, 1927, between stations in the electrified area. As an indication of the volume of traffic carried into and out of London by this railroad, a count in February, 1928, showed nearly 524,000 passengers on a normal day, handled at 6 terminals. The heaviest hours of morning and evening accounted for 75,000 passengers each.

Two districts of the Southern Railway electrification were visited, including a trip to the steam power station at Wimbledon Park, which supplies energy for the western section. This station, adjacent to the car shops at Wimbledon, has a capacity of 25,000 kw. for 3-phase energy at 25 cycles. The power is transmitted at generator pressure of 11,000 volts to the converter stations which feed into the third rail at 650 volts.

Energy is purchased for the eastern section, also third rail, and there are altogether 49 direct-current substations. Energy is also purchased for the present alternating-current electrification in the central section.

Future Plans

It is difficult to say just what may be done about electrification. The railroads were consolidated for economy of working. Since that time, however, there have been 2 negative influences which have delayed the anticipated results and retarded development: (1) depression of the coal industry with consequent decrease of coal traffic, and, (2) large increase in road-vehicle competition for both passenger and freight business.

Due to the insularity of the country and its numerous rivers, there is no part very far from ocean transportation, which serves to move a large tonnage of heavy and slow-moving goods. At the present time much of the lighter and short-haul traffic is handled by highway carriers. These facts, together with the considerable investment required for electrification, have tended to prevent its development—except for suburban service. However, the railway electrification committees above cited have made a considerable study of the technical requirements which would be imposed by trunk-line electrification. Their recommendations are intended to embrace the best choice of system for economy, interchange of equipment, and proper clearances with the most economical use of existing structures.

There is a new development in England which may have some effect on this matter of electrifying trunk lines. That is the new extensive grid system, or transmission network, for supplying large quantities of electric power from large, efficient steam power stations. This system is being planned and carried to conclusion by a board acting under authority of the Government. The grid system aims to cure the previous lack of harmony and efficiency of power supply from many small plants of diverse frequencies. Having abundant coal resources within its own confines, there is no present indication that England will be impelled to electrify its railways as a measure of national economy like some of the other European countries. Whether the unification of electricity supply, however, will bring any important results or economies that will have a bearing on trunk-line electrification cannot be predicted.

As for suburban service, the traffic around the large cities is very heavy. Two railroads at London have considerable suburban service electrified, and state that their electric operations are very satisfactory. Other railways in the North are giving suburban service with electric trains that they say would be difficult to render with steam. The opinion of railway men interviewed in England seems to be that suburban electrification will extend gradually in the future as it has in the past.

The Netherlands

Netherlands Railways

The Netherlands Railways are operated by a corporation in which the National Government is a large shareholder. About 81 miles of line have been electrified in the district between Amsterdam and Rotterdam. Multiple-unit trains are used for local and express passenger service. International trains and freight trains are still operated over the same tracks by steam locomotives.

Electrical operation was adopted because traffic between Amsterdam and Rotterdam was so congested that more capacity had to be provided. The

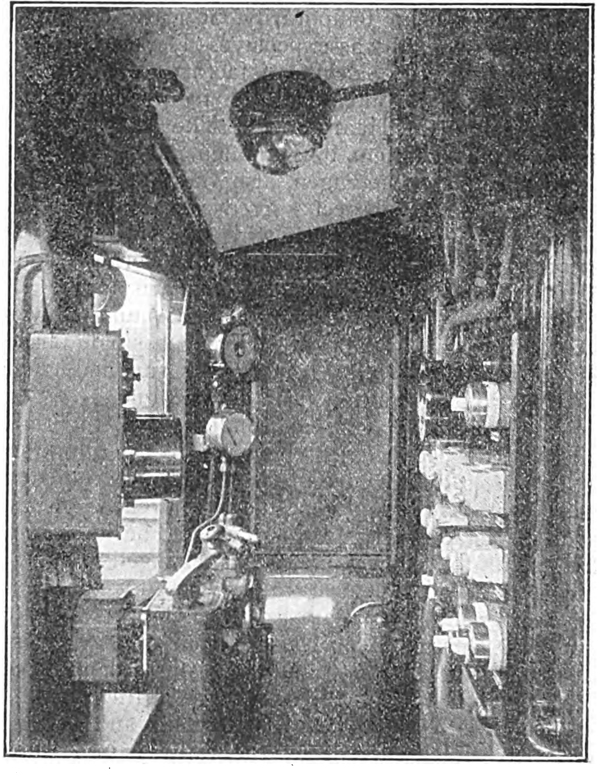

FIG. 8—NETHERLANDS RAILWAYS—DRIVER'S CAB ON ELECTRIC MOTOR CAR.

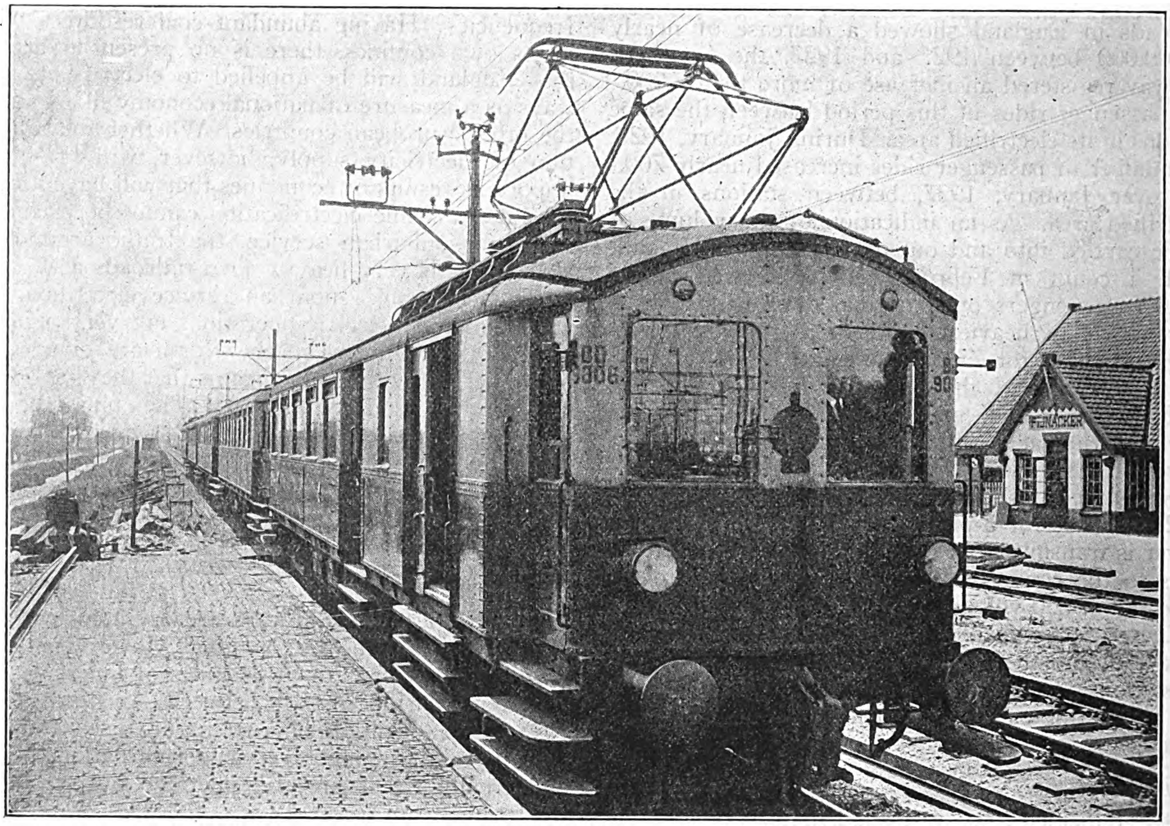

FIG. 9—NETHERLANDS RAILWAYS—MULTIPLE-UNIT TRAIN.

main line was double-track, and it was necessary to electrify or to add 2 more tracks. Electrification solved the problem temporarily, at least, during a period when capital was expensive. The electric service is reported to be very satisfactory.

The electrified routes are (1) from Amsterdam to Rotterdam via Haarlem and The Hague, with branch from Haarlem to Ijmuiden, and (2) from Rotterdam to Scheveningen, also via The Hague by a different route. Direct current at 1500 volts is supplied by a double contact wire suspended from a catenary. Several different types of overhead construction have been installed for comparison.

The line from Rotterdam to Scheveningen was built for electric traction in 1908 using single-phase current at 10,000 volts. Energy was supplied from a separate power station near The Hague.

Since 1920 investigations conducted by the railways and the Government have led to the adoption of 1500-volt direct current as a national standard for railways. It was also decided to purchase energy from the established power systems. The line from Rotterdam to Scheveningen was changed to 1500 volts in 1926, and electric trains were introduced on the Amsterdam-Rotterdam line in 1927.

Electric energy is purchased from 3 power systems operating in the vicinity of Amsterdam, Rotterdam and The Hague. This energy is furnished as 3-phase at either 6000 or 10,000 volts, and is converted to direct current by the railway in 7 substations. Three or 4 mercury arc rectifiers are installed in each substation, except at The Hague where there are 2 rectifiers and 2 motor-generator sets.

The substation visited at Amsterdam contains 3 rectifier sets, each composed of 2 bowls. Ordinarily 2 sets are used and one held in reserve. The capacity of each set is 1000 kw. continuous, and 1500 kw. for two hours. There is one transformer for each set. The rectifiers and all switching operations of the substation are actuated by remote control from a nearby switch tower. Little trouble has been experienced with flash-backs, interruptions lasting not more than 2 or 3 minutes.

Trains are composed of motor and trailer cars in like numbers. The motor cars are equipped with four 180-horsepower motors, connected two in series across 1500 volts. They also have electro-pneumatic control and air brakes. The electrical equipment is all hung underneath the body, and not placed in the car, as seen in several European countries. Current is collected by pantographs. Car heating is done by electricity at the voltage of the contact line. Lighting current is furnished by a special generator and storage battery. The control circuits have the same voltage as the lighting. Acceleration is automatic and the full speed of 59 m.p.h. is attained in 3 minutes.

The motor cars weigh about 68 tons and the trailer cars about 44 tons. The bodies are steel and trucks are 4-wheel of M.C.B. type. Cars have end entrances and center aisles, with one or two cross

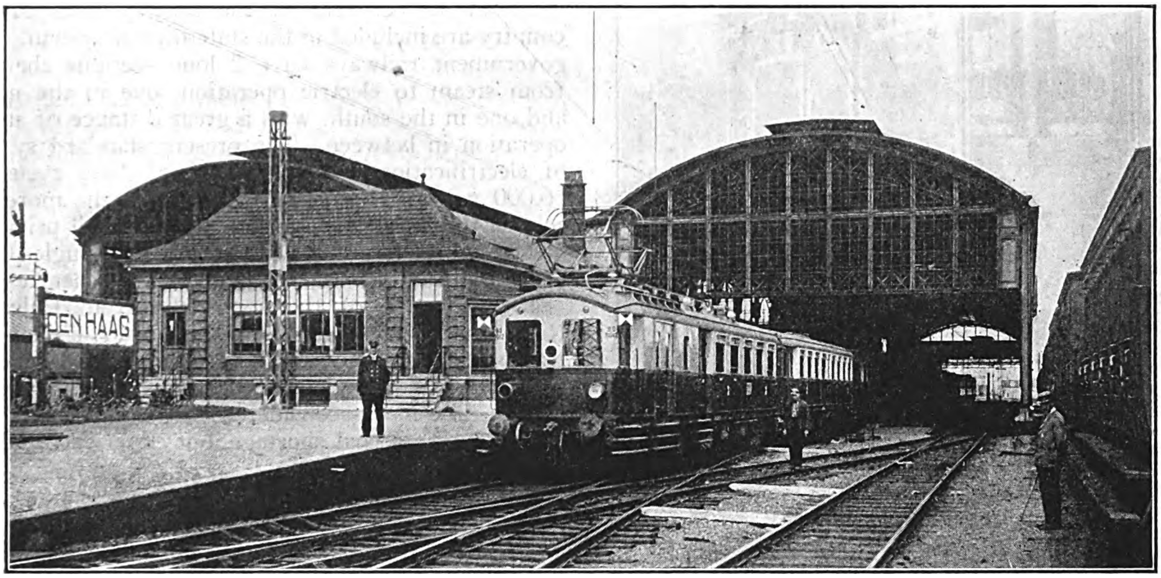

FIG. 10—NETHERLANDS RAILWAYS—ELECTRIC TRAIN AT THE HAGUE.

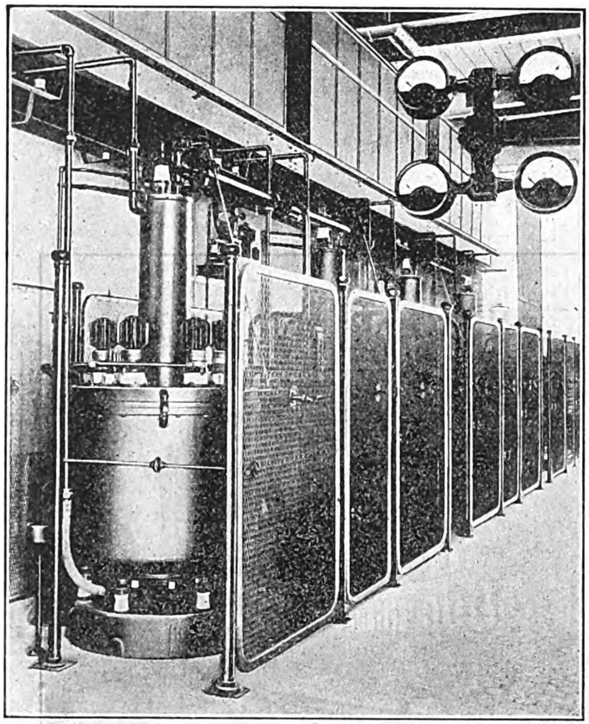

FIG. 12 — NETHERLANDS RAILWAYS — RECTIFIERS IN SCHIEBROECK SUBSTATION.

partitions making separation of the smoking and non-smoking sections. Second and third class cars are used. A trip was made over the line on an express train from Rotterdam to Amsterdam and return. The cars ride well and the service is quite commendable.

Future plans contemplate: (1) purchase of electric locomotives for hauling long-distance passenger trains and freight trains over the present electrified sections; (2) addition of more tracks to the main line between Amsterdam and Rotterdam to care for the increase of business since electric traction was installed; and, (3) the extension of electrification to other lines of which Amsterdam-Utrecht will probably be the first.

Sweden

Swedish State Railways

About 40 per cent of the railway lines of the country are included in the state-owned system. The government railways have 2 long sections changed from steam to electric operation, one in the north and one in the south, with a great distance of steam operation in between. The present standard system of electrification is single phase of 16⅔ cycles at 16,000 volts. This system is used on the more recent of the 2 electrifications. Several small privately owned railroads are electrified, all with single-phase energy but of different voltages and frequencies.

Electrification of the north line from Luleå to Riksgrensen was started before the War, largely for traffic reasons. The primary cause for further electrification has been developed by the War. Previous to that time it was considered that wood fuel would suffice during a coal shortage, but experience proved otherwise.

The preventive for such occurrences is now considered to lie in linking up the railways with the already well-developed State Power System, which has an abundant supply of water power. It was thus decided to electrify some of the important lines, of which the Stockholm-Gothenburg line should be the first on account of its having the greatest coal consumption per mile of route.

The single-phase system was chosen with the same line voltage as the earlier electrification, namely 16,000, but using 16⅔ cycles to facilitate conversion from the 50-cycle power system, while the older electrification uses 15 cycles from independent gen-

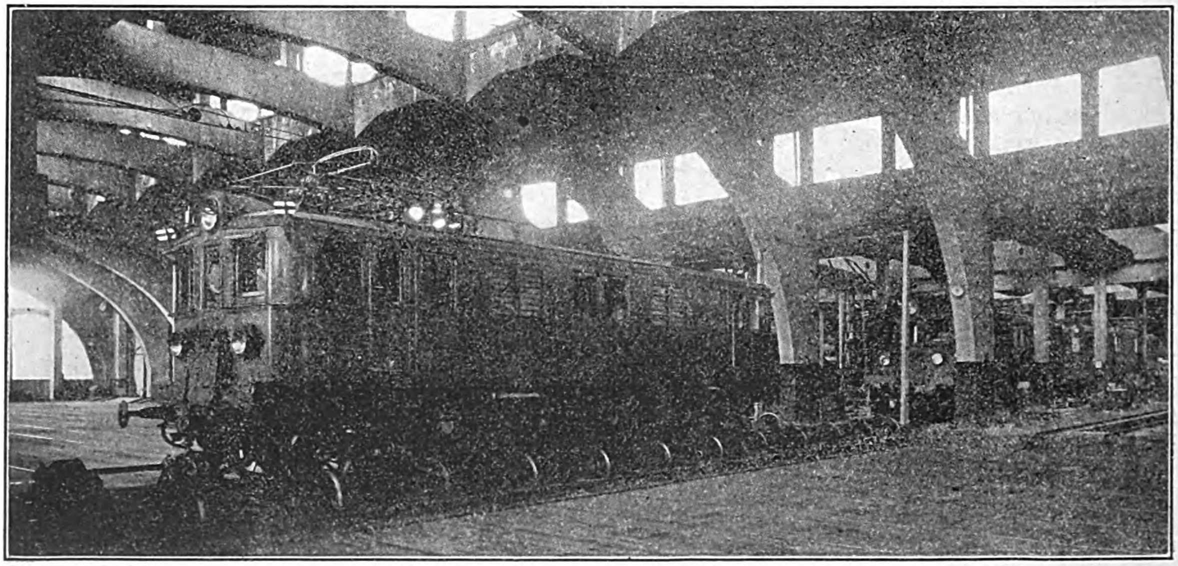

FIG. 13—SWEDISH STATE RAILWAYS—LOCOMOTIVE IN INSPECTION SHOP AT STOCKHOLM.

erators. This slight difference in frequency will not prevent exchange of locomotives between the two lines, although this is unlikely at present as they are several hundred miles apart.

Lulea-Riksgrensen Electrification

The first electrification of the State Railways was on the ore railroad in the northern part of the country. The line extends from Lulea on the Gulf of Bothnia to Riksgrensen on the Norwegian frontier. From here it continues as part of the Norwegian State Railways to the port of Narvik on the Atlantic Coast of Norway. Most of this line is above the Arctic Circle, and it was too far off the itinerary to be visited. Considerable information was secured, which will be briefly stated here.

This line serves the iron mining districts of Kiruna and Gallivare in Northern Sweden. Large tonnages of ore are shipped in both directions to the ports of Lulea and Narvik. Heavy tonnage traffic and availability of water power dictated electrification. The first electrified part went into operation in 1915 and was gradually extended until complete electric operation was accomplished in 1922.

Power is furnished from the northern detached section of the Swedish State Power System. There is one hydraulic generating station at Porjus which supplies power for the mining district and for many communities. The head is about 184 ft. This plant, built in 1914, now contains 3 generators for power and 4 for railway purposes. The power generators are each 11,000-kw., 3-phase and 25-cycle. The railway generators are each 8500-kw., single-phase and 15-cycle.

The railway energy is transmitted to and along the railway right-of-way at 80,000 volts. There are 13 transformer stations feeding the contact line with 16,000 volts. The average distance between transformer stations is 21.8 miles.

The original freight locomotives were of the type 1 C + C 1, weighing 152 tons. The passenger locomotives were 2 B 2, weighing 90 tons. Since then several different types of locomotives have been purchased for this line, mostly freight locomotives as only a small amount of passenger equipment is required.

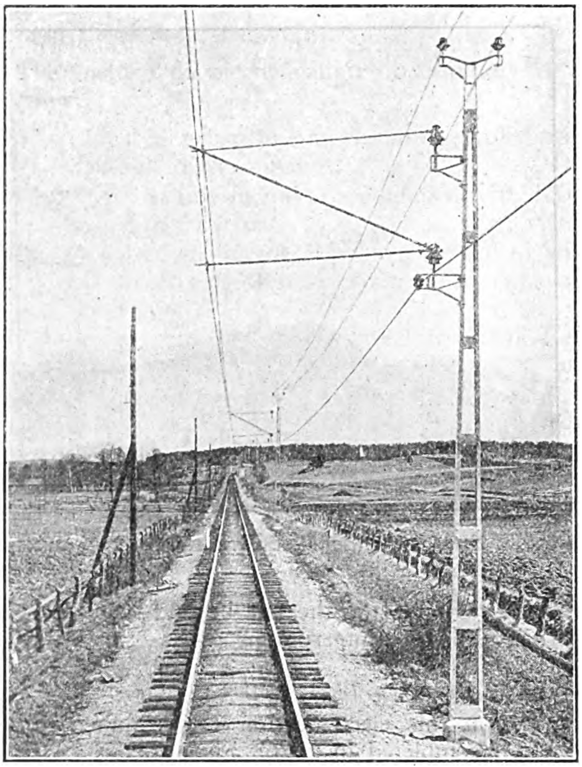

FIG. 14—SWEDISH STATE RAILWAYS—CONTACT LINE ON STOCKHOLM-GOTHENBURG ELECTRIFICATION.

The latest freight locomotives for this line are type 1 C + C 1, weighing 141 tons. They have 2 cabs with one large motor in each. The motor drives by connecting-rods to a jack-shaft from which side-rods link together the 3 driving axles. The speed is 37.3 m.p.h. The maximum train weight is 2095 tons per locomotive.

The Norwegian State Railways provide locomo-

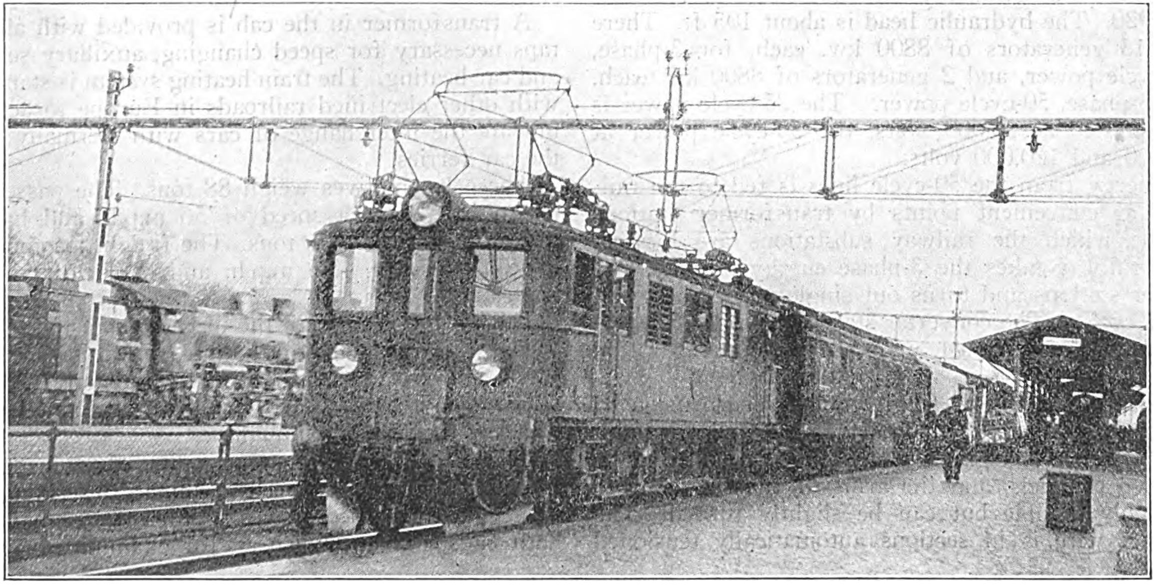

FIG. 15—SWEDISH STATE RAILWAYS—TRAIN AT HALLSBERG ON STOCKHOLM-GOTHENBURG LINE.

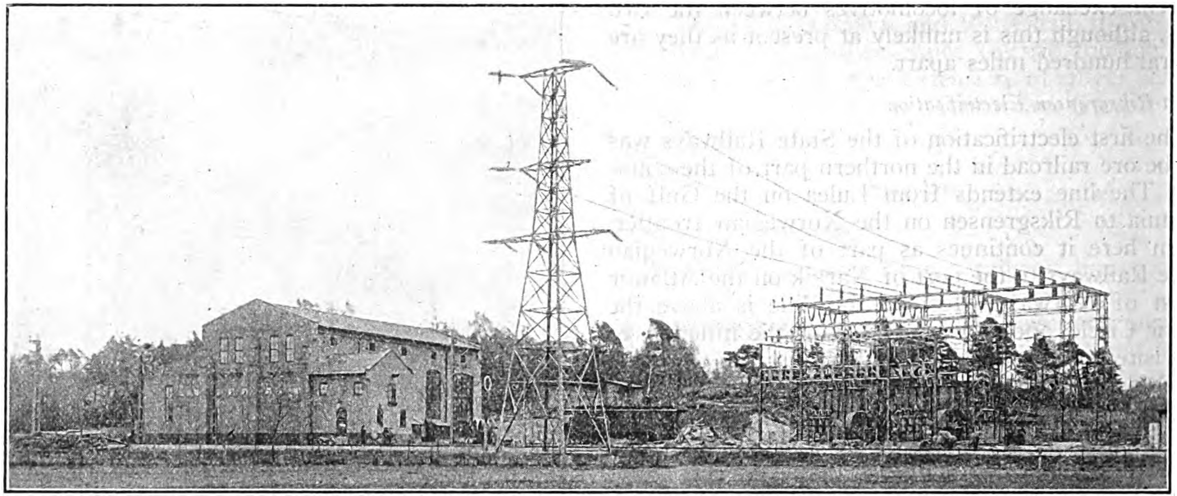

FIG. 16—SWEDISH STATE RAILWAYS—ALINGSAS CONVERTER STATION ON STOCKHOLM-GOTHENBURG ELECTRIFICATION.

tives for their end of the line beyond Riksgrensen. There is also some interrunning.

Stockholm-Gothenburg Electrification

Work on this electrification was commenced in 1923 and completed in 1926. Since Oct. 1 of that year the operation has been electric for all trains over the whole line.

Energy for this new electrification is supplied from an interconnected network of the State Power System which covers the whole district through which the railroad line extends. The network is fed by one steam station and 4 hydraulic generating stations. Two of the hydroelectric stations were visited—Motala and Trollhattan.

The Motala power station, in service since 1922, has a head of about 49 ft. The present installation consists of two 4800-kw. generators for 3-phase, 50-cycle power. Transmission is at 70,000 volts.

The Trollhattan power station is the largest in the State Power System. It commenced operation in 1910 and was gradually extended to its present size in 1920. The hydraulic head is about 105 ft. There are 13 generators of 8800 kw. each, for 3-phase, 25-cycle power, and 2 generators of 8800 kw. each, for 3-phase, 50-cycle power. The 25-cycle power is transmitted at 50,000 volts, the 50-cycle power at 50,000 and 120,000 volts.

Energy from the 50-cycle lines is fed to the railway at convenient points by transformer stations beside which the railway substations are located. The railway takes the 3-phase energy into its converter stations and turns out single-phase energy at 16⅔ cycles. The converter stations number 5, averaging 58.5 miles apart, with a maximum separation of 80 miles.

The contact line is single catenary suspension of Z-type construction which had been well tried out on the Lulea-Riksgrensen line. The poles are made of two channels, and the arms of tubes which are not only flexible but can be slightly turned. The contact wire is in sections automatically tensioned at each end by counterweighting devices attached to the supporting poles.

It is not necessary to use an auxiliary feeder in addition to the contact wire. There is a return wire carried on the supporting poles. This wire takes current from the rails at frequent intervals through booster transformers. The rails are not bonded.

A great deal of experimenting was done on the Lulea-Riksgrensen line with regard to communication circuits. The return feed wire was, as a result, applied to the new electrification, and the communication circuits cabled underground. It is said that the results are quite satisfactory.

The locomotives of this line are alike for passenger and freight trains, excepting the gear ratio. They are all of the same design, made by 3 locomotive factories from identical drawings. They are of the type 1 C 1. The single cab contains a twin motor of 1700 horsepower with the 2 halves electrically connected in series. The armatures are geared to a jack-shaft which connects to the 3 driving axles by side-rods.

A transformer in the cab is provided with all the taps necessary for speed changing, auxiliary service and car heating. The train heating system is standard with other electrified railroads in Europe to accommodate the interchange of cars with Germany over the car ferries.

These locomotives weigh 88 tons. The passenger locomotives have a speed of 56 m.p.h. and haul a maximum train of 550 tons. The freight locomotives have a speed of 43.5 m.p.h. and haul a maximum train of 990 tons.

During the year 1927 the maximum distance covered by any passenger locomotive of this type was 101,300 miles, and by any freight locomotive 58,900 miles. The average yearly mileage was about 15 per cent less than the maximum.

The Stockholm-Gothenburg line was inspected most of the way between terminals by riding on passenger-train locomotives. Stops were made at both ends and at Hallsberg for examining various special features. Side trips were made from Hallsberg to Motala and Orebro, and from Gothenburg to Trollhattan. These side trips covered locomotive factories, hydroelectric stations, and the main locomotive shop at Orebro.

This electrification seems to be very satisfactory, and the comparative statistics of train operation and traffic show a great improvement over steam operation. Since the installation of electric motive power the running time has been very much reduced for both freight and passenger trains. Congestion has been eliminated and the capacity of the line greatly increased. As a result, the passenger service has been augmented by many more trains which seem to be appreciated by the railroad's patrons.

General and Future

Since 1926, the Swedish State Railways have 570 miles of line operated by electricity. This is 17.5 per cent of the line, but the traffic involved is not less than 25 per cent of the total train-miles. There are 109 electric locomotives and 2 electric motor cars.

Future plans call for extension of electric traction on the lines of heavy traffic. The lines under consideration at present are Stockholm-Malmo, Gothenburg-Malmo, and Stockholm-Upsala. A definite announcement of the undertaking of some of this work will probably be made soon.

Germany

Germany stands third among the countries of Europe in respect to miles of railroad electrified. Switzerland and Italy are the only countries that have electrified more miles of line. Since all the main-line railways of the country are embraced in one organization under control of the National Government it is only necessary to describe the electrical operations of this one company.

German Government Railways

The history of electrification in Germany is as follows:

1903—Short suburban line at Berlin electrified with 550-volt direct current.
1908-09—Short line in Bavaria equipped with 1000-volt direct current.
1908—A suburban line at Hamburg electrified with 6000-volt single-phase power. This was extended in 1924.
1910—An experimental line installed in Middle Germany for test of high-voltage alternating current.
1911—Hamburg Harbor line electrified with 3000-volt single-phase power.
1912-13—Mittenwald Railway between Garmisch and Innsbruck (Austria) built for initial operation by electric power.
1913—A few miles of high-voltage single-phase electrification installed in the southern part of Baden.
1914—The first Silesian line equipped for high-voltage single-phase operation. Gradual extensions of this installation have been made up to the year 1928.
1916—First Bavarian electrification in operation with high-voltage single-phase power. Other Bavarian lines electrified in 1925 and each year to 1928.
1916—Small narrow-gage line electrified in Saxony.
1922—First section of high-voltage single-phase electrification in Middle Germany completed. It was extended in 1923-25-27.
1924—Berlin suburban electrification first began to operate (with third rail). Added to gradually ever since and nearly completed at end of 1928.

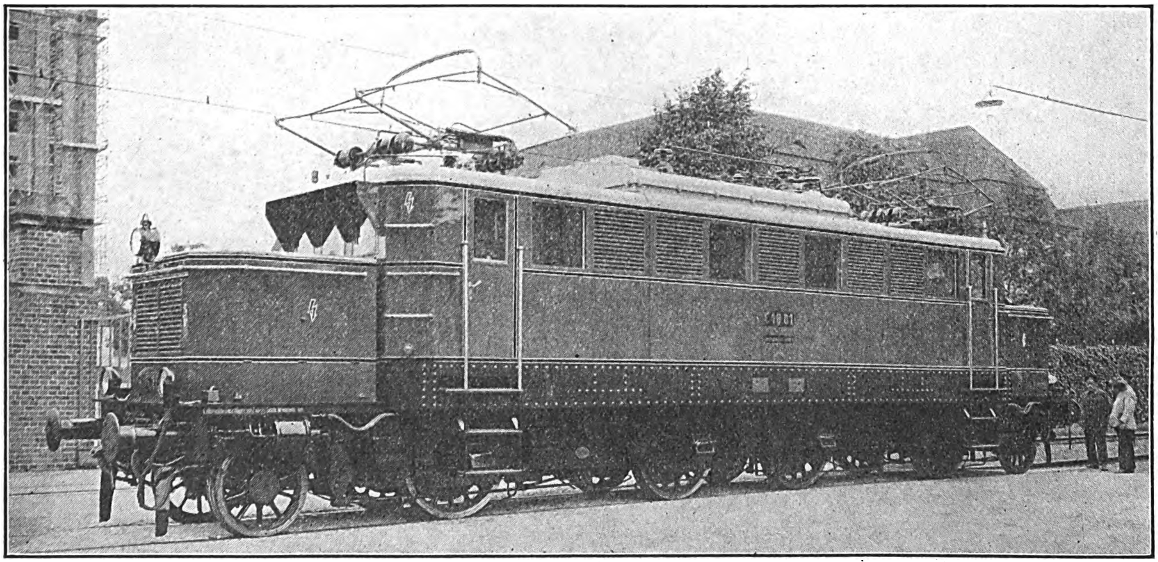

FIG. 17—GERMAN GOVERNMENT RAILWAYS—BAVARIAN DISTRICT—HIGH-SPEED LOCOMOTIVE WITH INDIVIDUAL-AXLE DRIVE.

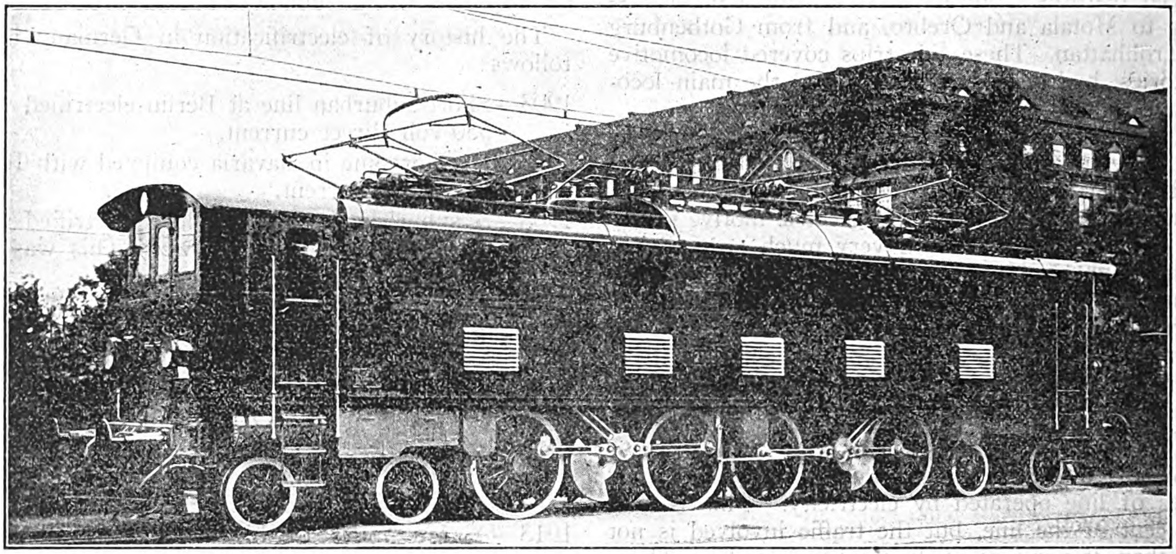

FIG. 18—GERMAN GOVERNMENT RAILWAYS—BAVARIAN DISTRICT—PASSENGER LOCOMOTIVE WITH SIDE-ROD DRIVE.

In 1910, as stated above, an experimental line was equipped in Middle Germany for train operation with alternating current. The progress of main-line electrification starts from this time. Plans were made shortly thereafter for electrification of considerable mileage in widely separated districts, on the flat lines of Middle Germany and on the mountain lines of Silesia, also in Bavaria. Only a small mileage, in the last 2 districts, had been electrified when the War caused almost complete cessation of activity. The work, when resumed after hostilities, began to show its effects about 1922, and since then there has been a steady increase in electric operation.

The following figures show the extent of electrification at the end of the last 3 years, and the per cent of the whole system electrified:

	Route Miles	Per Cent of System
1926	625	1.9
1927	757	2.3
1928	963	2.9

The German Government Railways now have 4 principal zones of electrification. Arranged in order of size, according to the route miles, they are:

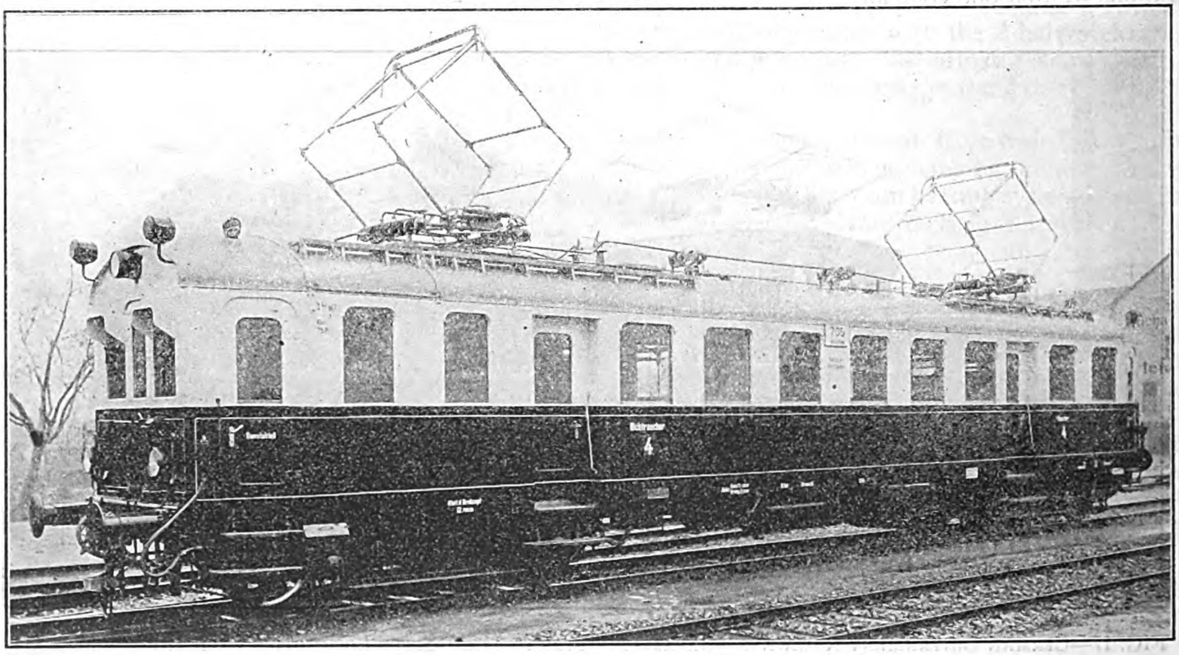

FIG. 19—GERMAN GOVERNMENT RAILWAYS—BAVARIAN DISTRICT—MOTOR CAR FOR 15,000-VOLT LINES.

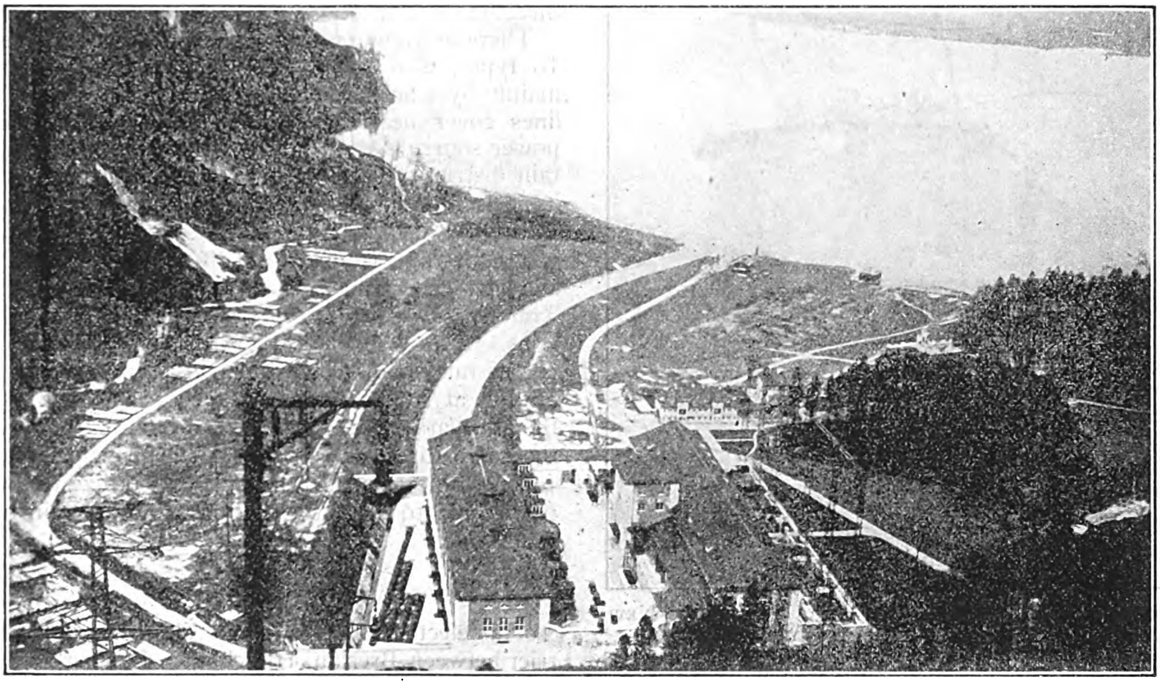

FIG. 20—BAVARIAN POWER COMPANY—WALCHENSEE HYDRO-ELECTRIC POWER STATION.

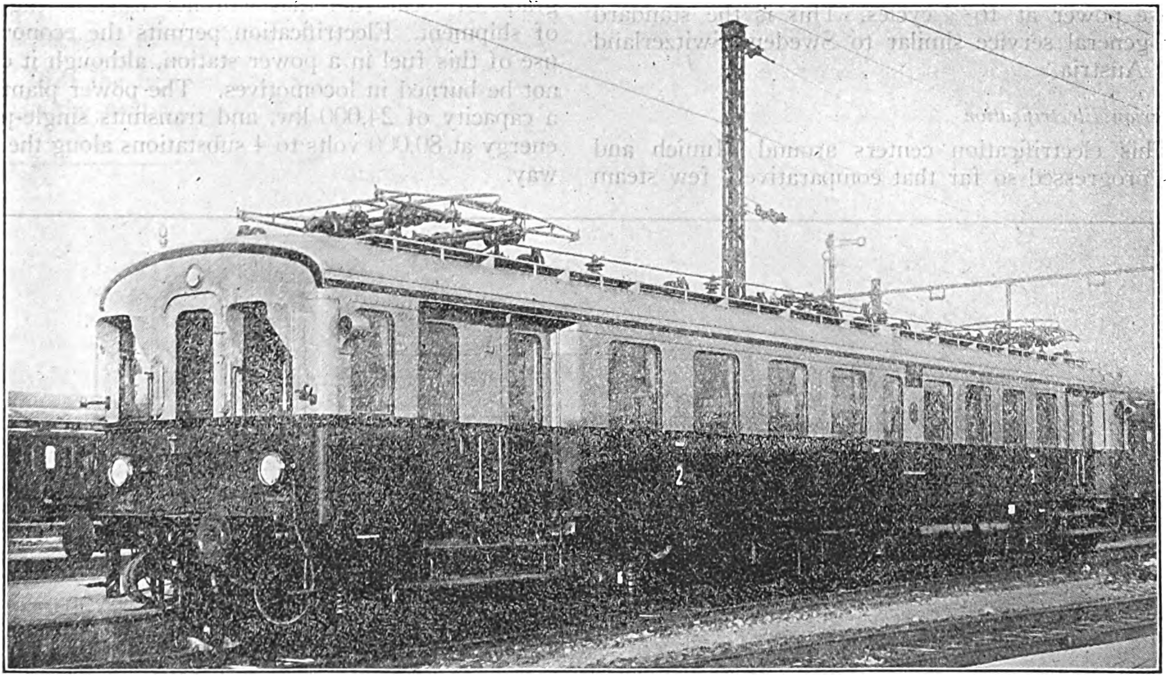

FIG. 21—GERMAN GOVERNMENT RAILWAYS—HALLE DISTRICT—MOTOR CAR FOR 15,000-VOLT LINES.

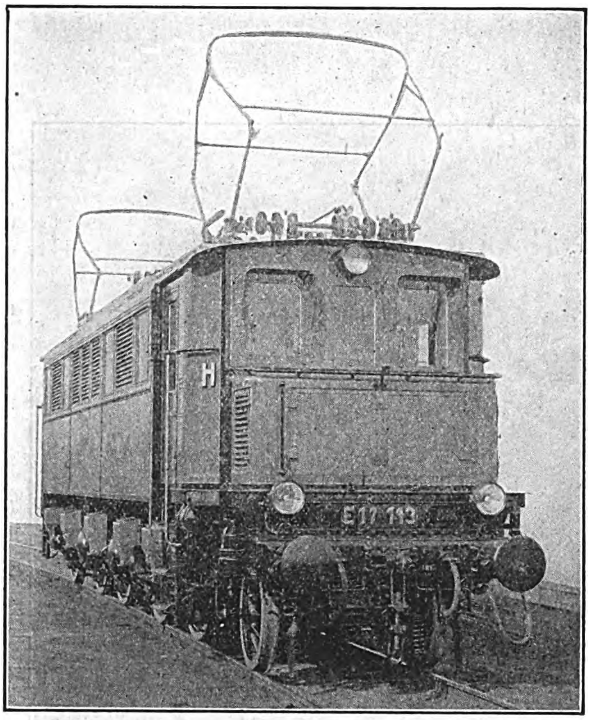

FIG. 22—GERMAN GOVERNMENT RAILWAYS—NEW STANDARD PASSENGER LOCOMOTIVE, FRONT VIEW.

	Route Miles
Bavaria	434
Silesia	215
Berlin (Suburban)	145
Middle Germany	114

Excepting the Berlin suburban lines, these important zones are energized with 15,000-volt single-phase power at 16⅔ cycles. This is the standard for general service similar to Sweden, Switzerland and Austria.

Bavarian Electrification

This electrification centers around Munich and has progressed so far that comparatively few steam locomotives are seen in that vicinity. Electric operation extends to Regensburg on the north and into Austria in 4 places on the south. About 434 miles are electrified, including the 11 miles electrified with direct current in 1908.

There are now on this division 196 locomotives of 16 types, also 40 motor cars. Power is supplied mainly by a large hydroelectric power system whose lines cover nearly the whole state. The principal power source is the Walchensee station in the mountain district south of Munich. As the power system itself is three-phase, the railways have arranged for the power company to install separate single-phase generators and transmission lines. There is 80,000 kw. of generating capacity for railway service. Transmission is at 110,000 volts to 6 railway substations.

The railway also owns 2 small power stations generating at trolley voltage. One of 5000 kw. is for the alternating-current lines and one of 600 kw. for the small direct-current line. The principal reasons for electrification in Bavaria are to utilize the water power and to increase the capacity of certain heavy grade lines.

Silesian Electrification

This electrification is in the Silesian mountain district between Breslau, Hirschburg, Lauban and Gorlitz. About 215 miles are involved. Grades are heavy and traffic considerable. There are 92 locomotives of 10 types and 21 motor cars. Power is supplied by the railway's own power station at Mittelsteine in the southern part of Silesia.

Aside from reasons of traffic, another important reason for this electrification is to utilize a very low grade of local fuel that will not warrant the cost of shipment. Electrification permits the economical use of this fuel in a power station, although it could not be burned in locomotives. The power plant has a capacity of 24,000 kw. and transmits single-phase energy at 80,000 volts to 4 substations along the railway.

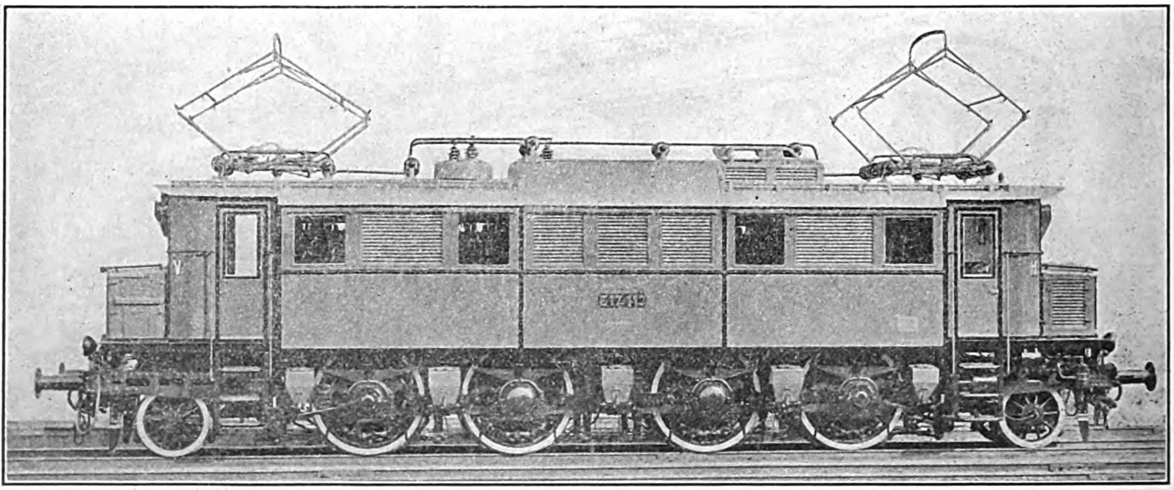

FIG. 23—GERMAN GOVERNMENT RAILWAYS—NEW STANDARD PASSENGER LOCOMOTIVE, SIDE VIEW.

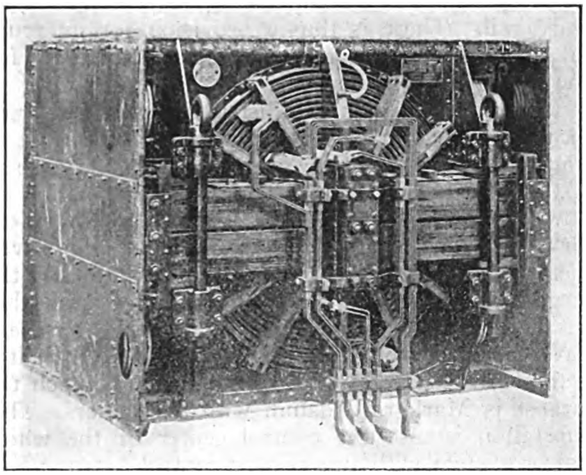

FIG. 24—GERMAN GOVERNMENT RAILWAYS—NEW STANDARD PASSENGER LOCOMOTIVE, AIR-COOLED TRANSFORMER.

Electrification in Middle Germany

This electrification covers a territory extending from Magdeburg to Leipzig and Halle, and the lines total 114 miles. It was undertaken particularly for the purpose of utilizing the local deposits of brown coal. This is of the nature of peat, very low in combustible and containing more than 50 per cent of moisture. It must be consumed on the spot as it will not bear any cost of transportation, neither is it suitable for locomotive fuel.

The railway has erected near Bitterfeld a steam power station of 26,500 kw. The single-phase power is transmitted at 60,000 volts to 3 substations. Traction is furnished by 104 locomotives of 11 types and by 5 motor cars.

Berlin Suburban Electrification

In 1924 the first electrical operation of suburban lines in the vicinity of Berlin was introduced. The whole task of converting the suburban service from steam to electricity comprises 145 miles of the so-called City, Ring and Suburban Railway. This work was nearly completed at the time of the Subcommittee's visit. The motive power consists of 481 motor cars which are being progressively equipped in a large, modern and well-equipped overhaul shop which the railway has built at Nieder Schoneweide on the outskirts of Berlin.

The reason for this electrification was the necessity for the improved handling of the suburban service in the congested districts at the center of the city. This called for more traffic capacity which is being given by the faster movement and more rapid

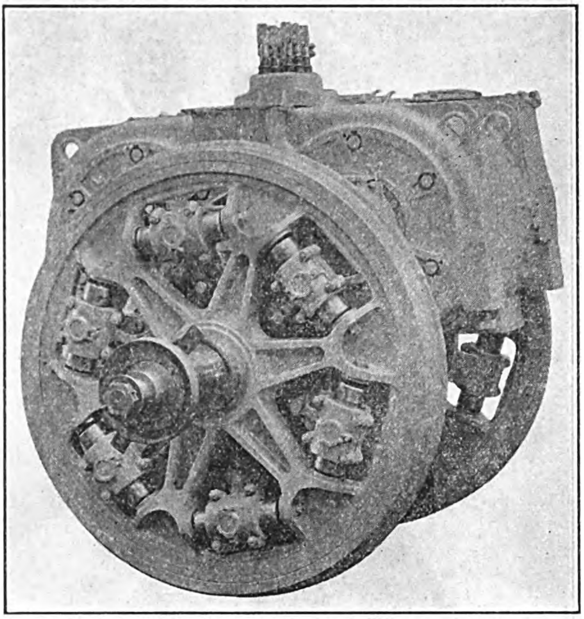

FIG. 25—GERMAN GOVERNMENT RAILWAYS—NEW STANDARD PASSENGER LOCOMOTIVE, TWIN MOTOR AND AXLE ASSEMBLY.

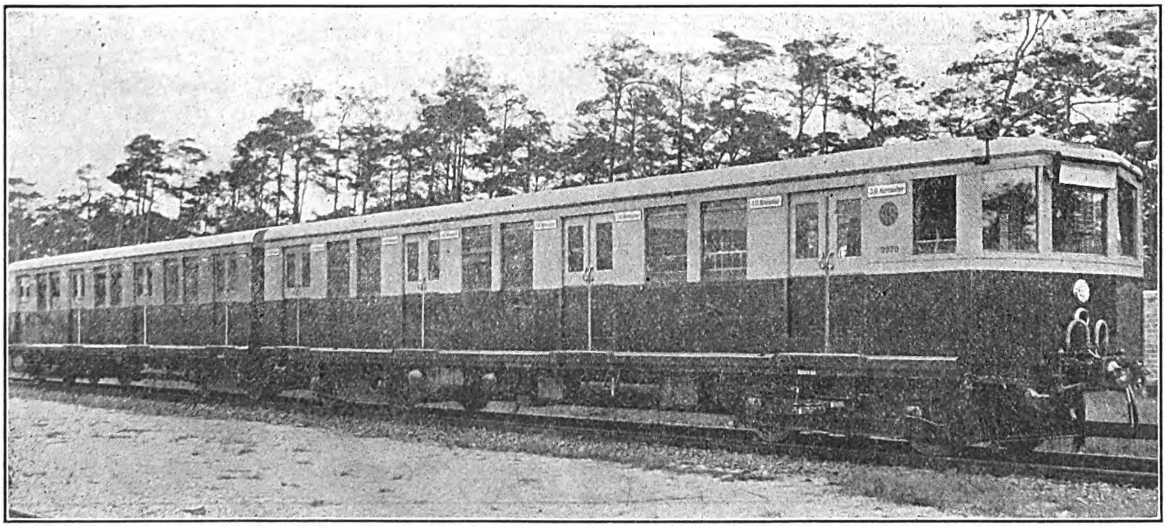

FIG. 26—GERMAN GOVERNMENT RAILWAYS, BERLIN DISTRICT—NEW SUBURBAN CARS FOR THIRD-RAIL OPERATION.

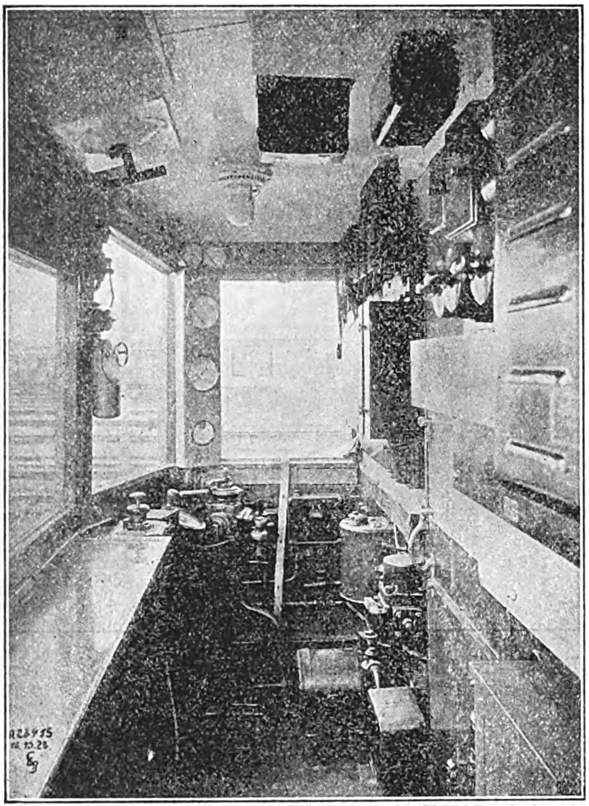

FIG. 27—GERMAN GOVERNMENT RAILWAYS—BERLIN DISTRICT—DRIVER'S CAB ON MOTOR CAR FOR NEW SUBURBAN SERVICE.

acceleration of multiple-unit trains. Direct current with third rail was selected as most suitable for this class of service. A comparatively high voltage was desired, and the pressure of 800 volts was adopted because the Berlin Elevated and Underground Railways system was already using this voltage on its third rail. There is thus a provision for interrunning between the two railways in the future, and for the use of joint substations.

Power for the suburban district is purchased from local power companies generating by steam. It is transmitted to the railway's substations as 3-phase at 30,000 and 110,000 volts. The whole installation of power, cars, shops and substations shows every effort to embody the latest and most improved methods. The conversion equipment is probably the largest aggregation of mercury arc rectifiers that has been installed anywhere. Most of the rectifiers have a capacity of 1200 kw. each. There are altogether 119 rectifiers in 48 substations, of which the largest is Markgrafendamm with 8 rectifiers. This substation is also the control center of the whole power system with supervisory control extending to the others.

Smaller Electrifications

In the state of Baden there are about 30 miles electrified between Basle, Zell and Sackingen. This is also 15,000-volt and single-phase, but the frequency is 15 cycles. There are 16 locomotives of two types. Power is purchased from a water power station at 6800 volts and 50 cycles. This is converted by the railway in a substation of 4000 kw. capacity.

In the Hamburg district there is a suburban line about 20 miles long operated with 25-cycle single-phase power. The overhead contact line is energized at 6000 volts. Motive power is furnished by 150 motor cars. This is an early installation and the rolling stock is all compartment type with side doors for each compartment. There is also a line to the Hamburg Harbor about 2 miles in length. This uses 3 locomotives with the same frequency but at 3000 volts. The railway company operates a steam power station with 28,500 kw. installed. Generation is

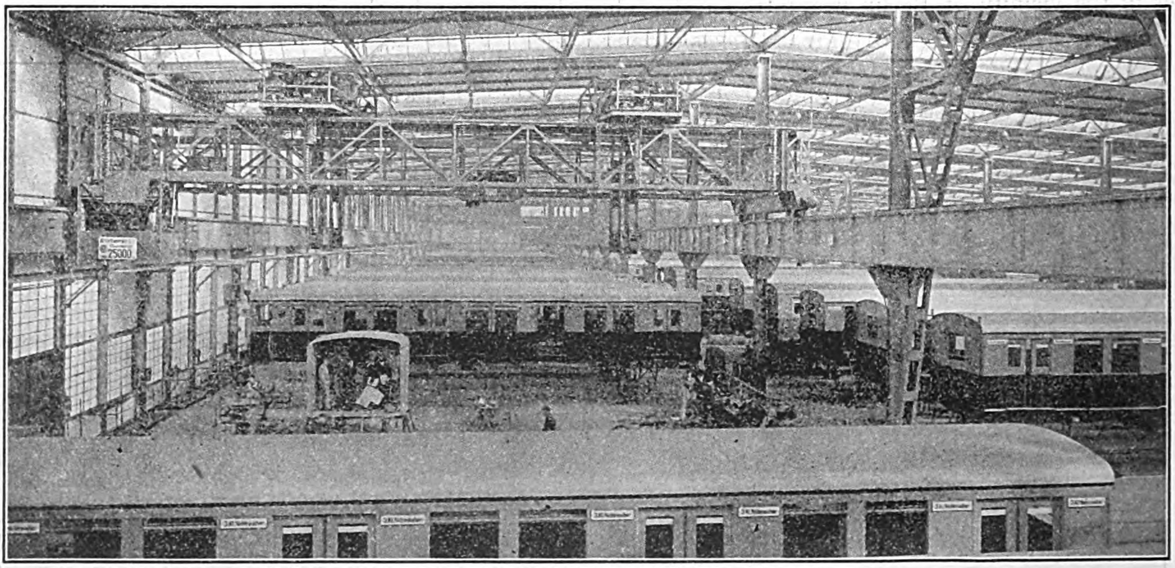

FIG. 28—GERMAN GOVERNMENT RAILWAYS—BERLIN DISTRICT—NEW SHOP FOR SUBURBAN CARS, BODY DEPARTMENT.

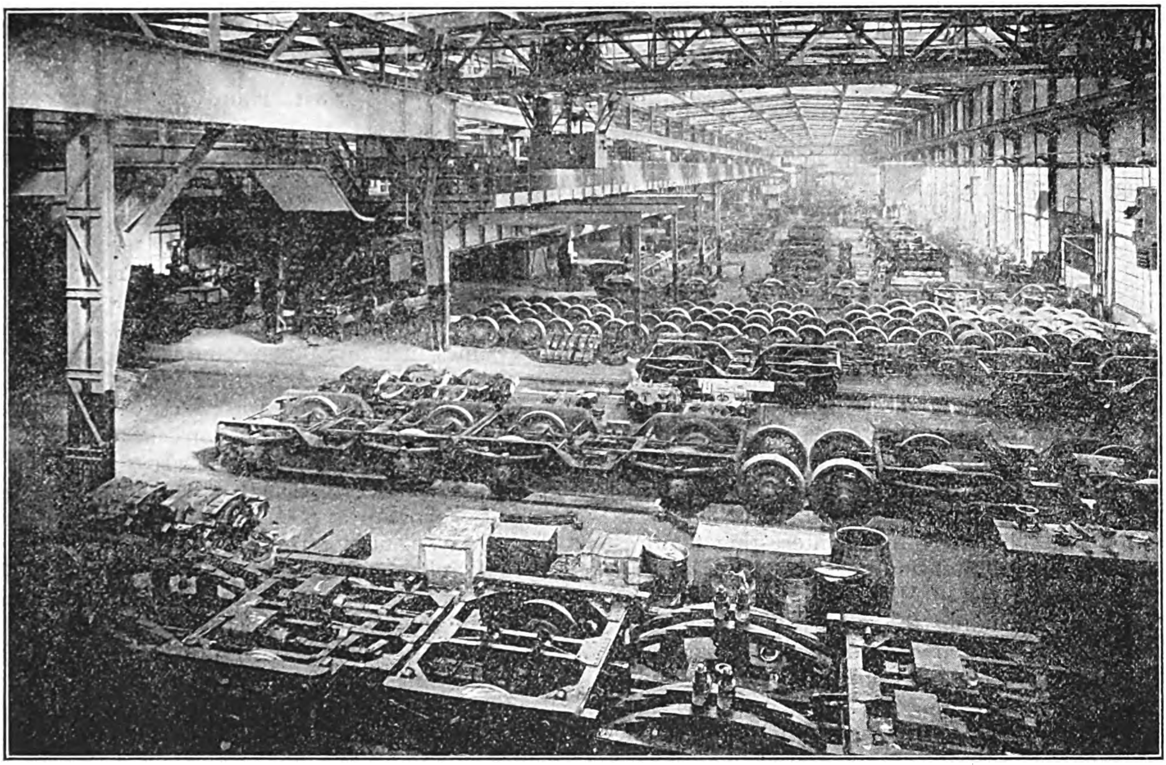

FIG. 29—GERMAN GOVERNMENT RAILWAYS—BERLIN DISTRICT—NEW SHOP FOR SUBURBAN CARS, TRUCK DEPARTMENT.

single-phase at 25 cycles and 6000 volts, but power is transmitted to one substation at 30,000 volts.

In Saxony, at Untersachsenberg, about 3 miles of narrow-gage railway are electrified with 650-volt direct current. Power is purchased at trolley voltage from a municipal steam power station. Two locomotives and 2 motor cars furnish the traction.

General and Future

There are many things of interest to both power and railway companies in the German electrifications. One is the apparent willingness to purchase power or to generate it according to the conditions in each district. Another is the diverse operating conditions of the several sections electrified and the different types of equipment that have been purchased for each.

The use of a separate generating and distributing system for railways has been the subject of much discussion in all countries. It is apparently preferred by the German railway engineers and executives. They justify it as being more reliable and as the cheapest way of securing 16⅔ cycles at the con-

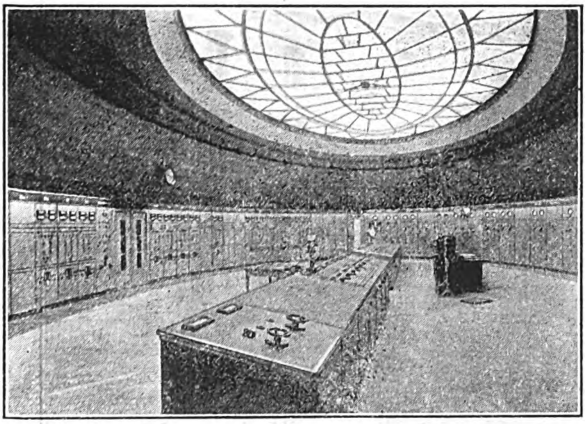

FIG. 30—GERMAN GOVERNMENT RAILWAYS—BERLIN DISTRICT—CONTROL ROOM FOR SUBSTATIONS OF SUBURBAN ELECTRIFICATION.

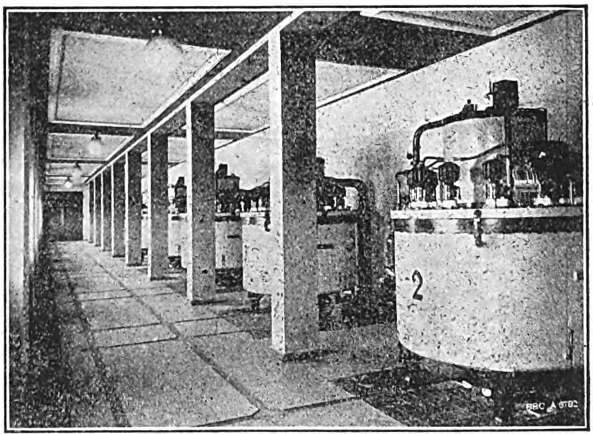

FIG. 31—GERMAN GOVERNMENT RAILWAYS—BERLIN DISTRICT—RECTIFIERS AT MARKGRAFENDAMM SUBSTATION ON SUBURBAN ELECTRIFICATION.

tact line. This is mentioned, not as criticism, but simply to record the impressions received in the field.

Two tendencies of locomotive design were observed here. One is the tendency toward individual-axle drive for high-speed service, doing away with jack-shafts and side-rods. The other is the tendency toward standardization in locomotive design, including the manufacture to standard design by more than one locomotive works. The latter was also mentioned in connection with Sweden and became further impressed on the Subcommittee in other countries.

One of the new standard designs in Germany is of the class 1 D_o 1 for high-speed passenger service. It has 4 twin motors geared to spring quills on the axles. The German engineers expressed considerable satisfaction with this type of drive, including the twin series motor for alternating current.

The motor cars and multiple-unit cars seen in the several districts are substantially built and fine-looking equipment. They have many interesting features for handling the high-tension current on the 15,000-volt motor cars. All of the cars seen, except at Hamburg and including the new rolling stock for Berlin, are of the open type divided by partitions for the different classes and for smoking and non-smoking.

The large program covering the most advisable electrifications has been nearly completed. There will probably be further extensions in the districts above described, particularly in Silesia. About 1600 miles have been studied with the view of electrification in these districts and in the industrial districts of the Rhine. Some of these projected electrifications would connect together the present electrified zones and permit through running of electric trains, but it is not known when they may be undertaken.

Switzerland

Switzerland is a country of special attraction to all students of electrification for two reasons: (1) On account of the early national interest in this subject and the large amount of developmental engineering which was done there, and, (2) on account of the ambitious program of electrification which has been carried out during recent years. As matters now stand, Switzerland has a greater mileage of electrified railway lines than any other country in Europe.

At the end of 1928, 2124 miles, or 62 per cent of the railway route mileage was electrically operated. On the electrically operated sections there was hauled 85 per cent of the total traffic in gross ton-miles of freight and passenger service. These figures include standard-gage railways, narrow-gage railways and rack railways, but not tramways or cable railways. They also include all the lines which were built for electric operation as well as those which were once operated by steam. They show, however, the importance of electric motive power to the whole transportation business of the country.

Coming to the route miles which are classed as electrified, 1180 miles or 51 per cent of the standard-gage lines have actually been changed from steam to electric motive power. With respect to both standard and narrow-gage railways together, the corresponding figure is 1323 miles or 40 per cent. To the 1323 miles should be added, as in the other countries, the extensions of electrified lines into new

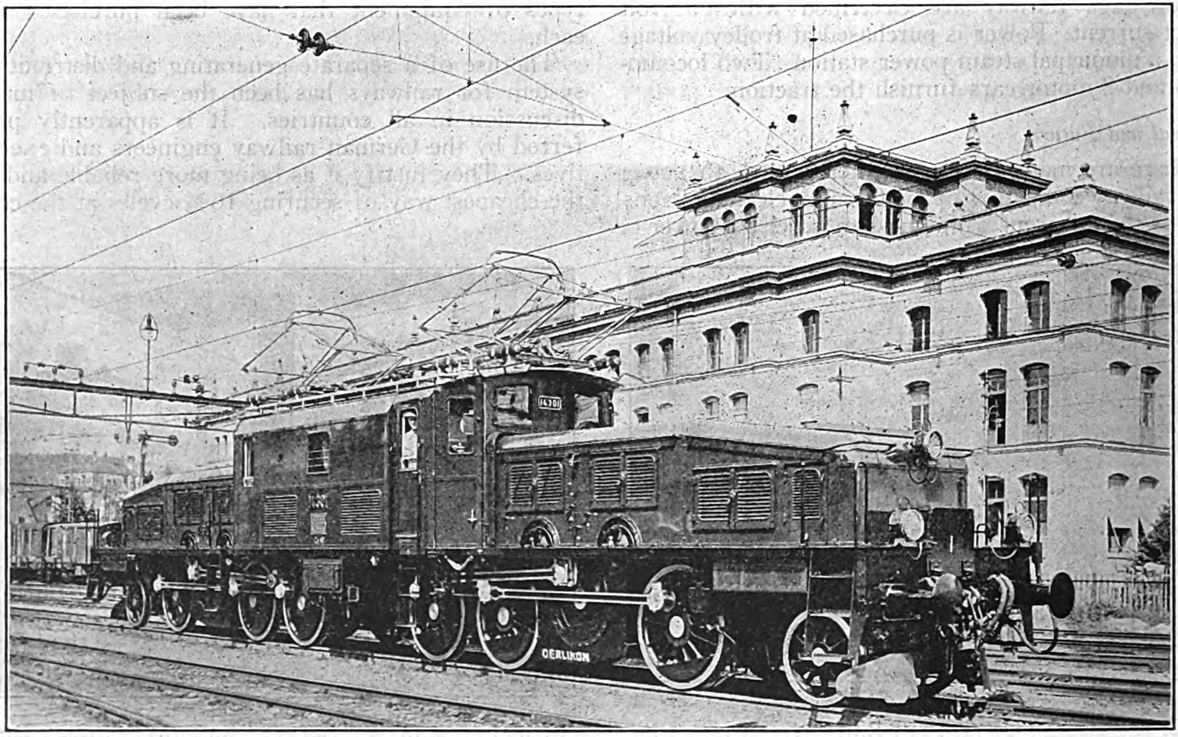

FIG. 32—SWISS FEDERAL RAILWAYS—LATEST TYPE OF FREIGHT LOCOMOTIVE.

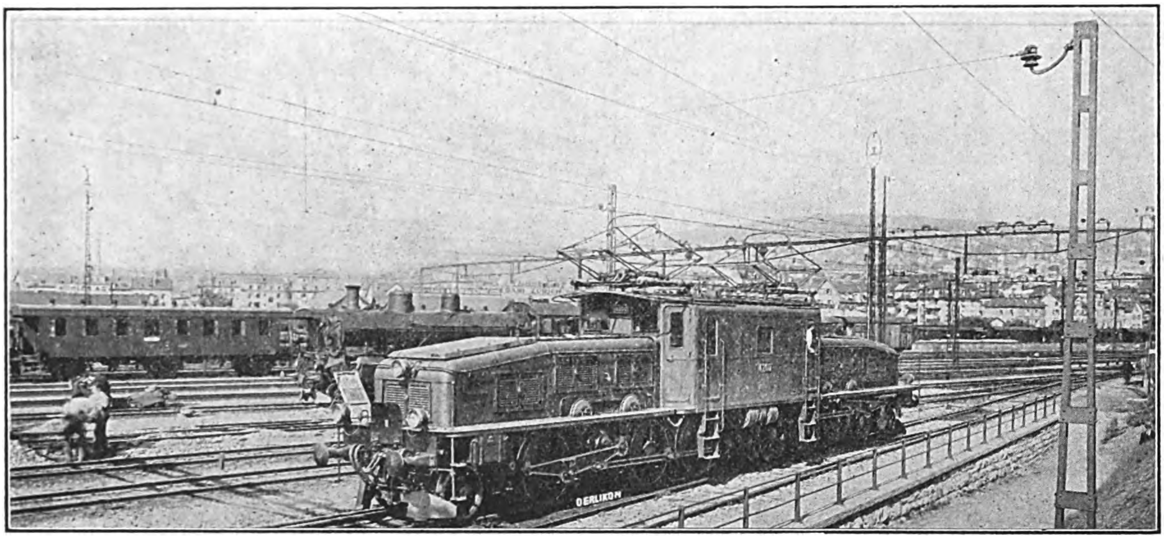

FIG. 33—SWISS FEDERAL RAILWAYS—ANOTHER TYPE OF FREIGHT LOCOMOTIVE.

territory and certain new projects of regular "steam railroad" character and traffic. This results in a total of nearly 1500 miles or 43 per cent of the route miles of the country being classed as electrified.

The reasons behind the change to electricity are several, but the principal one is economic. Switzerland has no coal resources, but has abundance of water power. Before 1900 attempts were made to utilize the water power for railways, and 2 installations were made. One railroad, the Burgdorf-Thun, is worthy of mention for its pioneer work. This road was built by one of the steam railroads and equipped with 3-phase overhead contact line at 750 volts and 40 cycles. The length is 25.5 miles. It still utilizes the same system, although there have been various improvements and replacements of the equipment. The interests in control of this railroad added about 50 per cent to their electrification by a connecting line in 1919.

The meter-gage railways, which perform important service in Switzerland, were among the pioneers to develop and prove the merits of electric traction. One of the early ones was the Montreux-Oberland Railway, which opened 54 miles of line in 1901-1905. This line has many of the features of the other Swiss railways, but has been electric since the beginning. Direct current is used at 1000 volts, and the energy is purchased.

Prior to 1910 the developmental work was done by the smaller railroads, both meter and standard-gage, with the exception of the Simplon tunnel (which is described below under Swiss Federal Railways). In this period there was one significant undertaking in experimental use of high-voltage single phase. A small section about 12 miles long was equipped in 1907 with 15,000 volts at 15 cycles. This was purely a cooperative experiment by some of the electrical manufacturers and lasted 18 months, after which the electrical equipment was dismantled.

Following this experiment the Bernese Alps Railway made plans for utilizing a similar system in the new Loetschberg tunnel, then under construction. It made a trial installation on part of its existing line, commencing in 1910, and extended it to and through the tunnel in 1913, giving it then 47.5 miles of 15,000-volt single-phase electrification. The Bernese Alps Railway is credited with the first commercial installation of this system in 1910. It is interesting to note, however, that the installation was planned to operate on one-half voltage (7500 volts), if necessary, but that this provision was never utilized. The frequency is now 16⅔ cycles instead of 15.

In 1913 the Rhaetian Railway, a meter-gage road, began the installation of an 11,000-volt single-phase trolley at 16⅔ cycles. This work was undertaken in connection with expansion of its system. The first year 30 miles of new electric line were added and about 9 miles of steam-operated line converted to electric. Immediately after the War, conversion of the remainder was pursued vigorously, with result that the whole system of 172 miles has been electric since 1922. They purchase all their power. All service is performed by locomotives.

The economic reasons for electrification, above mentioned, were greatly accentuated during the War when fuel was hard to obtain. Then after the War came an urge to undertake large public improvements as a means of employing workers and providing home industries with business. The elimination of smoke and injurious gases in tunnels was also an important factor in formulating the program.

Swiss Railways have had to cope with a great deal of trouble from the extraordinary number of tunnels, three of which are each in excess of 9 miles. The Simplon and Loetschberg tunnels have been electrified from their openings, in 1906 and 1913 respectively, but the St. Gotthard tunnel was operated for 40 years with steam locomotives.

As a preliminary step toward adoption of electric

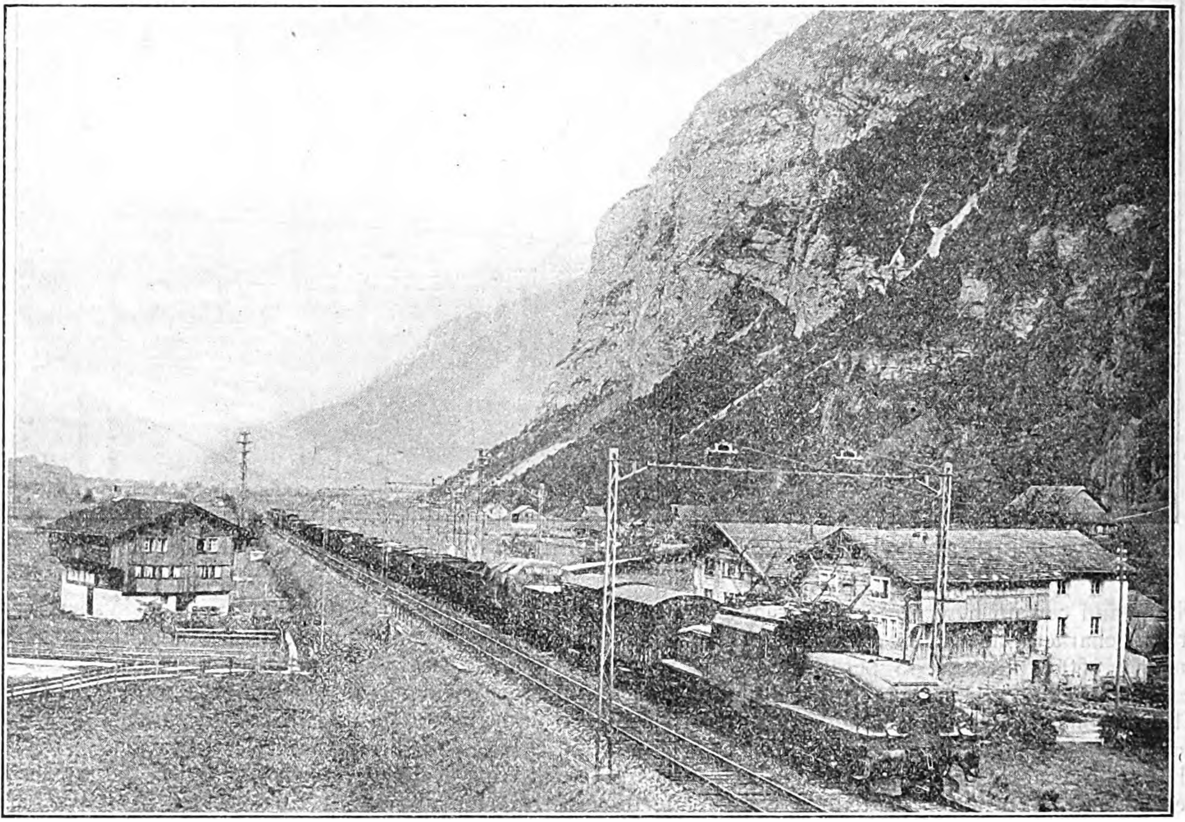

FIG. 34—SWISS FEDERAL RAILWAYS—FREIGHT TRAIN ON ST. GOTTHARD LINE.

traction on a large scale by the Federal Railways, a Research Committee was appointed in 1904. In 1912 this committee submitted a report recommending the use of low-frequency single phase at 15,000 volts. During the intervening period the Federal Government had been active in securing sites for future power plants, and in 1907 a department of the Federal Railways had been established to plan the necessary power developments. The St. Gotthard tunnel electrification was authorized late in 1913, using single-phase current at 15,000 volts and 16⅔ cycles. In February, 1916, the same system of electrification was adopted as standard for the Federal Railways.

A definite program of electrification was laid out for the Federal Railways which has been in effect ever since the War. In the last 5 years a particularly vigorous attempt has been made to complete the program. At the end of 1928 all the most important lines were operating electrically, and the Federal Railways will probably extend electrification on the remainder of its system only very gradually.

Prior to the War there were only about 200 miles of all railways electrified in Switzerland. This increased very slightly during the War. The great growth to nearly 1500 miles now electrified has taken place since 1918, and mostly on the Federal Railways. Their standard system of high-voltage single-phase electrification has been extended to cover nearly 1000 miles of the Federal Railways' lines and about 170 miles of other normal-gage lines. The 15,000-volt single-phase system constitutes 80 per cent of the electrification of Switzerland. The other 20 per cent is divided between several different types of electrification, both alternating and direct current.

There are 2 principal standard-gage railways in Switzerland, the Federal Railways and the Bernese Alps Railway. The latter is also known as the Berne-Loetschberg-Simplon, or more simply as the Loetschberg line. Both of these roads were visited and a brief description of each will follow.

Swiss Federal Railways

As already stated, this railroad operates the principal standard-gage lines of the country, and it handles practically all the international traffic, except such portion as makes part of its journey over the Loetschberg line. It has a number of mountain crossings, including the famous Simplon and St. Gotthard tunnels.

The first important electrification of the Federal Railways was in 1906 when the Simplon tunnel was opened to traffic. During the building of this tunnel, it had been expected until near the end that it would be operated by steam like the older tunnels. There was considerable agitation for it to be operated electrically on account of its great length of 12.3 miles, the longest in the world. The Italians had already achieved some success with 3-phase electrification on main-line railways and urged quite strongly that electric traction be provided. Accordingly the plans were altered to install electric over-

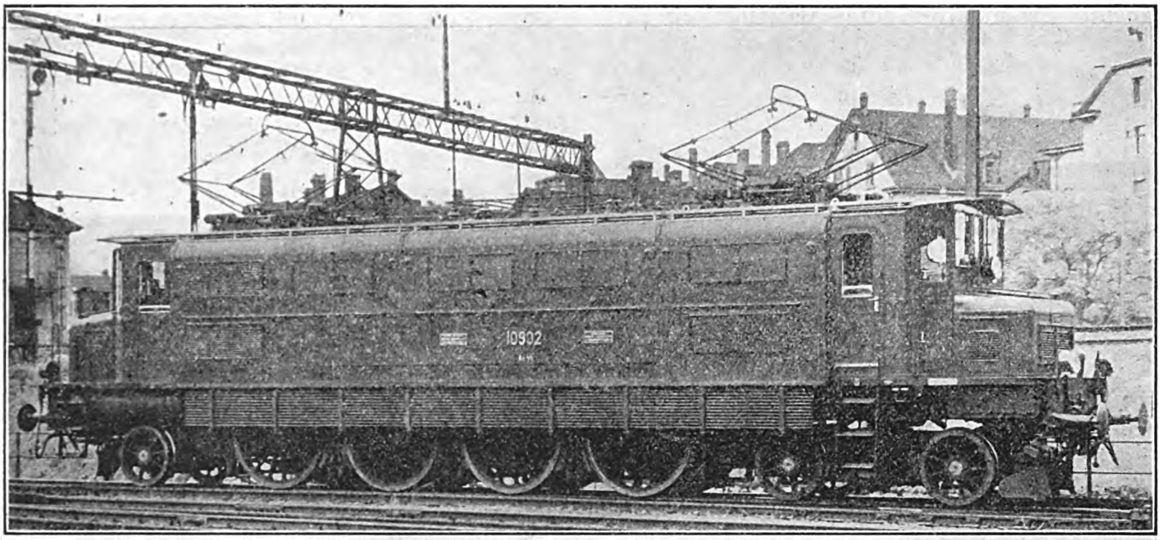

FIG. 35—SWISS FEDERAL RAILWAYS—PASSENGER LOCOMOTIVE WITH INDIVIDUAL-AXLE DRIVE.

head in the tunnel during the last few months before completion. Electric operation was initiated with locomotives borrowed from the Italian State Railways. The 3-phase installation at 3300 volts and 16⅔ cycles is still in operation.

The next important section considered for electrification was the St. Gotthard route which has been mentioned above in its bearing on the general situation. Plans for electrification had been made and construction work started before the War. Due to the difficulties which then ensued, there was not much accomplished for several years. The tunnel itself was changed to electric operation in 1920. The whole project then in hand measured 140 miles from Lucerne to Chiasso, including the tunnel. It was all turned over to electric traction in 1922. It is interesting to note that this stretch of line includes 28.4 miles of tunnels, of which 9.3 miles is in the St. Gotthard bore itself.

In the 5 years since 1923, 70 miles of line have been electrified. The largest amount completed in any year was in 1927 when 300 miles were done. As already stated, this completes the big program of the Federal Railways with all principal trunk lines now electric.

Concurrently with the work on the railways, a

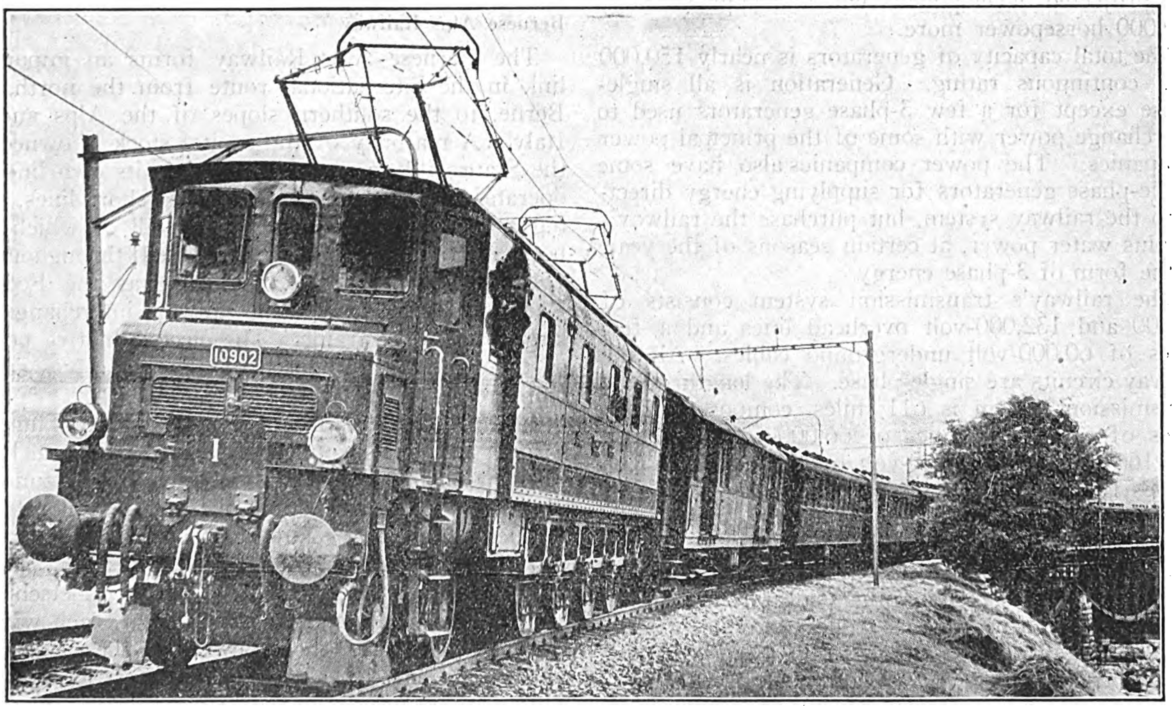

FIG. 36—SWISS FEDERAL RAILWAYS—FRONT VIEW OF PASSENGER LOCOMOTIVE WITH TRAIN.

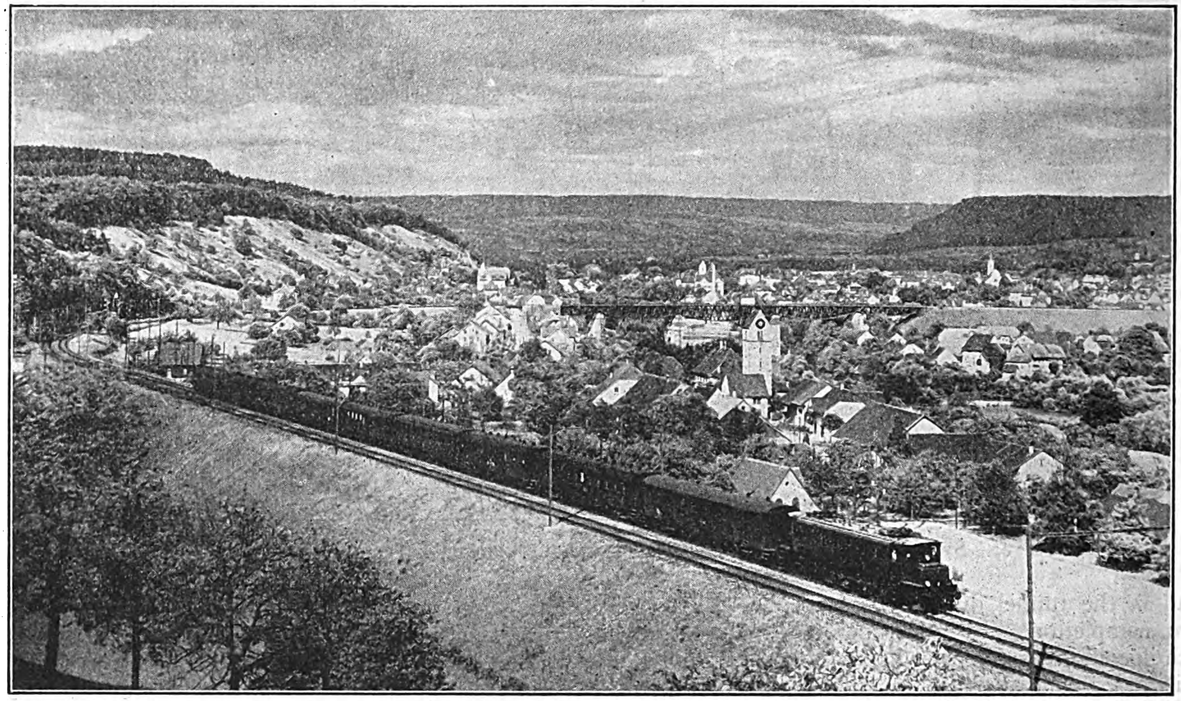

FIG. 37—SWISS FEDERAL RAILWAYS—PASSENGER TRAIN BETWEEN ZURICH AND BASLE.

large power generating and transmitting system has been developed. There are 4 principal power stations, all hydraulic and equipped with Pelton turbines. There are also 2 smaller stations, and property has been acquired for 2 more large stations. The 6 existing water-power developments have a present capacity in excess of 300,000 horsepower, and projected developments will add approximately 200,000 horsepower more.

The total capacity of generators is nearly 150,000 kw., continuous rating. Generation is all single-phase except for a few 3-phase generators used to interchange power with some of the principal power companies. The power companies also have some single-phase generators for supplying energy directly to the railway system, but purchase the railway's surplus water power, at certain seasons of the year, in the form of 3-phase energy.

The railway's transmission system consists of 66,000 and 132,000-volt overhead lines and a few miles of 60,000-volt underground cables. All the railway circuits are single-phase. The length of the transmission system is 611 miles, composed of 38 miles of cable, 407 miles of 66,000-volt overhead, and 166 miles of 132,000-volt overhead. Each line carries from 2 to 8 circuits.

This transmission system feeds 26 substations. Three of these, with capacities of 18,000 or 27,000 kv-a. each, are used to tie together the 66,000 and 132,000-volt lines. The other substations supply 15,000-volt energy to the trolley circuits. They range in size from 3000 to 15,000 kv-a., with individual transformers of 3000 and 5000 kv-a. each.

The motive power in December, 1928, consisted of 364 single-phase locomotives of 10 different types, 56 motor cars of 3 different types, and 7 three-phase locomotives for the Simplon tunnel. There were also 16 storage-battery locomotives for switching. The early tendency of the Federal Railways was to use side-rod drive for all locomotives. In the last few years they have been specifying individual-axle drive for high-speed passenger locomotives.

Bernese Alps Railway

The Bernese Alps Railway forms an important link in the international route from the north, via Berne, to the southern slopes of the Alps and to Italy. A majority of the capital stock is owned by the State of Berne. In addition to its own lines, it operates an equal amount of other short lines, giving a total route mileage of 157, all of which has been electrified. The system used throughout is 15,000-volt single-phase, the same as the Federal Railways with which this railway interchanges a large part of its traffic. The electric motive power of the system is composed of 33 locomotives and 5 motor cars.

The principal main line extends from Thun to Brigue, 52.2 miles, connecting with the Federal Railways at each end. This line includes 35 tunnels, of which the Loetschberg is the longest—more than 9 miles. This is the important part of the system, and further remarks refer specifically to it.

The first locomotives provided for the Loetschberg tunnel were of 90 and 96 tons weight, each with 2 motors. The rated horsepower of the 2 designs was 2000 and 1600 respectively per locomotive. There are now in use on this line 22 locomotives which have been progressively increased in size until the last ones delivered in 1926 are 4500 horsepower each.

There are two of these locomotives, said to be the largest in Europe. They are of the class 1 C—C 1 with overall length about 67 feet and weight 156 tons. Each of the 6 driving axles has a twin motor geared to a spring quill. Control is mechanical-pneumatic. Auxiliary power is 220 volts. This locomotive has a maximum speed of 46.5 m.p.h. One of them can haul a 660-ton train up the 2.7 per cent grade at 40 m.p.h.

Power for the Bernese Alps Railway is furnished by the Bernese Power Co. in which also the State of Berne is the principal shareholder.

Train Heating

Before passing from Switzerland some remarks should be made on electric heating of trains, as practised in Switzerland, and its effect on railroads in other countries. In all of the countries visited (except England and the Netherlands, where electrification of passenger service is confined to motor cars), heater cars are more or less prevalent for heating the passenger coaches. These cars, containing steam boilers, are usually hauled directly behind the electric locomotive.

All of the heating, however, is not done by steam, as a great many coaches have been fitted with electric heaters in addition to the usual steam coils. It is, of course, necessary to retain the steam heating for running on tracks not yet electrified.

In the countries employing high-voltage alternating current, it is customary to have the electric heating supplied from 2 or 3 taps on the main transformer in the locomotive, giving voltages in the range between 600 and 1200 volts. A capacity of 400 kw. is usually provided for this purpose on each locomotive. The heating current has to be cabled back through the train to each car.

In this connection the Swiss have developed a special receptacle and jumper to bridge the gaps between the cars. It is capable of serving also for the 1500-volt direct current of the French railways. One type of receptacle has been standardized for heating-cable jumpers by Austria, France, Germany, Italy, Norway, Sweden and Switzerland.

Another interesting piece of equipment seen in Switzerland is the electric heater truck. These trucks are used for the preheating of trains in the stations. They are mobile on standard-gage tracks. Each one carries a large transformer with essential switching and protective equipment. When located for service, the high-tension side is connected to the 15,000-volt contact line, and the low-tension side is connected to underground cables terminating at the various tracks where trains stand for heating.

Italy

Italy commenced electrification in 1901 and has kept at it almost continuously ever since. As a result the State Railways have more than 1000 miles of line electrified. This, with a few small electrifications, places Italy next to Switzerland among European countries in respect to mileage electrified. Italy has another distinction in having made the most thorough use of 3-phase locomotives of any country in the world.

In addition to the State Railways, there are about 700 miles of electrically operated lines belonging to private railways. These are mostly secondary lines and many are narrow-gage. Some have been electric from the start. They will not be discussed further, except to mention the government subsidy and one important electrification.

There is a standard-gage private railway operating out of Milan which was engaged, at the time of the Subcommittee's visit, in the final stages of its first electrification. This undertaking of the North

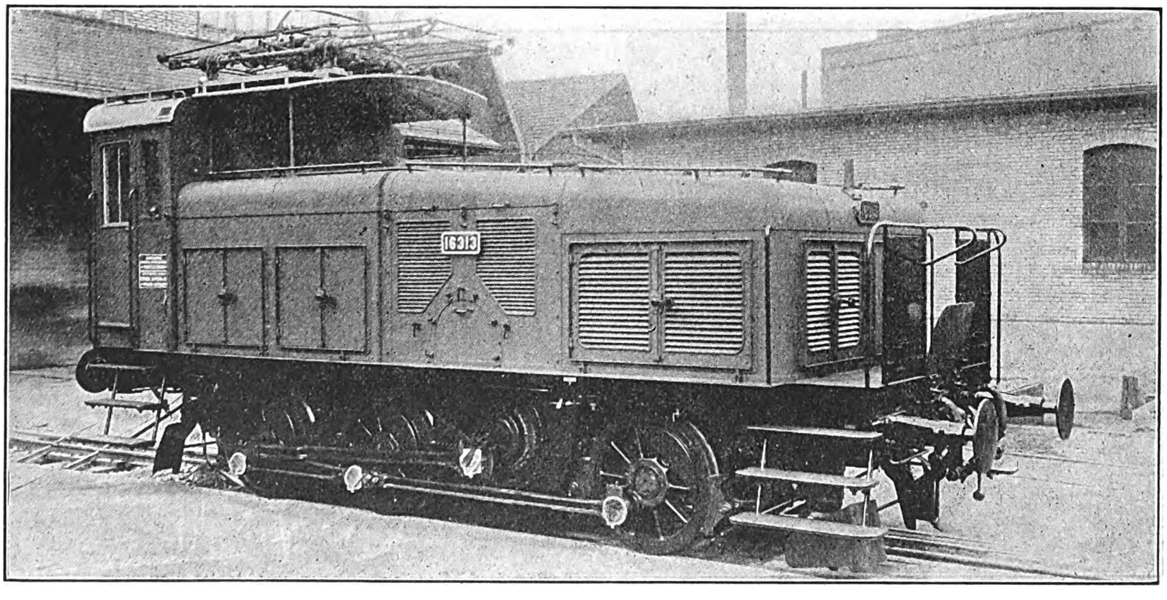

FIG. 38—SWISS FEDERAL RAILWAYS—ELECTRIC SWITCHING LOCOMOTIVE.

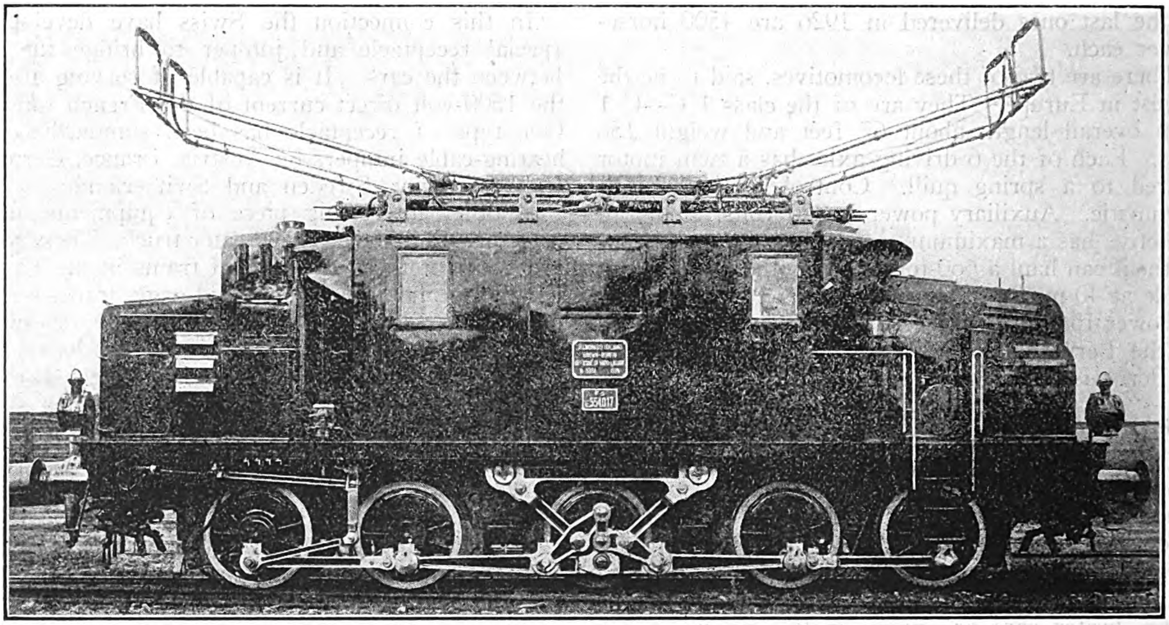

FIG. 39—ITALIAN STATE RAILWAYS—LATEST TYPE OF 3-PHASE, 3700-VOLT, FREIGHT LOCOMOTIVE.

Milan Railway has some very interesting features in the application of high-voltage direct current to suburban service and will be described below.

Since 1924 the Government has offered to private railways a 50-year subsidy to aid in reducing the fixed charges incidental to electrification. There are 2 rates of payment, one for existing lines operating with steam, and a somewhat lower rate for new railways in process of construction.

Italy, like some of the other European countries already described has not much native coal. The country is lined with mountain ranges which offer exceptional opportunities for water-power development. This is particularly true because of the varied climate. The mountains in the north catch the winter snows and retain them through the summer. The water power here is most abundant during warm weather. The mountains in the central and southern part, on the other hand, furnish the most power in the rainy winter season and the least during the summer. By interconnecting these varied districts, it is possible to get a fairly constant supply of hydraulic energy.

The State Railways, as well as privately owned power companies, are active in developing water power and in promoting the interconnection of power sources. There is already a completely interconnected system in the territory between the Swiss border, Leghorn and Florence, extending all the way across the country. Part of the stations and of

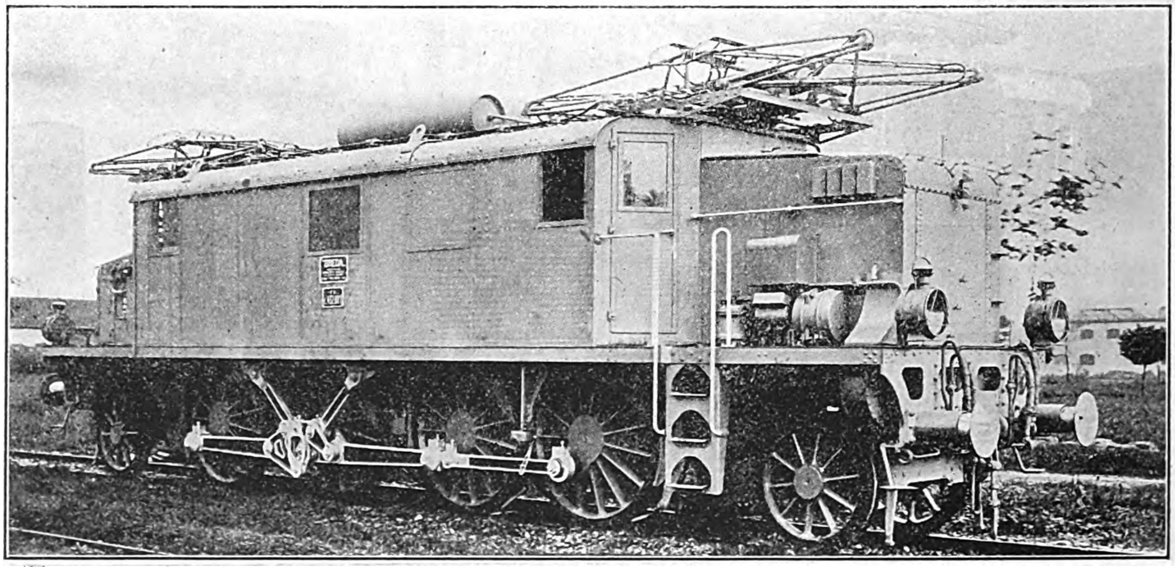

FIG. 40—ITALIAN STATE RAILWAYS—LATEST TYPE OF 3-PHASE, 3700-VOLT, PASSENGER LOCOMOTIVE.

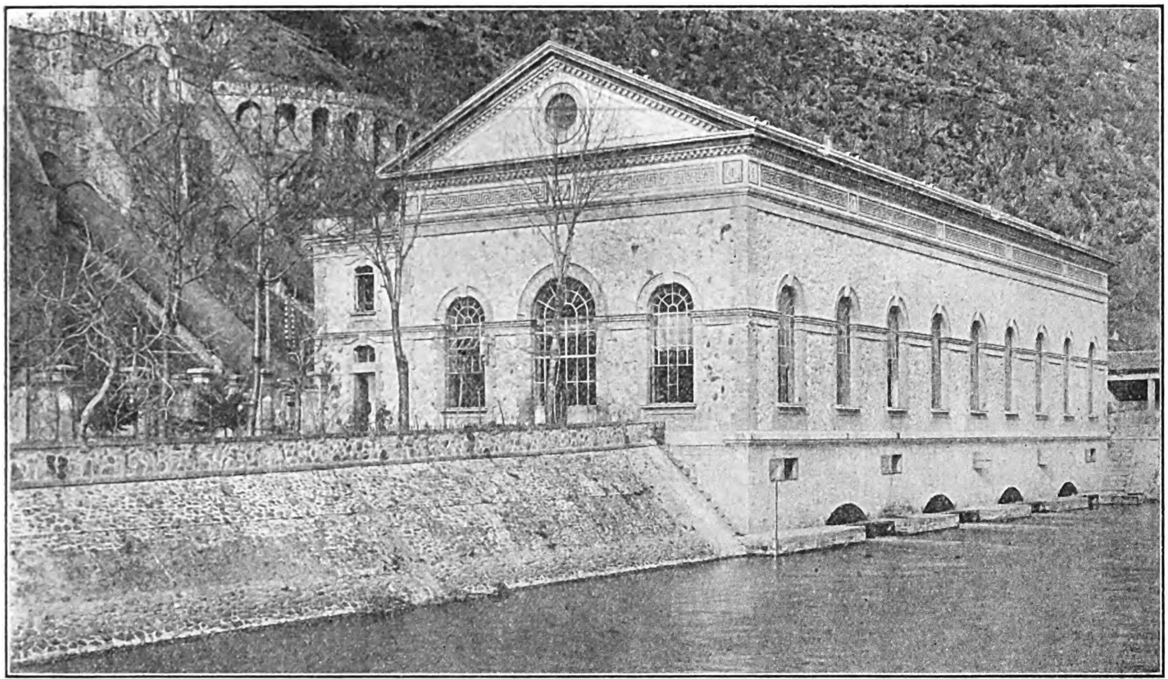

FIG. 41—ITALIAN STATE RAILWAYS—EXTERIOR OF MORBEGNO HYDRO-ELECTRIC STATION

the transmission lines belongs to power companies and part to the State Railways. The railway lines, however, are of low frequency, while the power companies' lines are commercial frequencies. There are a few steam stations located along the west coast, of which one belongs to the State Railways and the others to power companies.

Farther south is another interconnected power network between Rome and Naples, also extending all the way across the country. Since the railway electrification around Rome is at commercial frequency and around Naples is direct current, there is no necessity here for transmission lines of low frequency.

In addition to the economic reason of utilizing water-power resources, there are other important ones which have influenced the State Railways in making their electrifications. In the cases of Milan and Naples, suburban traffic was a factor. Elsewhere the reasons are tunnels and heavy grades. A check of the sections electrified shows that the ones so far converted are in the regions of most difficult operation.

Italian State Railways

At the end of 1928 the State Railways had 1005 miles of line electrified. The systems in use are: (1) 650-volt direct current with third rail, (2) 800-volt direct current, (3) 3000-volt 3-phase current at 15 cycles, (4) 3700-volt 3-phase current at 16⅔ cycles, (5) 10,000-volt 3-phase current at 45 cycles, and (6) 3000-volt direct current. As the last 3 systems are the most important to Italy, the greatest attention will be paid to them after a few words on the history of the development.

In 1897 a commission was appointed by the Minister of Public Works to study electrification of railways for the purpose of reducing the cost of operation. As a result it was decided to try 3 systems of electrification: (1) storage-battery cars, (2) 3000-volt 3-phase current at 15 cycles, and (3) 650-volt direct current with third rail.

The storage-battery coaches were not satisfactory and were abandoned after a few years. The third rail was installed on a suburban line out of Milan in 1901. This is the line now extending to Varese and Porto Ceresio, a distance of 45 miles.

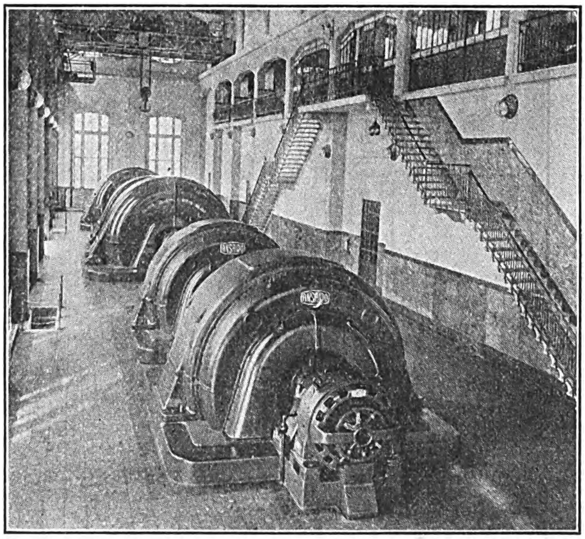

FIG. 42—ITALIAN STATE RAILWAYS—INTERIOR OF SANTA VIOLA SUBSTATION AT BOLOGNA.

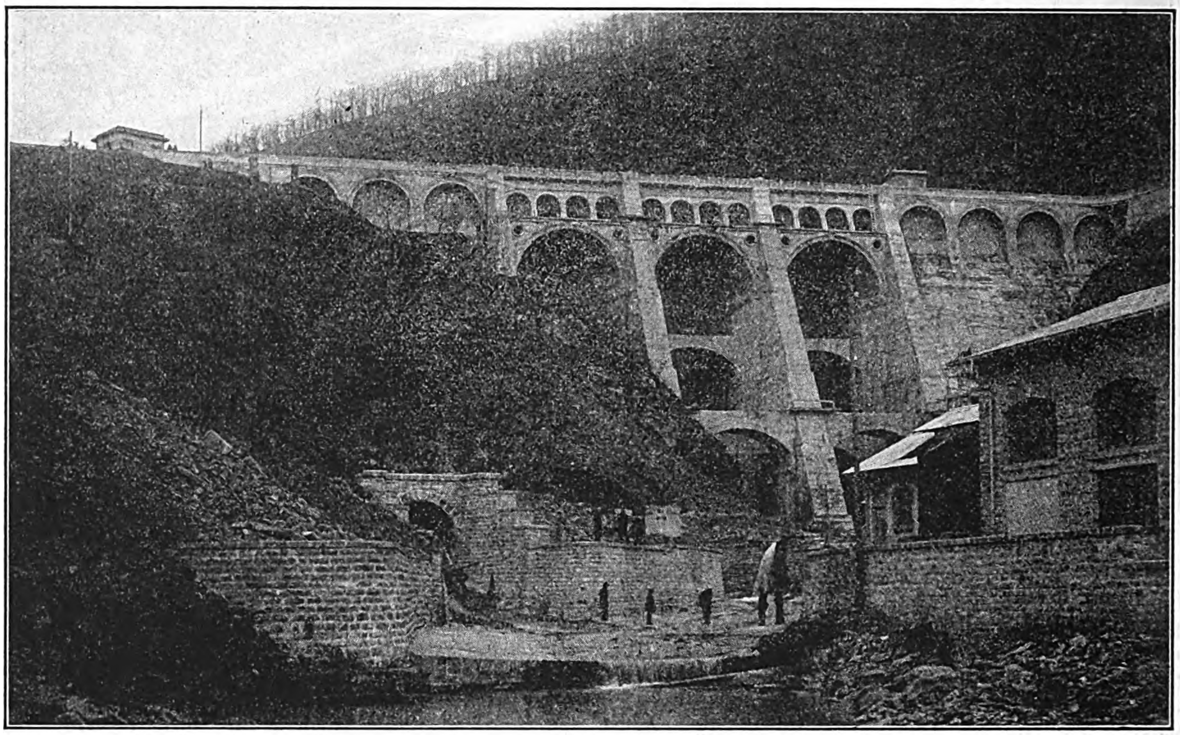

FIG. 43—ITALIAN STATE RAILWAYS—EXTERIOR OF PAVANA HYDRO-ELECTRIC STATION.

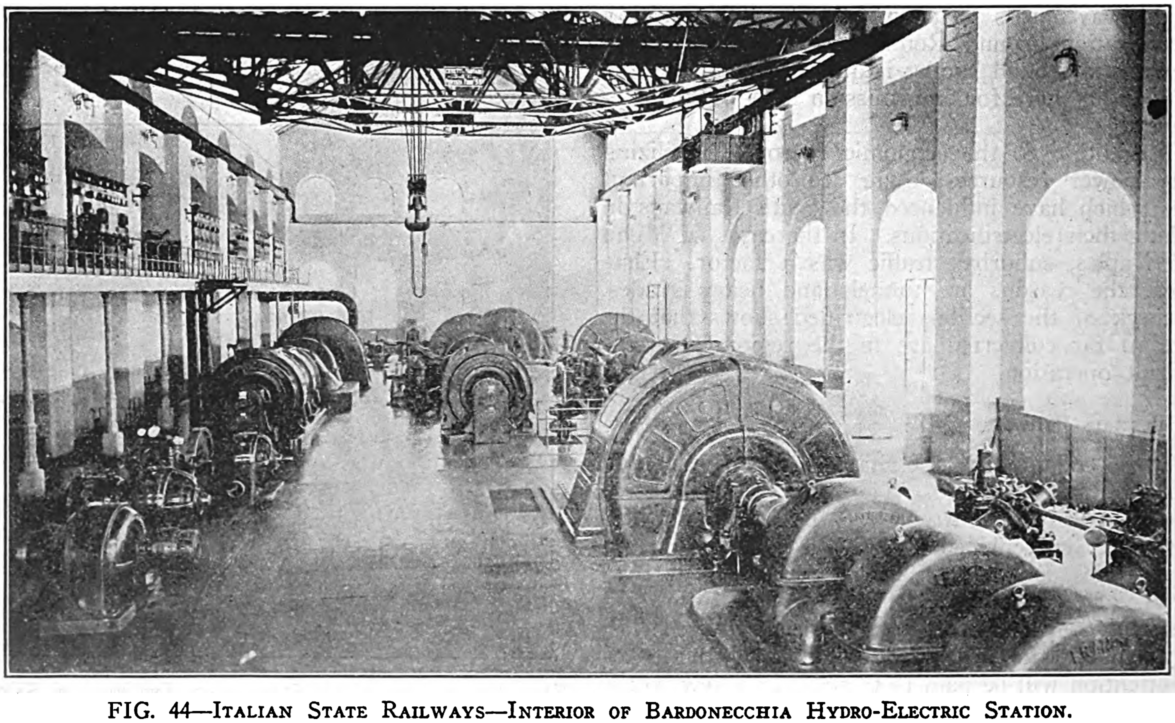

FIG. 44—ITALIAN STATE RAILWAYS—INTERIOR OF BARDONECCHIA HYDRO-ELECTRIC STATION.

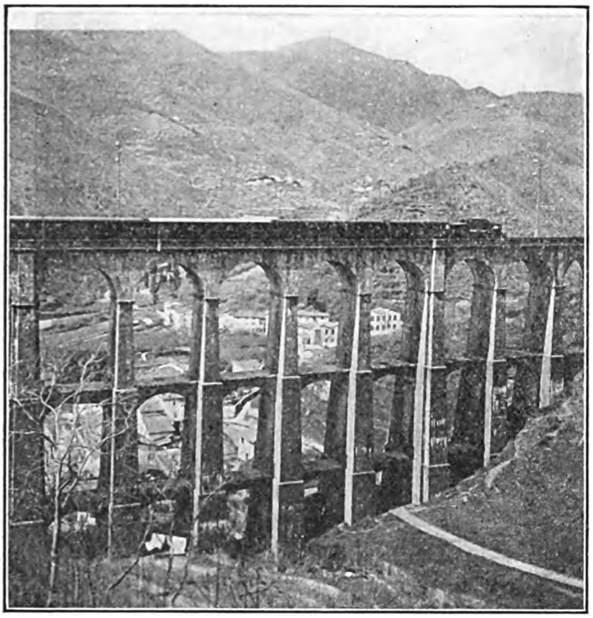

FIG. 45—ITALIAN STATE RAILWAYS—TRAIN ON VIADUCT OF ELECTRIFIED LINE BETWEEN BOLOGNA AND FLORENCE.

The 3-phase system was installed in 1902 on a line somewhat north of Milan between Lecco, Colico, Sondrio and Chiavenna. In 1914 it was continued south from Lecco almost to Milan, where it now terminates at Monza. There are now about 90 miles of this system. The smaller systems are all covered in tables of the general report of this Committee, to which the readers are referred for other details.

In 1911 the first of the present 3 major systems was initiated at Genoa. This is the 3700-volt 3-phase system at 16⅔ cycles. Some of the conditions regarding this installation are interesting. The harbor of Genoa is the principal port of Italy and handles a large tonnage both of import and of export freight. Much of the tonnage must be carried by rail between the port and the inland industrial centers, of which Milan and Turin are conspicuous examples.

The ascent from the harbor is very abrupt and mountainous. Grades are as steep as 3.5 per cent and tunnels numerous. There are two routes from Genoa to Ronco, and on one of these the 3-phase system was installed with very satisfactory results. Train loads were made much heavier, and operating speeds increased. The second line over the mountains was then electrified, and a third line, now under construction, will be electrified also.

In the period since 1911 a great expansion of electrification has occurred in the northwestern part of Italy between Genoa and the French border. At Genoa itself all traffic in and out of the city is now electrified. The only steam power left at Genoa consists of 3 or 4 locomotives retained for special switching. The main through route to France is electrified all the way from Genoa via Turin to Modane, including the long tunnel through the mountains near the border. The Mediterranean route to France via Ventimiglia is now being changed to electric power. On the south of Genoa toward Rome, electric operation prevails as far as Leghorn.

Other 3-phase electrifications have been made between Bologna and Florence, and in the north between Bolzano and Brenner on the Austrian border

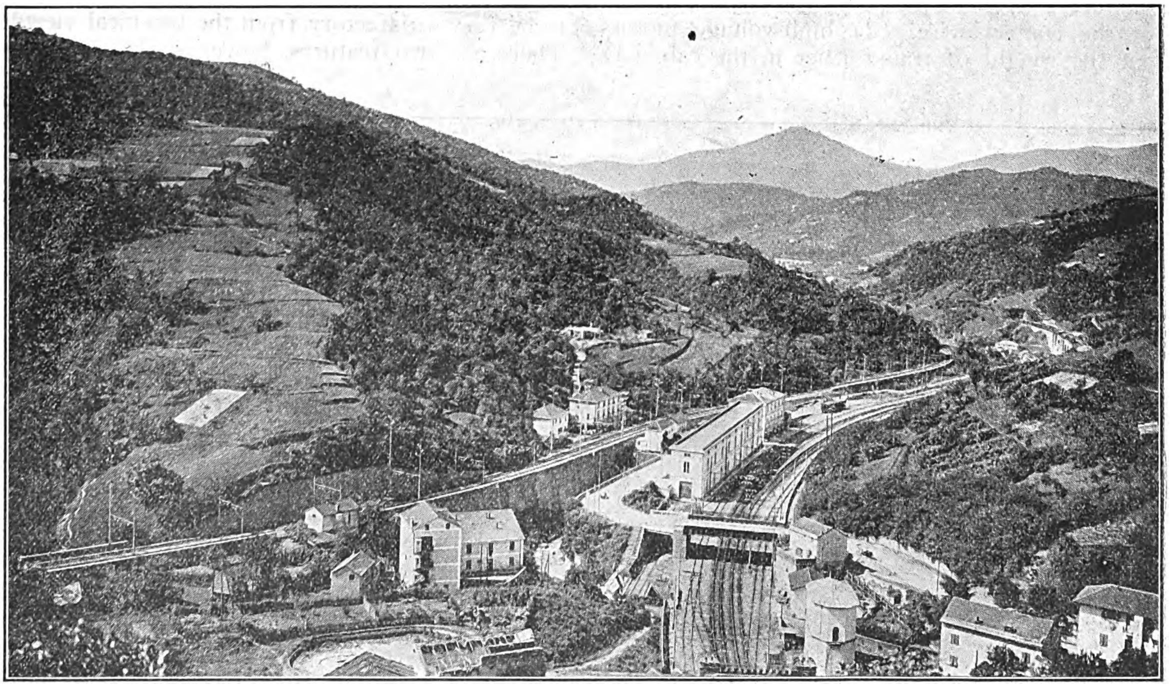

FIG. 46—ITALIAN STATE RAILWAYS—TWO DOUBLE-TRACK LINES ASCENDING FROM THE PORT OF GENOA APPROACH TUNNELS AT MIGNANEGO.

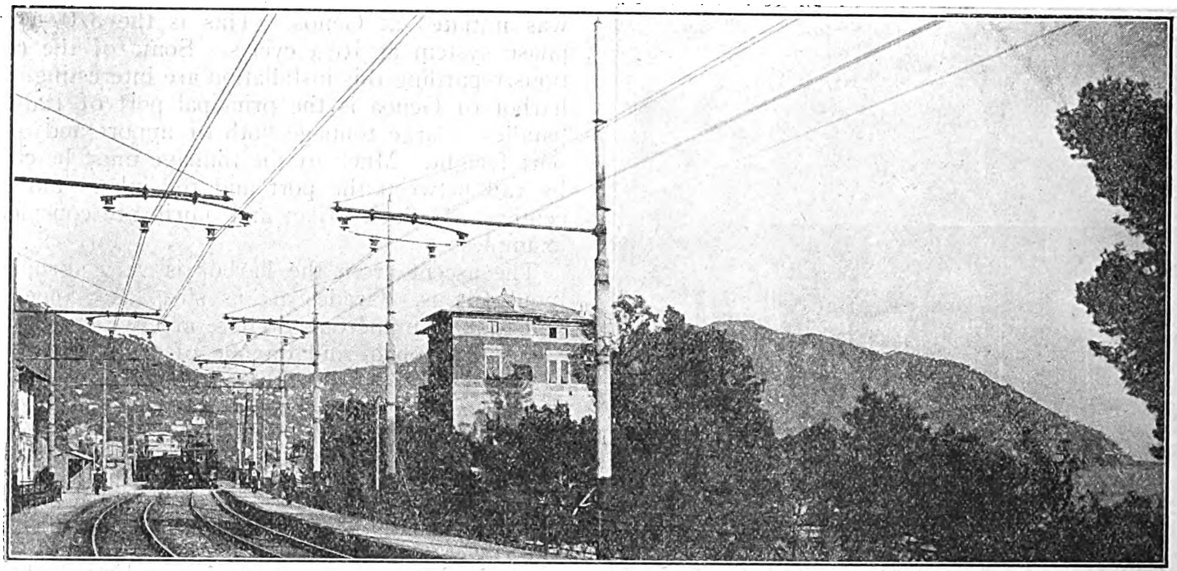

FIG. 47—ITALIAN STATE RAILWAYS—VIEW ON ELECTRIFIED LINE BETWEEN GENOA AND SPEZIA.

where connection is made with trains from Innsbruck, Munich and Berlin. A considerable mileage is now being changed in the neighborhood of Trieste. Summing up the whole activity with regard to the 3-phase lines at 3700 volts, there are 696 miles of this system comprising nearly 70 per cent of the whole State Railways electrification.

This system was adopted in the first place because of the known advantages of 3-phase power for industrial applications. At a time when little was known about heavy electric traction, to enable comparison with other systems, it offered many desirable features: (1) Use of comparatively high voltage at the contact wire, (2) high-voltage motors without the weight of transformer in the cab, (3) several running speeds by changing the number of poles, (4) constant running speed, and (5) automatic regeneration.

The types of locomotive generally used on the 3-phase system all have 2 large motors driving through a Scotch yoke, or equivalent mechanism, to the side-rods. The freight locomotives generally have 5 driving axles, either with or without guiding axles. The passenger locomotives have usually 3 driving axles and guiding axles at each end. These 3-phase locomotives use bow trolleys.

The 3-phase traction at low frequency has been steadily improved since the start and is considered to be very satisfactory from the technical viewpoint. There are two features, however, that have caused

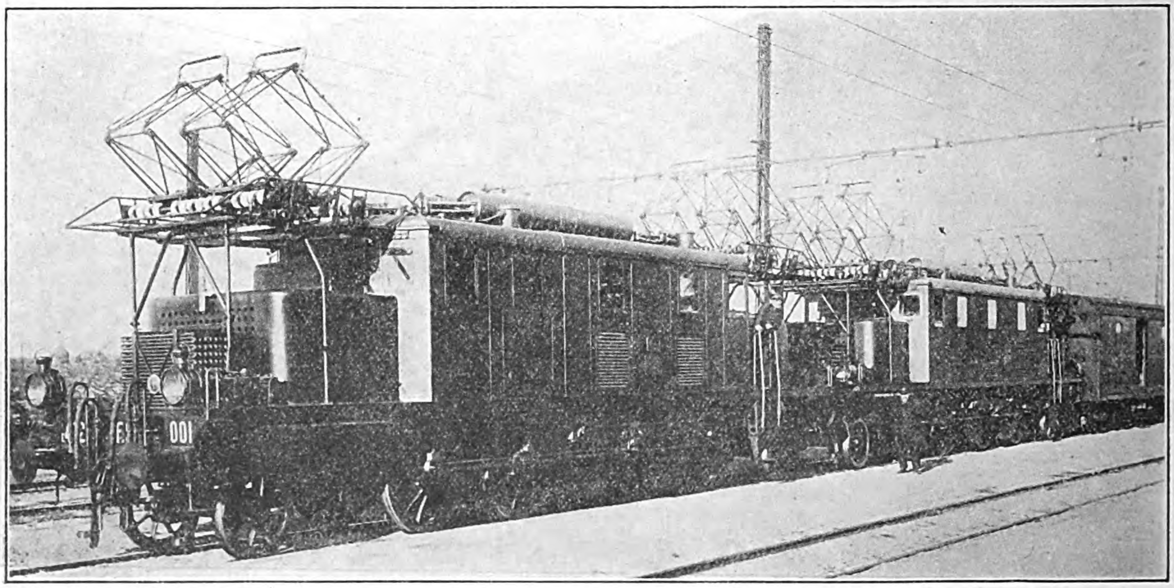

FIG. 48—ITALIAN STATE RAILWAYS—LOCOMOTIVES OF 3-PHASE, 10,000-VOLT ELECTRIFICATION BETWEEN ROME AND SULMONA.

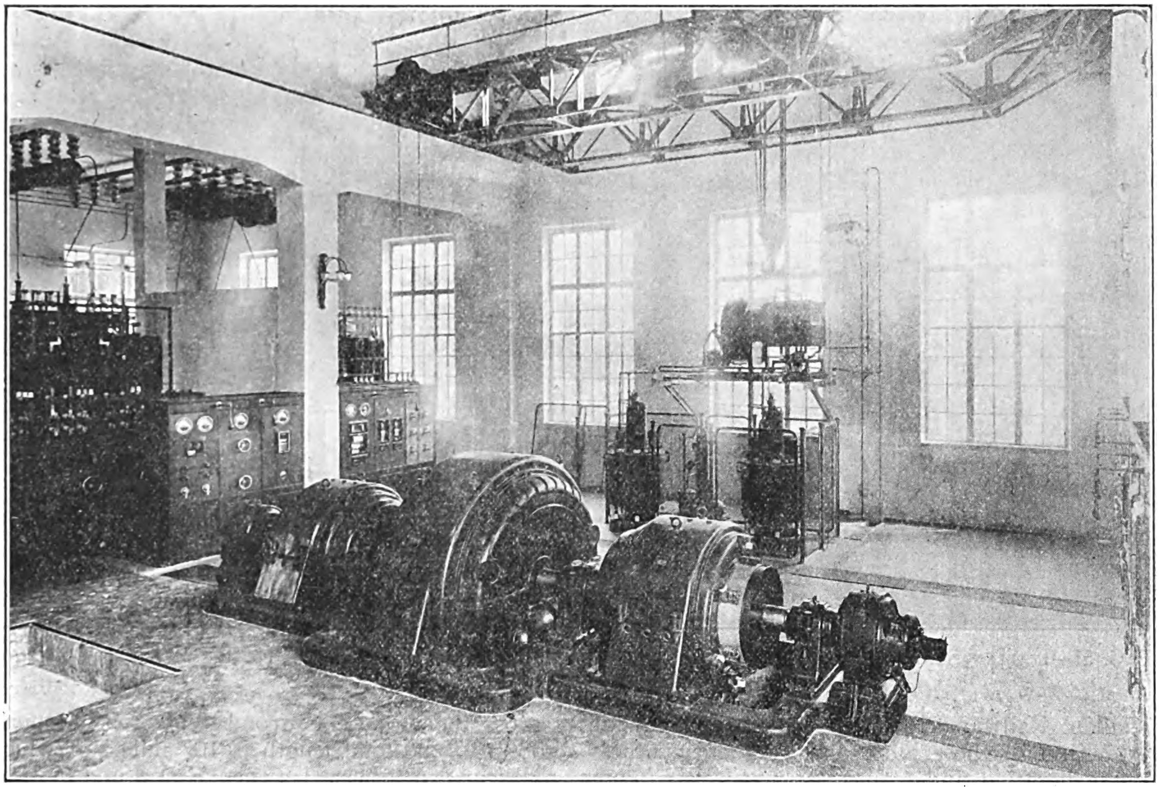

FIG. 49—Italian State Railways—Interior of Apice Substation on 3000-Volt Direct-Current Electrification Between Benevento and Foggia.

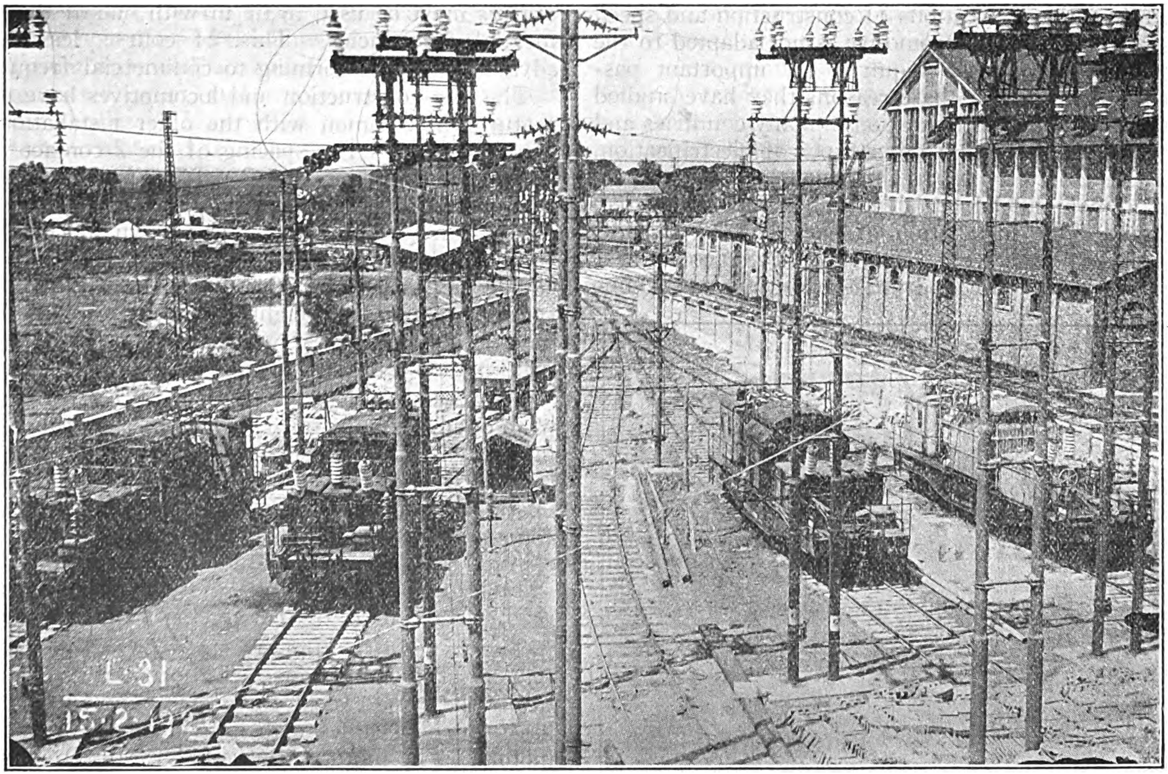

FIG. 50—Italian State Railways—Portable Substations.

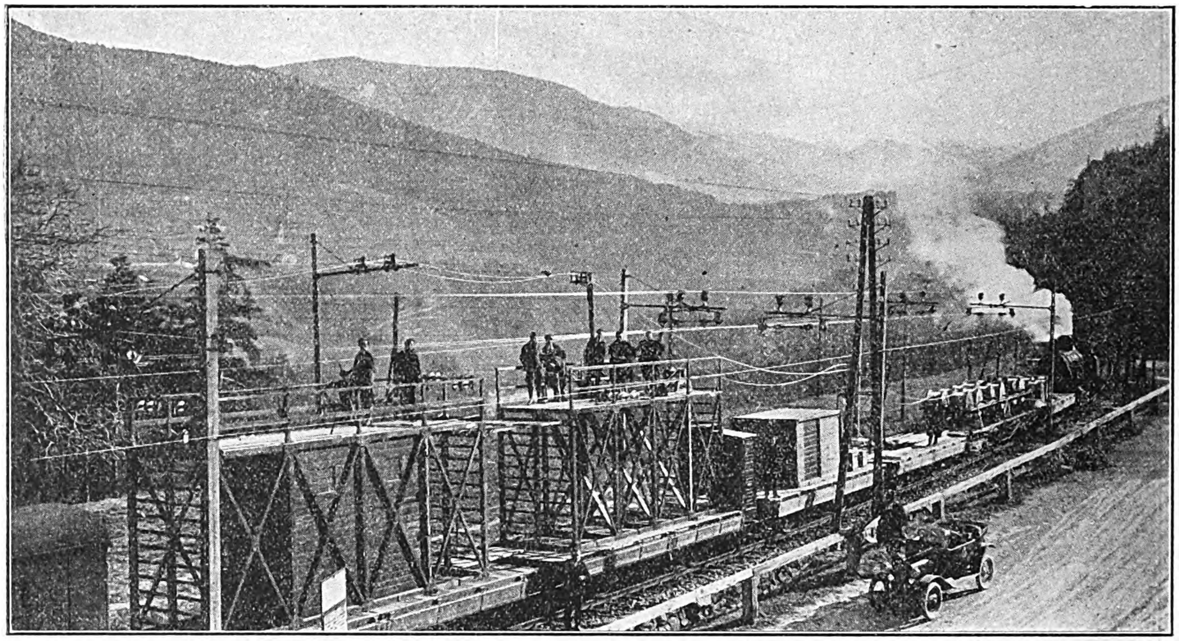

FIG. 51—ITALIAN STATE RAILWAYS—INSTALLING CONTACT LINE ON 3-PHASE ELECTRIFICATION BETWEEN BOLZANO AND BRENNER.

the Italian Railways to consider other types of power. First of these is the low frequency, necessitating generation and transmission separate from the commercial systems of the country, or the use of frequency converters. Second is the fact that the double trolley does not operate well at high speeds, in excess of about 55 m.p.h. Partly on this account, and also due to limitations of construction and speed control, the 3-phase locomotive is not adapted to the very high speed now required for important passenger service. For these reasons they have studied other systems of electrification in many countries and finally decided to try 2 other types of electrification.

These 2 new types are high-voltage 3-phase current at commercial frequency and 3000-volt direct current. One installation of each has been made, and these 2 lines were visited by the Subcommittee.

For the 10,000-volt 3-phase experiment, the line across the mountains from Rome to Sulmona was chosen. The total length is 107 miles, of which 67 miles are in service between Rome and Avezzano. The frequency is 45 cycles. Part of the power is generated by the railway and part purchased. As there are 2 commercial frequencies in this part of the country—namely, 42 and 45 cycles—motor generators must be used to tie in with one of the commercial frequencies. This, of course, lessens the advantages of conforming to commercial frequency.

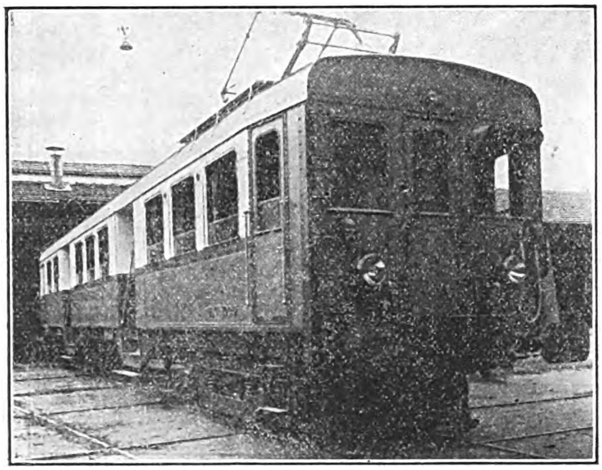

FIG. 52—NORTH MILAN RAILWAY—MULTIPLE-UNIT CAR FOR 3000-VOLT DIRECT CURRENT.

The line construction and locomotives have many features in common with the older installations at low frequency. The spacing of the 2 contact wires is somewhat greater, and 2 narrow pantographs are used instead of a bow trolley. Each locomotive carries a transformer for stepping down the line voltage. Passenger locomotives of class 1 D 1 have 4 coupled axles, weigh 100 tons and have a maximum speed of 62 m.p.h. Freight locomotives of class 1 E 1 have 5 coupled axles, weigh 84 tons, and have a maximum speed of 31 m.p.h.

The installation of 3000-volt direct current is planned to extend from Naples across the mountains to Foggia, a distance of 122 miles. The section between Benevento and Foggia is already in operation, 63 miles. Power is purchased from 2 commercial power systems, both using 45 cycles. The railway has its own transmission line feeding 3 substations. Both motor-generators and mercury arc rectifiers are used for conversion to direct current.

Two types of locomotives are provided for passenger and freight trains. The locomotives are practically the same except for gearing and speed. Both have 6 driving axles with individual nose-suspended motors. The motors are wound for 1500 volts and connected two in series. They have forced ventilation. Each motor is rated 400 horsepower, or a total of 2400 horsepower for the locomotive. The freight locomotives weigh 95 tons and have a speed of 28 m.p.h. The passenger locomotives weigh 102.5 tons and have a speed of 47 miles.

Future plans of the State Railways which have already been announced include 285 miles of electrification now under way and 325 miles still in the planning stage. The 285 miles in process is divided between the 3 important systems as follows: 185 miles in the 3-phase district north of Florence, 40 miles in completion of the 10,000-volt 3-phase line east of Rome, and 60 miles in completion of the 3000-volt direct-current line east of Naples. In general the 3-phase system at 16⅔ cycles will be hereafter used in the northern part of the country where so much of it is already installed. In the central and southern part it is now the intention to use 3000-volt direct current for important main lines where high speed is desirable.

The heating of passenger coaches on the State Railways has, up to this time, all been done with heater cars carrying coal-fired boilers. On the latest passenger locomotives being delivered in 1928, an oil-fired boiler is placed at one end of the cab.

North Milan Railway

This is a standard-gage railway operating a system of about 156 miles of line in the district to the north of Milan, between Milan and the Lakes Como and Maggiore. It has a large suburban passenger business and a 2-track approach to the Milan terminal. In order to relieve congestion and to speed up the suburban service in competition with other means of travel, the management has adopted electricity for operation of the lines nearest Milan. The installation was well advanced at the time of the Subcommittee's visit, and it was expected to initiate the new service in May, 1929.

Direct current at 3000 volts has been chosen, using an overhead contact line. Power will be purchased from a neighboring water-power company.

One substation has been built about 4 miles from Milan. Power will be received at 23,000 volts, 42 cycles, over 2 circuits. There are 4 groups of mercury arc rectifiers of 2000 kw. each. Rectifiers and feeders are protected by high-speed circuit breakers.

The contact line has catenary suspension outside the Milan terminal zone. In the latter case on account of low clearance, simple suspension from bracket arms is used. On the main line the pivot type of bracket is used for the catenary with counterweighted messenger and contact wires.

The present extent of this electrification embraces 2 routes from the Milan terminal over a common line to Bovisa and then branching to Saronno and to Meda. The length is 31 miles, all double track. Multiple-unit cars will be used for the suburban service and locomotives for other passenger and freight trains. Current collection will be by pantographs.

Eight multiple-unit motor cars have been purchased and 8 driving trailers. The motor cars weigh 58.5 tons and seat 78. The trailers weigh 42 tons and seat 102. Both kinds of cars have 2 large side doors for rapid loading and unloading.

Each motor car has 4 motors of 185 horsepower each, connected permanently two in series. Motors are nose-suspended, and axles have roller bearings. The motor cars have a maximum speed of 62 m.p.h., and it is expected to maintain schedule speeds of about 28 to 38 m.p.h. for the different kinds of trains. Control is of the camshaft type, electropneumatically operated and with automatic acceleration. Control and lighting currents are furnished by a 36-volt battery and chain-driven axle generator. The air compressor and car heaters are operated at line voltage.

In addition to the driving trailers there will be ordinary trailers and baggage cars fitted with control cables, heating conductors, etc. It is proposed to convert some of the old 2-axle coaches into 2-coupled units with large side doors. These units will weigh 25 tons each and seat 100.

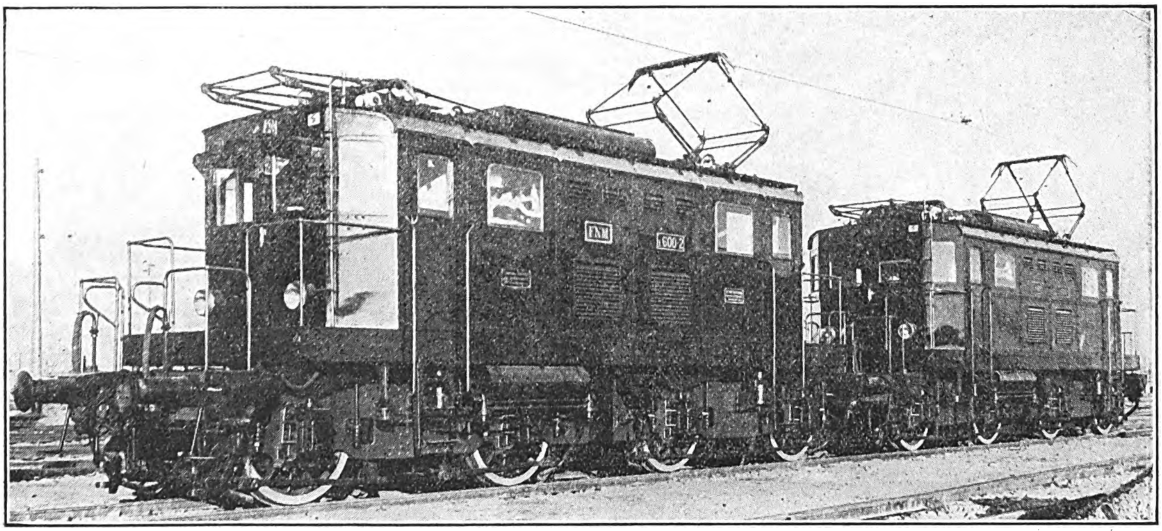

FIG. 53—NORTH MILAN RAILWAY—FREIGHT LOCOMOTIVES FOR 3000-VOLT DIRECT CURRENT.

The 4 locomotives which have been purchased for freight service weigh about 70 tons each, with all weight on drivers. There are two trucks with an articulated joint between. Each of the 4 axles has a 350-horsepower motor driving through elastic gearing. The one-hour rating is approximately 20,000 lb. tractive effort at 25 m.p.h. The maximum speed is 46.5 m.p.h. The traction motors are permanently connected two in series. Auxiliary circuits are fed from a dynamotor.

France

Electrification in France had its start in 1900, when the State Railways electrified a small part of its suburban system and the Paris-Orleans Railway electrified the tunnel between its Quai d'Orsay and Austerlitz stations. Both of these railways used the ordinary type of third-rail construction, and both made further short extensions prior to the War.

The Midi Railway in the extreme southern part of France commenced electrification in 1910 when a short, new, narrow-gage line was opened, using a third rail of 850 volts. This was followed by the electrification of several branch lines with high-voltage single-phase overhead, and construction of the same type had been started on a section of main line when the War caused a halt.

The Paris-Orleans and Midi Railways desired to make extensive expansion of their electrifications, and the Paris, Lyons & Mediterranean Railway also proposed a large program for conversion to electric traction. As a result the Government, shortly after the Armistice, appointed a committee to determine how electrification shall be arranged for the greatest good of the country. The committee made its report, which was adopted by the Ministry of Public Works in August, 1920. This very long report in general had 3 important conclusions. First, 5500 miles of route on these 3 large railway systems were judged suitable for electrification. Of the suitable mileage 5000 miles were already in operation with steam locomotives, and 500 miles were to be built new. Second, direct current at the tension of 1500 volts should be used with either overhead conductor or third rail. A higher pressure of 3000 volts was made permissive for special cases. Third, energy should be supplied to the substation as 3-phase and 50-cycle, thereby conforming to the standard already set for commercial power systems.

It should be stated that the 3 railways involved in this large program all operate to the south of Paris, in a region composing more than half of France. The other railways were not included in the discussion, and except for the Paris suburban lines of the State Railways are not yet engaged in electrification.

The conditions to the south of Paris are most in accord with that policy of national economics which dictates a reduction of coal imports. The territory is traversed by several mountain ranges which make heavy grades on the much traveled lines. This part of the country is farthest from the domestic coal resources and is moreover well supplied with natural water-power sites. These sites are being developed both by the railways and by power companies, in some cases cooperatively. The Government has aided the railways in their electrification programs by making favorable concessions of water-power privileges.

As a result of the decision above described, the Paris-Orleans and Midi Railways changed their existing electrifications to 1500-volt direct current. The P. L. M. launched its program on the same basis.

Paris-Orleans Railway

In 1900 this company inaugurated electric operation of a double-track tunnel, about 3 miles long, connecting its 2 principal Paris stations, Quai d'Orsay and Austerlitz. The system used was third rail

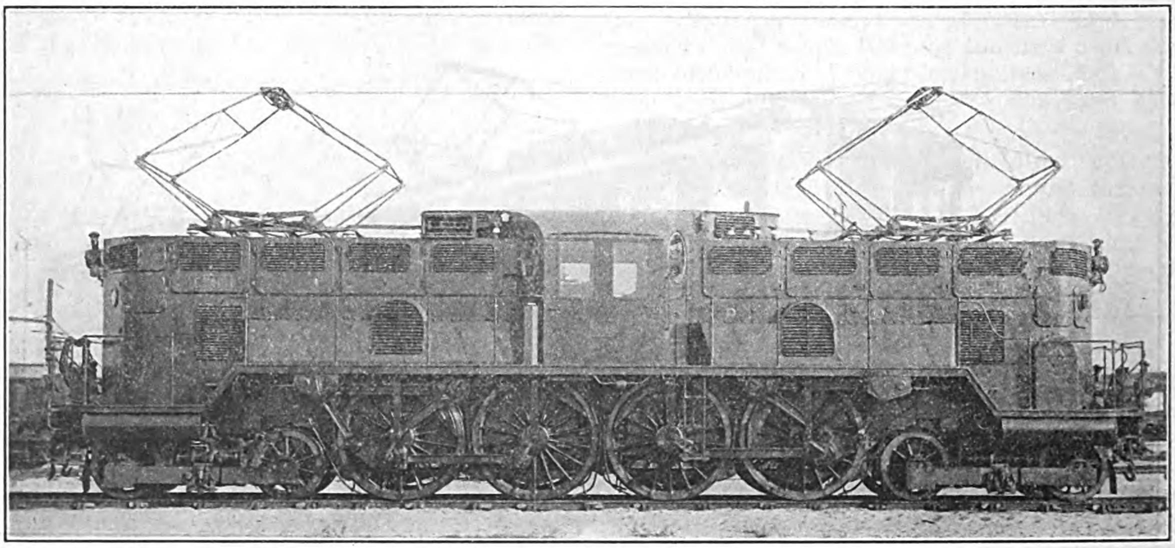

FIG. 54—PARIS-ORLEANS RAILWAY—HIGH-SPEED PASSENGER LOCOMOTIVE WITH SIDE-ROD DRIVE.

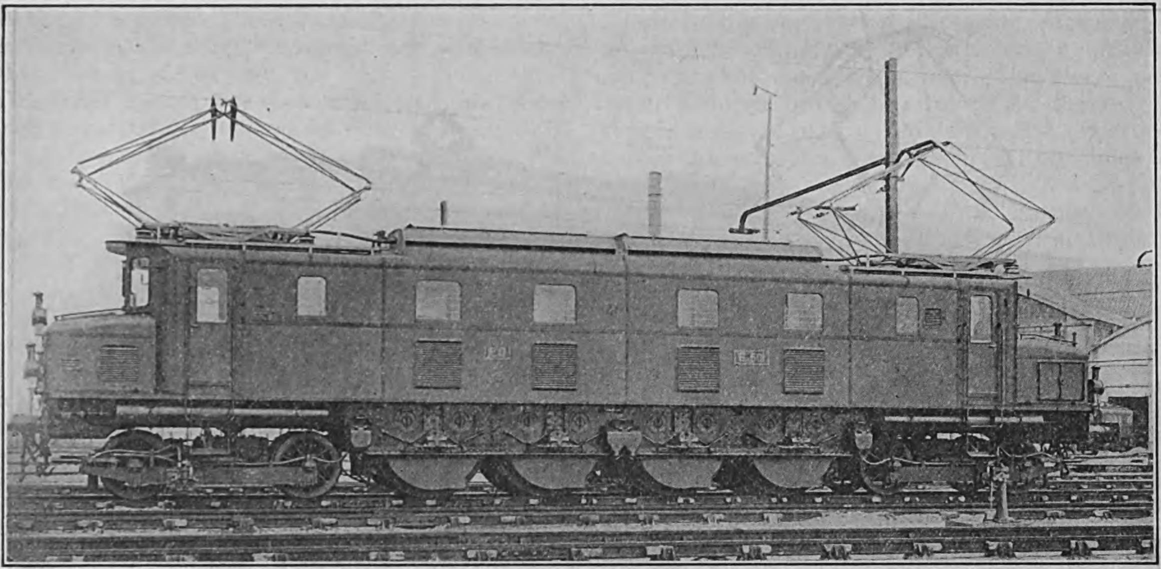

FIG. 55—Paris-Orleans Railway—High-Speed Passenger Locomotive with Individual-Axle Drive.

at 600 volts. In 1904 electric service was extended from Austerlitz to the nearby suburb of Juvisy, about 14 miles. This line has since been provided with overhead contact line of 1500 volts and the new system extended to Vierzon, 126 miles from Paris. Of this the 35 miles from Austerlitz to Etampes is 4-track and the remainder double-track. There are also 2 branches electrified. The total is about 150 miles of route and 600 miles of all tracks. The general type of overhead construction is compound catenary.

Suburban service is furnished by multiple-unit trains. The cars for this service are quite modern and of all steel construction. There are 80 motor cars and 80 trailers. The motor cars each have four 250-horsepower motors (750 volts per motor) and electro-pneumatic control.

For the distance trains there are 10 high-speed passenger locomotives of several different types. There are 193 freight locomotives, which can also be used for passenger trains not requiring the highest speed.

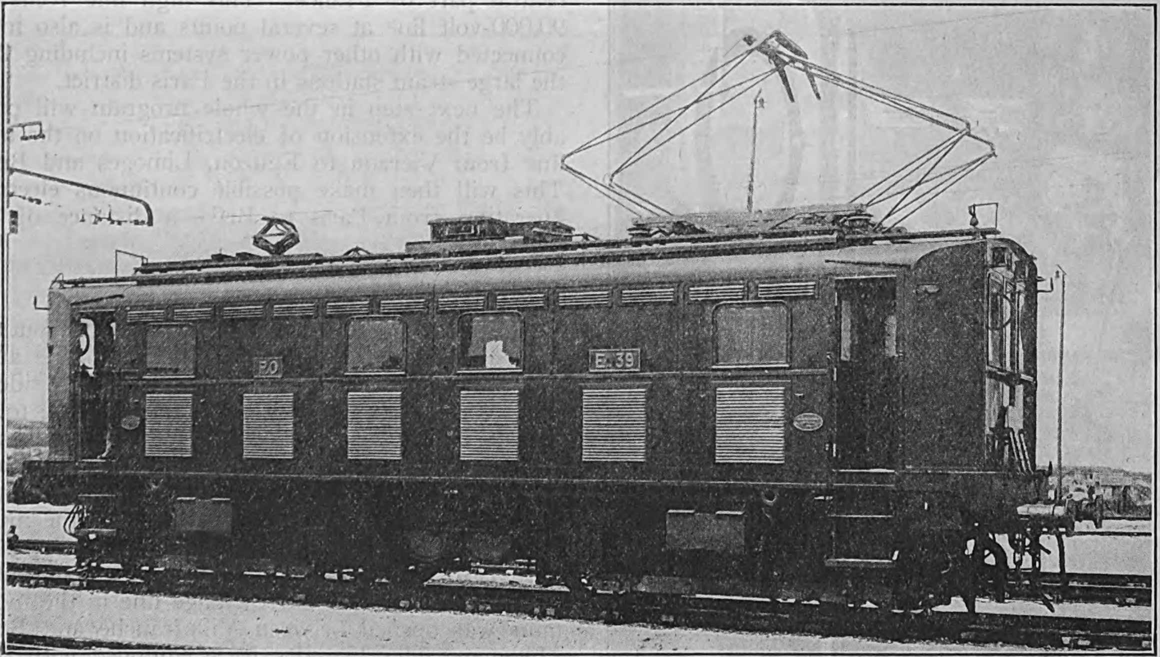

FIG. 56—Paris-Orleans Railway—One Type of Locomotive for Combination Freight or Local Passenger Service.

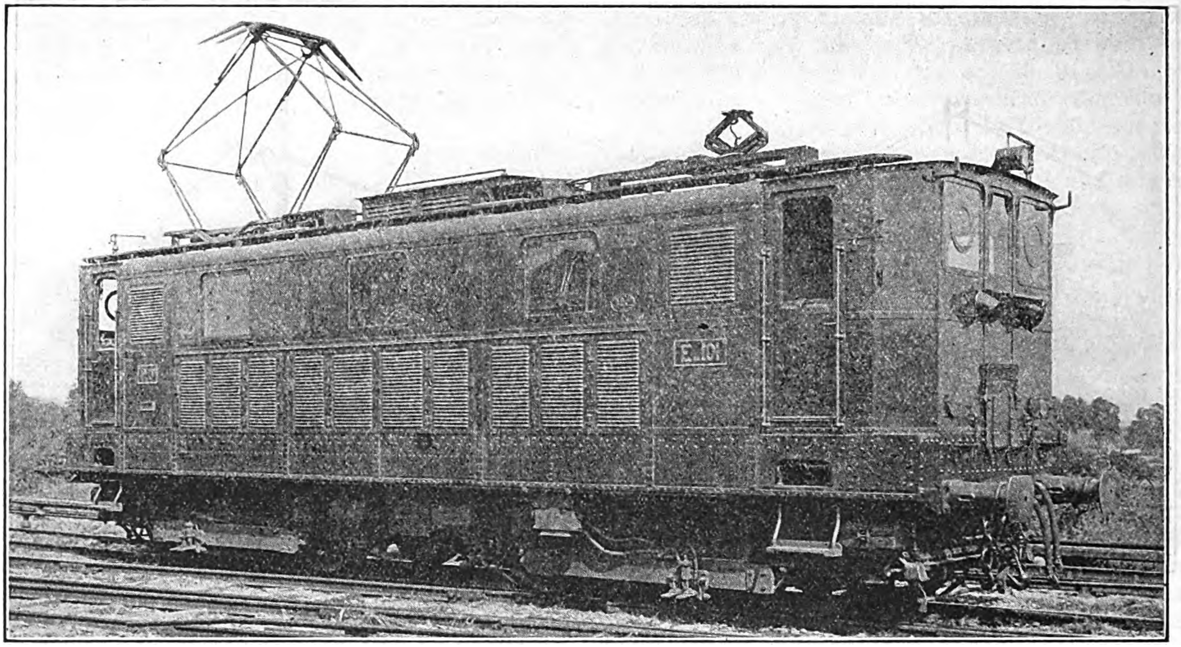

FIG. 57—PARIS-ORLEANS RAILWAY—ANOTHER TYPE OF LOCOMOTIVE FOR COMBINATION FREIGHT OR LOCAL PASSENGER SERVICE.

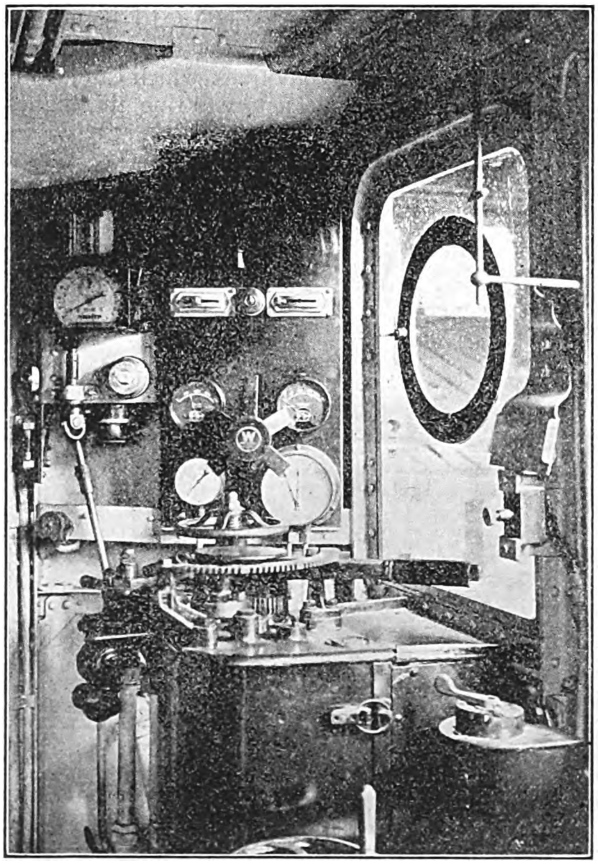

FIG. 58—PARIS-ORLEANS RAILWAY—DRIVER'S CAB FOR LOCOMOTIVE IN FIG. 56.

There are 11 substations containing rotary converters, 750 volts each and connected two in series. Power is supplied to the 2 most northerly ones from one of the power companies in Paris. Power is supplied to the others from the railway company's own transmission lines. There is a system of 90,000-volt lines to feed the substations and a trunk line of 150,000 volts bringing the power to Paris from the railway's distant water-power stations in the south-central part of France. This high line feeds the 90,000-volt line at several points and is also interconnected with other power systems including 2 of the large steam stations in the Paris district.

The next step in the whole program will probably be the extension of electrification on the main line from Vierzon to Eguzon, Limoges and Brive. This will then make possible continuous electrical operation from Paris to Brive a distance of 313 miles.

Midi Railway

This company operates in the extreme southern part of France. Its territory makes a zone about 100 miles wide extending along the north side of the Pyrenees all the way from the Atlantic to the Mediterranean coast. At either end of the Pyrenees its lines connect France with Spain along the coastal levels. Its lines project into the mountain range in many places, but have never crossed the mountains until recently.

In 1910 the Midi Company made its first venture in electrification. A narrow-gage line in the mountains was opened between Villefranche and Bourg Madame. The 35 miles were equipped with third rail of 850 volts. This was followed by electrification of the connecting standard-gage line from Villefranche to Perpignan, about 29 miles. On this, however, high-voltage single-phase current was used—12,000 volts at 16⅔ cycles.

This latter system was then introduced on 3 more branch lines (of 16, 14 and 13 miles respectively), and an important installation commenced on the double-track main line between Bayonne and Toulouse. This section comprised about 70 miles between Pau and Montrejeau, with one branch of 22 miles. The overhead had been placed when the War stopped development. The company then possessed 72 miles of single-phase electrification in operation and a like amount partly completed. It also had a large program formulated for the future, which included development of its own power facilities.

After the decision of the Ministry in 1920, all the single-phase lines were changed to 1500-volt direct current. The power stations and transmission lines were changed to 50 cycles, and the large program of electrification fully launched. This program embraced about 2100 route miles, including about 10 per cent of new lines, and would cover about three-quarters of the company's system. At the end of 1927 about 500 miles of route were electrified. It was expected to have 625 miles done by 1929, and to proceed at the rate of about 120 miles per year.

The part of the territory chosen particularly for electrification is in general the southern edge adjoining the slope of the Pyrenees and extending up into the mountains. The first stage, which has received most attention up to now, is the west end of the system between Bordeaux and Hendaye on the west and Toulouse on the east.

Involved in the program are 2 lines piercing the mountains into Spain through long tunnels, which would hardly be practical to operate, except by electricity. These lines are the first to communicate with Spain except along the coast. They were chosen from a dozen prospective routes by the two governments as the most desirable for first undertaking. Concessions for the French part of the lines were granted to the Midi Company in 1907. One route required a new link from Pau, France, to Jaca, Spain, the other from Ax-les-Thermes, France, to Ripoll, Spain.

The line from Pau to Jaca was completed and opened with much ceremony in July, 1928. It was the good fortune of the Subcommittee to view the French section of the line only 5 months later. It is a picturesque line, displaying very difficult engineering as well as marvelous scenery. The line has steep grades, up to and exceeding 4 per cent, and many tunnels culminating in the international tunnel of Somport (5 miles long and on one of the steepest grades), which emerges into Spain at the station of Canfranc. The second line, including the long tunnels of Puymorens (in France) and of Tosas (in Spain) will probably be ready some time in 1929. It will connect Toulouse to Barcelona by a direct route.

The Midi Company uses some motor cars hauling ordinary passenger cars as trailers. The motor cars are partly rebuilt from the old single-phase cars and partly new. All the motor cars are equipped with four 750-volt motors of 175 horsepower each, giving a rating of 700 horsepower for the car. The maximum speed is 53 miles per hour. The cars have multiple-unit control, and a motor-generator set provides 120 volts for control, lighting and auxiliary power.

Most of the electrical operation is conducted with

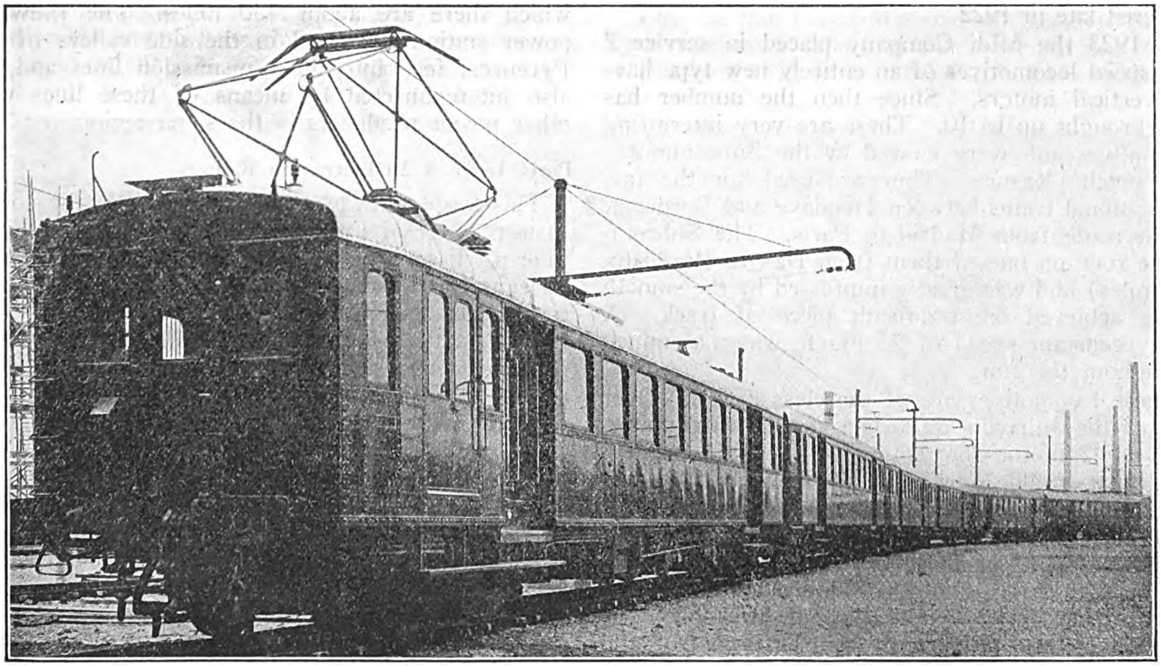

FIG. 59—PARIS-ORLEANS RAILWAY—MULTIPLE-UNIT TRAIN FOR 1500-VOLT DIRECT CURRENT.

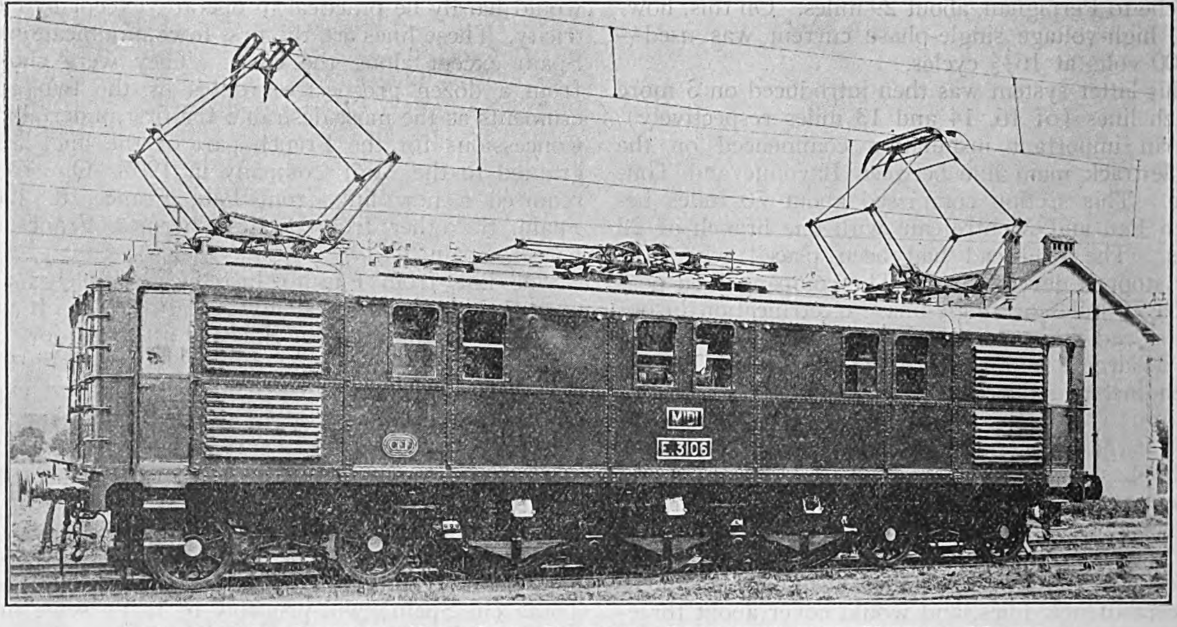

FIG. 60—MIDI RAILWAY—HIGH-SPEED PASSENGER LOCOMOTIVE WITH VERTICAL MOTORS.

locomotives. The ordinary locomotive is of type B-B and fitted with multiple-unit control. The weight is about 78 tons. The two bogies are each mounted with two 1500-volt, nose-suspended motors of 350 horsepower, making a total of 1400 horsepower per locomotive. There are 100 of these machines, the same for passenger and for freight service except for gear ratios giving maximum speeds of 56 and 37 m.p.h., respectively. A motor-generator set provides 120 volts for control, lights and auxiliary power, and there is equipment for regenerative braking. The first of these locomotives was delivered late in 1922.

In 1923 the Midi Company placed in service 2 high-speed locomotives of an entirely new type having vertical motors. Since then the number has been brought up to 10. These are very interesting locomotives and were viewed by the Subcommittee with much pleasure. They are used for the fast international trains between Hendaye and Bordeaux on the route from Madrid to Paris. The Subcommittee rode on one of them from Dax to Bordeaux (93 miles) and was greatly impressed by the smooth riding achieved on a difficult piece of track. A nearly constant speed of 75 m.p.h. was maintained throughout the run.

These locomotives are of the class 2 C 2. Over each of the 3 driving axles is a vertical twin motor, with the 2 motor shafts turning the axle through bevel gears. The motors are wound for 500 volts and have a capacity of 700 horsepower for the pair. This makes 2100 horsepower for the locomotive. The rated speed of these locomotives is 75 m.p.h., but they can safely go up to 81 miles and have been tested higher. The weight is about 115 tons. The locomotives are fitted with camshaft control and with motor-generator sets to provide 120 volts for the control, lights and small motors.

Direct current is furnished to the electrified lines of the Midi Company from 43 substations of 1000 to 4500 kw. capacity each. Most of the substations contain rotary converters, either 750-volt units in series or units wound for 1500 volts. Five of the substations have mercury arc rectifiers only. Each rectifier is composed of 2 bowls in parallel and there is a total of 16 of these groups.

There are also 10 high-tension transforming and switching stations. The substations are served by about 460 miles of 60,000-volt distributing lines, which are fed from trunk lines at 150,000 volts of which there are about 430 miles. The railway's power stations, situated in the side valleys of the Pyrenees, feed into the transmission lines and are also interconnected by means of these lines with other power producers in the same region.

Paris, Lyons & Mediterranean Railway

This large railway system operates in the southeastern sector of France from Paris to the Mediterranean. It serves a territory to the east of the Paris-Orleans and north of the Midi. It has some heavy traffic lines encumbered with steep grades and many tunnels in the southern part of the system. It also passes through a region well supplied with water power. Consequently the management has for many years had under discussion the electrification of a considerable mileage.

The double-track line from Culoz to Modane was chosen for first electrification. Starting work after the standardization in 1920, the railway opened in 1925 an experimental service on the short section between Chambery and St. Pierre d'Albigny, a distance of 15.5 miles.

The company has now in course of electrification the balance of the length between Culoz and Modane which will be done in 3 steps between 1929 and

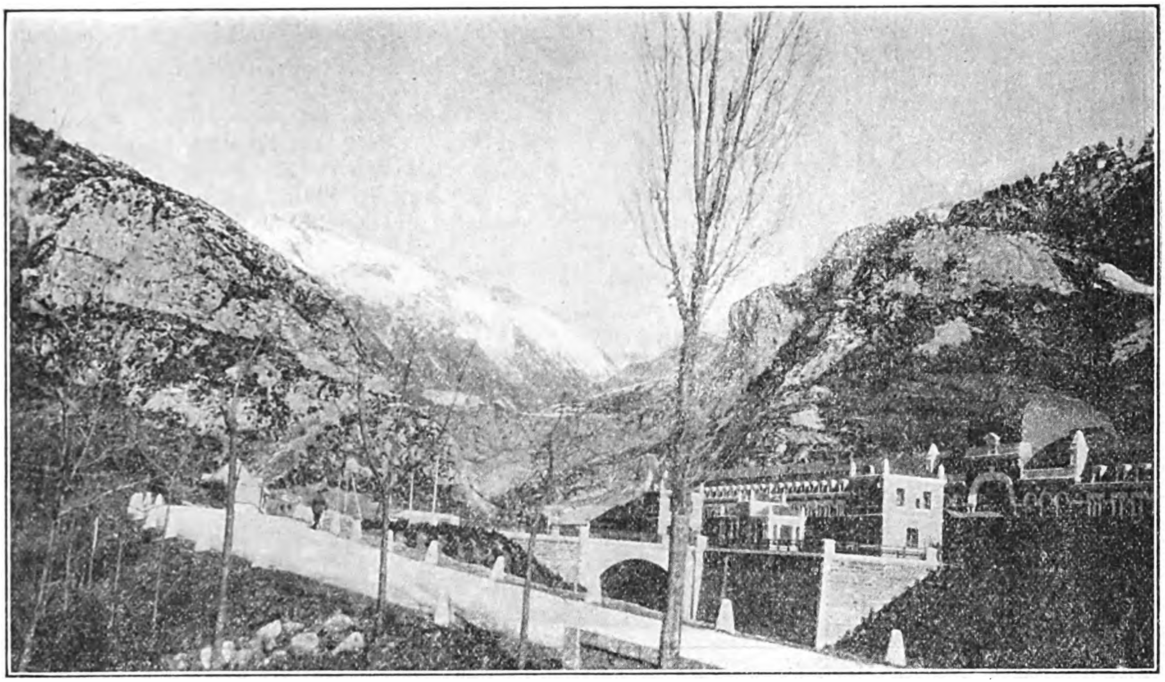

FIG. 61—Midi Railway—International Station of Canfrance, at Spanish End of Somport Tunnel, on Electrified Line Between Pau and Canfranc.

1932. There will then be 83.5 miles of double-track route, and 189 miles of all track, electrified. The line has long heavy grades, as steep as 3 per cent, and 22 tunnels. It is expected that the capacity will be greatly increased and much fuel saved.

The P. L. M. selected for its contact system a third rail at 1500 volts. This was done for several reasons, such as: ease of installation, inspection and maintenance, preventing of corrosion from passage of steam locomotives, avoidance of moving communication circuits, and avoidance of sleet troubles. It has been found that, with an overrunning rail and adjustable contact pressure, practically any desired quantity of current may be collected under any condition of the weather. The third rail is protected by insulating planks. It is carried through small local stations on the express tracks. On the ordinary tracks of the passenger stations and on the freight delivery tracks, however, an overhead contact line is substituted. All locomotives have both pantographs and third-rail shoes.

For the line Culoz-Modane, 37 locomotives have been purchased. The first ones were put into service in 1925 and 1926 with additional deliveries each year

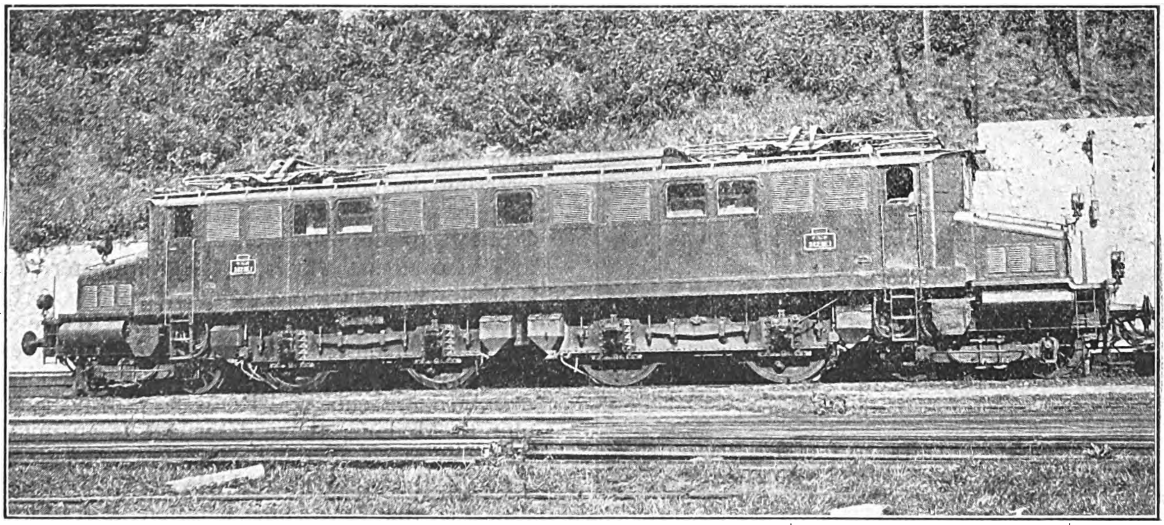

FIG. 62—Paris, Lyons & Mediterranean Railway—One Type of Passenger Locomotive for the Electrification Between Culoz and Modane.

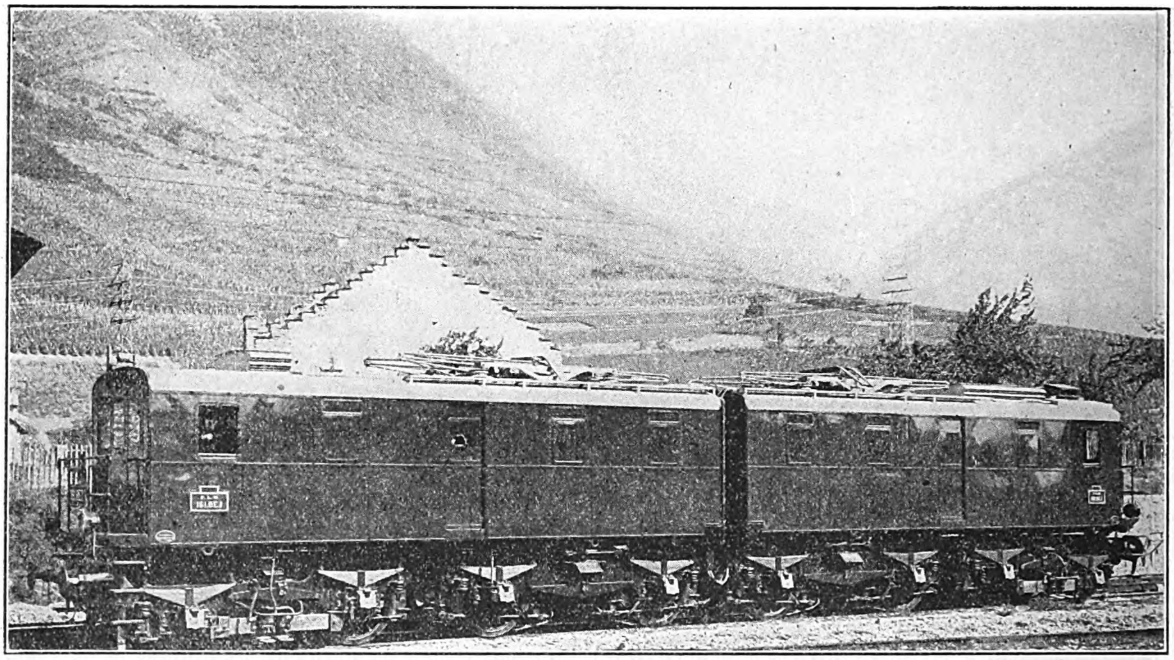

FIG. 63—PARIS, LYONS & MEDITERRANEAN RAILWAY—ONE TYPE OF FREIGHT LOCOMOTIVE FOR THE ELECTRIFICATION BETWEEN CULOZ AND MODANE.

up to 1929. All the locomotives are gear driven (with 4 or 6 driving axles), have 750-volt motors in series by pairs, and are equipped for regenerative braking.

There are three designs of passenger locomotives of class 2 B—B 2. All weigh about 140 tons, have about 2500 horsepower of motors, and a maximum speed of 68 m.p.h. A fourth type of passenger engine has recently been ordered which is called "fast express." It has 6 driving axles of the classification 2 C—C 2 and a weight of 175 tons. With 6 twin motors totaling 5400 horsepower, it is said to be the most powerful single-cab locomotive in the world. The maximum speed is 81 m.p.h. and the full rated power will be developed at 54 m.p.h. Experience with earlier designs has led the railway to favor twin motors with quill drive for its recent purchases.

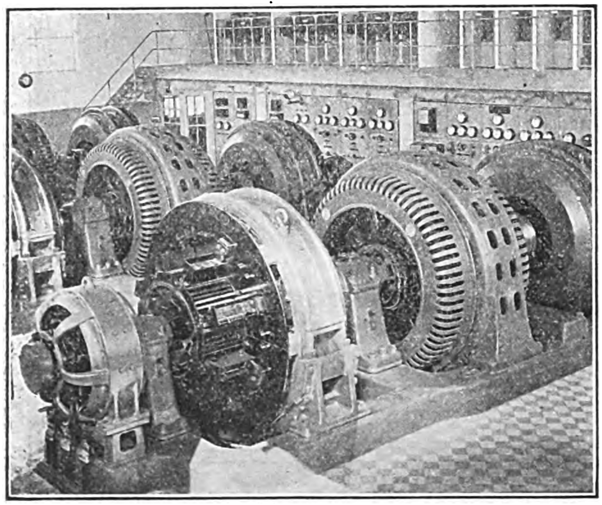

FIG. 64—PARIS, LYONS & MEDITERRANEAN RAILWAY—INTERIOR OF SUBSTATION AT ST. PIERRE D'ALBIGNY EQUIPPED WITH SYNCHRONOUS MOTOR-GENERATOR SETS.

There are also 3 designs of freight locomotives all of the same general type, 1 C + C 1. They weigh about 140 tons, and have a maximum speed of 50 m.p.h. The one-hour rating is 2400 horsepower at 21.7 m.p.h.

For power supply to the section Culoz-Modane, the railway has arranged with a large power system for delivery of high-tension energy. The railway does its own converting to direct current. Two converter substations have been in service since 1925, and 2 more will be ready in 1929. Eight will be required for the whole 83.5 miles. The general type of substation is for 3 pairs of rotaries with the capacity of 2000 kw. per pair, 2 pairs usually being sufficient for the initial installation. In one substation, however, there are 3 synchronous motor-generator sets, instead of rotaries, for the purpose of correcting the power factor.

Future plans of this company contemplate the electrification of suburban service in the vicinity of Paris, also all main lines in the southeastern section of the territory, from a point somewhat northwest of Lyons to the Mediterranean and to the Swiss and Italian frontiers. This program involves the through route from Paris to the Italian cities of Turin, Milan, Genoa and Rome, of which the section Culoz to Modane, above described, is an important part.

One of the other lines singled out for special attention is the coast line between Marseilles and Genoa, of which the section Carnoules-Nice-Ventimiglia will probably be the first step in electrification. This division of 98 miles will connect with the electrification of the Italian State Railways now in progress between Ventimiglia and Savonna (near Genoa).

The P. L. M. is also operating a short section of meter-gage railway with electric power. There are about 23 miles between the Swiss frontier and Chamonix. In the summer this line forms part of a route from Martigny (Switzerland) to Chamonix, with connections there for the rest of France. The line was built for electric operation from the beginning with 750-volt third rail. Operation of the French section is conducted successfully all winter in spite of heavy snow and sleet.

State Railways of France

This company, in addition to its distance trains, furnishes the transportation for a densely populated suburban district at the west of Paris. This suburban traffic is handled at 3 city terminal stations. As early as 1900 electric traction was adopted on one route out of the Invalides Station. In 1919 another short section was added.

The first installation in 1900 was made with electric locomotives. Motor cars were added in 1912 and 1921, and in 1922 more and heavier locomotives.

Electrification of the lines from the St. Lazare Station was taken up after the War and has progressed ever since. At the end of 1928, 6 suburban lines out of this station were electrified, and all operated with motor cars. This was the station needing the most relief from congestion. In the interest of flexibility of equipment, motor cars and trailers for this installation have been provided in sets of two coupled together, with one driver's cab at each end of the set, and automatic couplers on the cab ends of the sets. Each motor car has 4 motors of 165 horsepower. The motor cars weigh 63 tons and the trailers 41.5 tons. The seating capacity of the motor cars is 82 and of the trailers 90.

The route miles electrified out of both stations total now about 60. Two more lines are under consideration from the St. Lazare Station, one of which may be operated with locomotives using the same rolling stock as the steam trains.

The system of electrification used by this road is 650-volt third rail with U-shaped head for underrunning contact shoes. All the equipment bought since the War is, however, adapted to running on 1500 volts with the motors in series by pairs. The newer locomotives are provided with pantographs as well as contact shoes, so that they can run on the other railways if desired.

Energy is obtained from one of the local electric power companies which generates by steam. There are altogether 13 substations receiving power as 3-phase, 25-cycle. Conversion is now mostly by rotaries, but it is desired to have an installation which can be cut over from 25 cycles to the national standard of 50 cycles. Hence some mercury arc rectifiers have been installed for trial where additional converter capacity has been needed.

Other Countries

Considerable information was gathered about electrification in countries adjoining those visited. A short description of the accomplishments in Austria, Czechoslovakia and Spain is given here.

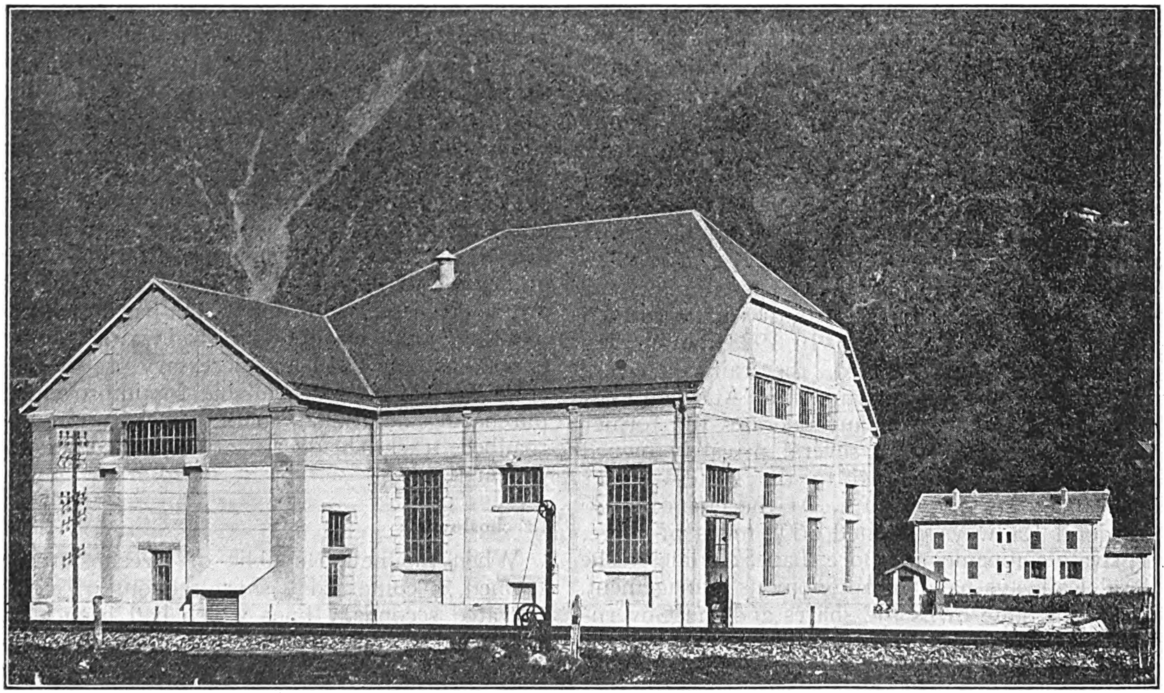

FIG. 65—PARIS, LYONS & MEDITERRANEAN RAILWAY—EXTERIOR OF SUBSTATION AT CHAMBERY.

Austria

Prior to the World War there was little railroad electrification in the Austrian State of the Austro-Hungarian Empire. Two small branches had been electrified, and 56.5 miles of narrow-gage line between St. Polten, Mariazell and Gusswerk. As for the normal-gage railroads, 2 private lines were operated by electricity—the Mittenwald Railway and the Vienna Pressburg Railway.

The Mittenwald Railway commenced operation in 1912, using electricity from the start. Although formerly a private railroad, the sections in Austria are now operated as part of the Austrian Federal Railways. There are 2 lines from Garmisch (Germany) to Innsbruck and Reutte, with the sections Scharnitz-Innsbruck and Schober-Reutte in Austria.

The Vienna Pressburg Railway operates between these two cities, paralleling the Danube, and was electrified in 1914. Pressburg is now in Czechoslovakia with a very small amount of the line likewise. The greater part of the line (between Vienna, Hainburg and the border) is now in Austria and is operated as a part of the Austrian Federal Railways.

As a result of the Treaty of Versailles, the Republic of Austria came into being as a small independent country with 33,000 square miles of area (approximately the size of the State of Indiana) and a population of 6,500,000 people. The principal source of coal passed outside the national borders into the newly created republic of Czechoslovakia.

This new country of Austria faced a series of economic problems wholly different from those its people had known before as a part of a larger and more complete economic system. Power for railroad operation was one of the problems and still continues to be after 10 years. Electrification has been made an issue of importance in the national economic program. Austria lacks a native supply of good steam coal and in addition incurs annually an unfavorable balance in international trade. As there is a great deal of potential water power, one way of improving the balance of trade seems to be electrification of railroads and consequent decrease of coal imports.

In 1920 the Austrian parliament passed an act for the electrification of definite parts of what was then the Austrian State Railways. In 1923, before this work could be accomplished, the railways were formed into a company known as the "Austrian Federal Railways." This company operates the former state-owned lines and also several privately owned lines that have been added to the system under various operating agreements. At the end of 1926 the Federal Railways operated 3608 miles of route, and private companies no more than 520 miles. The Federal Railways have an autonomous management, although the state owns the shares and the Government has supervisory powers. The policy of the Federal Railways in regard to electrification will be outlined here.

One of the first decisions was to electrify the mountain roads in the Austrian Tyrol including the principal east-to-west line from Salzburg west to the Swiss border. The purpose was to secure economies in operation of the mountain sections, to utilize water power, and to reduce the importation of coal. It was also announced that the remainder of the through east-to-west line would be electrified between Salzburg and Vienna via Linz, and the Southern line from Vienna to Gratz. This would completely electrify the principal trunk lines of the Federal Railways.

Since the formation of the Federal Railways electrification has been completed on 2 routes. The Salzkammergut line was electrified from Stainach-Irdning to Attnang-Puchheim in 1924. The Arlberg line has been changed to electric motive power as follows: Innsbruck to Bludenz in 1925, Bludenz to Feldkirch and Buchs in 1926, Feldkirch to Bregenz in 1927, Innsbruck to Worgl and Kufstein in 1927, and Worgl to Saalfelden in 1928. The 90-mile stretch between Saalfelden and Salzburg is in process of electrification and will probably be changed from steam in 1929. There will then be some 390 miles of continuous main-line electrification between Salzburg and the Swiss frontier.

The total electrified mileage of the Austrian Federal Railways at the end of 1928 was about 419 miles of line and 494 miles of main track.

In the fall of 1927 the management of the Federal Railways reconsidered the possibilities of electrification and decided to suspend work except on those sections where construction was already under way. The reason for this decision (as announced) was that operating results on the lines so far electrified did not show as much economy as had been expected. There were other reasons such as: difficulty of securing capital, need for new capital on other developments of the railways, and the fact that relations with Czechoslovakia were so good that coal could be secured cheaply and there was slight possibility of coal supplies being shut off.

The decision to suspend the electrification program called forth much adverse public criticism, also considerable opposition from the electrical equipment industries. At the present, however, there is no other course, since the electrification project was dependent on negotiation of a large foreign loan, which was for a time discussed with bankers but has now been postponed. In the meantime the railway's management is making very good and necessary use of the moderate sum of capital available for improvements by purchasing additional rolling stock, improving the roadbed, tracks, bridges, stations and other physical properties.

Czechoslovakia

When the new Republic of Czechoslovakia was formed, it contained 4 short sections of electrically operated secondary lines which had been electrified between 1903 and 1914. Three were standard-gage, totaling 34 miles, and one was narrow-gage of 22 miles in length. The voltages ranged from 550 to 1500, all direct-current.

The first electrification on the principal lines has recently been installed. After a study of several years it was decided to electrify the mid-city section of the State Railways at Prague, the capital, as part of a comprehensive plan for the development of railway facilities. The decision to electrify was largely on account of a tunnel at the south extremity of the Wilson Station or principal terminal. This tunnel is 3609 ft. in length. The relief of terminal congestion was also a factor. Coal is reasonable in price and fuel saving not the prime object in electrification.

It was especially desirable to electrify between the Wilson Station and 4 principal outlying stations where the traffic diverges. This is the present scope of the project. No decision has been reached regarding further electrification, but it is expected that electrification of some suburban lines will naturally follow. It may also be desirable to extend north from Prague to meet the German lines of Silesia which are already electrified. The intervening area is mountainous and a good prospect for electrification.

In May, 1928, electric traction was inaugurated on lines to the north of the Wilson Station, and later in the year on lines to the south. About 12 miles are electrified with an overhead line composed of 2 contact wires suspended by a catenary and messenger.

The system of electrification chosen is 1500-volt direct current. Direct current was preferred on account of taking power from the general network of 50-cycle, 3-phase lines supplying industrial and mining loads. The voltage of 1500 is considered satisfactory for both terminal and main-line electrification on account of the small size of the country and the moderate weight of the trains that will be hauled.

Electrical energy for the initial electrification is purchased from the municipal electric power system of Prague over 22,000-volt cables to the railroad substation. The substation contains 2 groups of rotary converters rated at 1000 kw. and 2000 kw. respectively. These will be supplemented by a mercury arc rectifier of 4300 kw. already ordered.

Delivery has been made of 16 electric locomotives and 2 storage-battery locomotives. All the locomotives were constructed in Czechoslovakia. There are 6 passenger locomotives of 3 types, 4 freight locomotives of one type, and 6 switching locomotives of 3 types. The battery locomotives are also for switching. All the locomotives, excepting 2 freight locomotives, have individual-axle drive.

Spain

Prior to 1928 there was not much electrification of main-line railroads in Spain. An official list of electrically operated lines names 25 sections with a total of 863 miles, but most of these are light railways or interurbans. Many of them have used electric traction from the start and are intimately connected with the urban street-car systems.

There is, however, a growing interest in electrification. One of the main-line railroads, The Northern (or El Norte), electrified a steep section of its line shortly after the War, on account of the heavy coal traffic. This was partly caused by the renewed activity in domestic coal mining as a result of embargoes on coal exports by other countries during hostilities. The increased tonnage made traffic relief imperative. Since then there have been several suburban lines electrified for reasons of traffic and economy.

Just at present there is a great deal of study being given to the general improvement of railroad service throughout the country, to the unification of gages, and to the establishment of better through lines, particularly for international traffic. Electrification is looked upon as a means for accomplishing a great deal of the desired improvement, where grades and congestion are the present difficulties, on account of its being adaptable without change in roadway and structures, or in the load gage. There is also a desire to make use as fully as possibly of the country's natural resource of water power. The government is actively cooperating in the plans and in devising means for financing the improvements which will probably have to be done by some form of subsidy or advances to the railroads. A state railway fund is already in existence.

The railroad network of Spain has been rather isolated from the rest of Europe due to two causes, the mountains and the gage. The Pyrenees form a natural barrier between Spain and France which was not overcome by railways until 1928. All railroad traffic between Spain and outside countries has been obliged to detour around the Pyrenees along the coast on either the Atlantic or the Mediterranean end of the mountains. As for the gage, the principal trunk lines of Spain use the broad gage so that passengers and freight from the standard-gage railroads of France must be transferred at the boundary.

For several years two lines have been in process of construction by tunneling the Pyrenees. The first to be completed, in July, 1928, is the line from Pau, France, to Jaca, Spain, already referred to under France. This line debouches into Spain from the long Somport tunnel at the international station in Canfranc, Spain. It is operated from Pau through the mountain section to Canfranc by the Midi Railway of France with electric locomotives of its standard types.

The second line through the Pyrenees will make a link between Ax-les-Thermes, France, and Ripoll, Spain, via the Spanish border town of Puigcerda. It will complete a through electrified route from Toulouse to Barcelona. The Spanish section has been constructed from Ripoll to Puigcerda. This part was built by the government and will be leased to the Northern Railway of Spain. The French section is to be a part of the Midi Railway. This part is scheduled for completion some time in 1929.

The first move toward the standard gage on international lines will be made in connection with the new through route from Toulouse, France, to Barcelona, Spain. This is the line just referred to as passing through Puigcerda and Ripoll. From the French border at Puigcerda as far as Ripoll this line will be converted to standard gage (4 ft. 8½ in.).

From Ripoll to Barcelona a third or parallel rail will be laid, so that cars of standard gage can travel this section as well as broad-gage cars. This will more effectively open the port of Barcelona to international traffic.

Northern Railway of Spain

In 1924 this company electrified its Pajares grade between Ujo and Busdongo, measuring 38.5 miles. This line was mentioned above in the general discussion. In 1928 they electrified the sections Barcelona-Manresa, 39.8 miles, and Barcelona-Ripoll-San Juan de las Abadesas, 65.9 miles. They are about to take over from the Government, for electric operation, the line between Ripoll and Puigcerda (at the French border), which is a part of the second international line through the Pyrenees described above.

The Northern has also in process the electrification of a section from Irun (at the French border) to Alsasua. This is a part of the present main western route between Paris and Madrid or Lisbon.

The Pajares grade was electrified with 3000-volt direct current for locomotive operation. The other lines are using 1500-volt direct current for both locomotive and multiple-unit operation. The lines running into Barcelona have multiple-unit trains for suburban service, and it is proposed to use similar equipment on the lines radiating from Madrid which are mentioned below under "Future Plans."

Madrid, Zaragossa and Alicante Railway

This is one of the 2 largest railway systems in the country having almost as many miles of line as the Northern. They have prepared specifications for electrification of suburban service out of Barcelona. It is reported that this will require 64 motor cars.

Southern Railway of Spain

The Southern Railway has a short section of line electrified between Naciemento and Gador. The length is 18.6 miles, using 3-phase current at 5500 volts. This company is a part of the Andalusian Railway which operates an extensive system in the southern part of the country.

The Catalan Railway

This is a short line of meter-gage operating in the vicinity of Barcelona. In 1926 they electrified 7.5 miles of terminal section with 1500-volt direct current for locomotive operation. This was largely on account of a tunnel.

Island of Majorca

The railway from Palma to Soller is being electrified with 1200-volt direct current. This line is about 11 miles in length.

Future Plans

Several reports have been made recommending specific lines for electrification. One published in February, 1928, listed 1306 miles of electrification as economically justified. A more recent report, in February, 1929, selects for immediate work the following sections: Madrid-Avila, Madrid-Segovia-Medina, Madrid-Villanueva de la Reina, Valencia-La Encina, Mirando-Bilbao and the Santander Line. It is expected that specifications will soon be issued for these sections as a preliminary to awarding contracts for their electrification.

Portugal

A few words may be appended about Portugal. There is no real electrification in Portugal as yet, although the electric railway between Lisbon and Cascaes is sometimes classified as electrified. This railroad is a double-track line of broad gage about 16.2 miles in length. It was, however, built about 1921 largely for resort traffic and has always used electric traction. The contact line is energized with 1500-volt direct current.

CONCLUSION

Some of the most interesting general features and developments observed in the seven countries visited will be summarized:

1. Electrification has so far been undertaken in definite localities for certain special reasons. The compelling reason is usually some condition difficult for steam operation, such as: congested traffic, suburban service in the neighborhood of large cities, heavy grades, long tunnels, or the absence of good steam coal. In the latter case the existence of water power has an important influence on the course followed.

2. Electrification will be extended where it now exists, and introduced into new districts, for the same compelling reasons. There is not at present any general tendency toward complete electrification of railroads in any of the countries.*

3. Most of the electrification in Europe has come into existence since the War. There were only a few miles in any country prior to 1915, and most of the development has been realized since 1922. Much experimental work on electrification, however, had been done between 1900 and 1914. The more rapid progress in recent years has benefited by the earlier research.

4. The establishment of large commercial power systems (both private and state owned) in Europe has also been a post-War development, followed by interconnection of power systems so as to provide large pools of power. This has made electric power more generally accessible to the railroads, enabling them (1) to utilize the energy with a minimum of investment for transmission lines, (2) to reinforce their own power systems by interconnection with the commercial power systems, and (3) to trade surplus energy both ways with the commercial power systems.

5. Recognition of the technical advantages of securing power from the large commercial networks seems quite general and constantly increasing in effect. Even where the railroad has established its own power stations there is usually some form of interconnection with the industrial power systems.

---

* Switzerland has more electrification and a higher percentage of lines electrified than any of the other countries, but the country is small and the railway lines throughout have nearly the same topographic and economic problems. Even here they do not anticipate complete electrification.

APPRECIATION

This report would not be complete without a tribute to the unfailing courtesy and hospitality accorded the Subcommittee in all countries visited. The most cordial cooperation in the objects of the trip was given by railways, underground railways, electrical manufacturers, sales representatives, power systems, and consulting engineers. Many valuable contacts were established which it will be the pleasure of the Subcommittee to maintain for the benefit of the general Committee in future years.

Several delegations of European railway engineers have already visited the United States and more are planning to come within the next few years. This it is hoped will give the Electrification of Steam Railroads Committee some opportunity to repay the many favors extended to its representatives on their visit to Europe.

Thanks are also gratefully extended to the members of the general Committee and to other friends who assisted in planning this inspection trip, also to all those who provided the Subcommittee with introductions to European engineers and executives or who otherwise contributed to the success of this investigation.

APPENDIX B

REPORT OF SUBCOMMITTEE ON FORM OF CONTRACT

Foreword

Anyone examining the following analysis of 15 contracts covering power supply for railroad electrifications in the United States will probably be impressed with the fact that there is considerable variation in the terms and conditions of these contracts, and, if each of these contracts could be examined, the necessity for clarity of expression would immediately be the outstanding thought.

With the great diversity of conditions as to railroad requirements and central station supply, it is not surprising that variations should appear, particularly in the older contracts. Nevertheless, it seems to the Subcommittee that it will be possible in the future to greatly simplify and standardize the terms and conditions. It is recommended that the problem be approached with a broad point of view, knowing that in the long run difficult terms, and conditions that are only irritating, will be either ignored or modified.

Statement of the Problem

Electrification of steam railroads has advanced to the point where there is a great deal of accumulated experience to guide the future progress. If this information can be gathered into one place it will have great value. One of the important points on which much remains to be done is the matter of contractual relations between railway and power companies. The study embodied in this report was undertaken with the purpose of submitting to the power industry and the railroads a uniform basis for such contractual relations in event of the extension of electrification into new places.

As the electrified zones expand and spread into the territories of additional power companies there will be a distinct advantage in having similar agreements, similar contracts and relationships, and, in a word, analogous operating conditions in adjacent portions of the railway systems. Without doubt the power companies may find it advisable, or even necessary, to interchange energy for railroad purposes, or, as it might be expressed, to pool their facilities along extensive electrifications. This, then, will require a certain similarity of contractual relations.

It should be plainly stated that the price paid for energy is only one feature of the contract, although admittedly of utmost importance. The contract form can be discussed and planned quite independent of the price. In fact, a properly designed contract form may be used in one part of the country with certain prices inserted in the rate section, and may be used elsewhere with other prices inserted in the rate section to meet different conditions in the cost of producing or supplying electrical energy. In the interest of standardization, however, the rate form, like the remainder of the contract, should be shaped to a standard expression requiring only the substitution of proper, adequate prices depending upon local conditions.

When general acceptance is accorded by both railway and power industries to the principle of standardizing, so far as possible, the terms and conditions of large power contracts, it is the opinion of this Subcommittee that a great deal will have been accomplished toward better mutual understanding.* It is not the expectation of this Subcommittee that at this time one standard form and phraseology can be submitted by a small group of men that will satisfy all the requirements of every situation. There are, however, certain basic features of contract designing, certain inherent features of the power business, and other inherent features of the railway business that are fairly universal and well-known. These should be recognized in any contract, and then should be supplemented (but, if possible, not altered) by such provisions as adapt the whole to the specific locality where the contract will be applied.

The Subcommittee has thus for this year's work adopted the plan of presenting an outline of all the desiderata for inclusion in a well-rounded contract. The outline which concludes this report is intended to cover all the conditions which are likely to arise in connection with electricity supply for traction and for other railroad service along the right-of-way. This proposed form of headlines, or titles, can probably be simplified in many cases, but it is submitted as something to which both railroads and central stations may refer when negotiations are opened between them in any part of the country.

---

*As an indication of the attitude of the railroads toward this matter, it may be stated that associations of railway engineers and executives are now engaged in studying the essentials of a standard power contract.

Analysis of Contracts

For the purpose of analysis the Subcommittee collected 15 actual, existing contracts covering supply of energy to 13 railroads for their electrified sections. The contracts date from 1912 to 1929, and all are in effect at the present time.

These contracts come from widely scattered parts of the country and include supply from both water-power and steam-power companies. They are probably quite representative, as they include most of the power sales for electrification, excepting sales from one railroad to another. In size, the contracts vary from a few hundred kilowatts up to 25,000 kw. or more.

As a class, they are rather special, and contain many provisions not used in ordinary power contracts. They are also quite varied among themselves, the only similarity of form or expression being in cases where contracts have been executed by related power companies.

Several of the contracts were furnished with the comment that they were special and not generally applicable. This proved to be true, and one was in such unusual form that comparison with the others was not practicable. Hence it was dropped from consideration and an analysis made of the remaining 14 contracts.

All of these contracts contain some special or unusual conditions except three that conform to regular contracts given to large industrial power users. All of them, in spite of their variations and differences of viewpoint, present interesting and valuable features which may be incorporated into a standard form of contract of much more general applicability.

The contracts analyzed are so at variance in arrangement and in content that it is almost impossible to get them into shape so that direct comparison can be made. This immediately shows the difficulty faced by railroad and power company officials in trying to ascertain what is good practice in designing a power contract.

The most essential features of the fourteen contracts are as follows:

Term

Varying from 3 to 99 years.

10 years most frequent (6 cases).

Longest in connection with water-power companies (30-99 years).

Renewal

Mostly renewable except those for long periods.

Six are indefinitely or perpetually renewable by terms of one to five years each.

When renewable, usually require 12 to 24-month notice of intention to terminate, although two small ones do not require more than 30 days.

Increase of Capacity

Capacity where not definitely limited may usually be increased on 12-month notice during early years of contract, or later in term if renewal or extension is agreed.

Place of Delivery

9 at railroad substations.
3 at power-company generating stations.
2 at power-company substations.

Form of Energy

8 contracts for 3-phase energy at 60 cycles and voltages from 11,000 to 100,000.
4 contracts for 3-phase energy at 25 cycles and 11,000 or 13,000 volts (one also includes single-phase energy).
1 contract for 1500-volt direct current.

Metering

Considerable uniformity in provisions for metering, similar to the usual contracts for large industrial power customers.

Unbalance

Usually not stated.

One contract limits to 100 kv-a. and one limits to 10 per cent.

Strike, Riot, Fire, Explosion, or Act of the Elements

Calamity due to causes not controllable by either party is variously treated.

Some contracts allow relief to one party only, and some to both. Individual provisions are as follows:

a. Omit all periods of one week or longer.
b. Omit all days affected.
c. Omit all periods but extend term of contract accordingly.

Demand charges and guarantees are usually suspended and the railroad pays an Energy Charge alone during the continuance of calamity.

Interruption of Supply

The companies usually covenant to use diligence in preventing interruption.

Few provide any penalty or means of securing compliance except through power of cancellation as mentioned below.

One provides a cash rebate for long interruptions (over 15 min. per day) and another provides for adjustment of demand and guarantee.

Arbitration

Eight contracts provide for arbitration by a board of three. The provisions in regard to arbitration are quite similar. Some add right of cancellation if loser refuses to accept decision.

Regeneration

Two contracts provide that surplus energy from regenerative braking shall be absorbed by the power company and deducted from the kw-hr. supplied.

Change of Rate

Four contracts protect the railroad against lower rates to other customers for similar service. Five provide for rates to increase or decrease subject to public service commission or state authority. (In one of the latter, railroad may withdraw if rate is increased.) In one contract a reduction of rate is provided in case of certain growth of the railroad's electrical requirements.

Form of Rate

Ten contracts have Hopkinson (or two charge) form. Four are straight-line rates. Of the ten Hopkinson rates, two are the simplest form with single Demand and Energy Charges. Eight have the Demand and Energy Charges (either or both) in blocks, and two of the eight use the Wright (or load-factor) principle in blocking the Energy Charge.

Two of the straight-line rates involve measurements of demand, as one adjusts the rate according to load factor and the other adjusts the guaranteed consumption. The two remaining straight-line rates base the guaranteed consumption on the contract capacity.

Demand Interval

Twelve contracts require the measurement of demand, daily or monthly. Seven use a 60-minute (sometimes clock-hour) period, two use 30 minutes and three use 5 minutes. Several specify that no demand registered immediately after an interruption of service shall be considered in billing.

The Billing Demand

In case of the 60-minute demands, two use the one highest only, three make an average of three demands, one makes an average of six and one averages all the daily demands in the month.

In case of the 30-minute demands, one uses the single highest of the month and the other makes an average of twenty demands.

In case of the 5-minute demands, two use an average of three and one uses an average of all the daily demands in the month.

Period to Which the Billing Demand Applies

Seven contracts use the actual measured or calculated demand each month. Three of these do not allow the billing demand to recede below a certain quantity, either 70 per cent of its highest value in the previous 12 months, or 75 per cent of the highest value attained during the previous life of the contract.

Four contracts make each successive highest monthly demand effective for billing during twelve months, and one retains the highest monthly demand for the remaining life of the contract.

Minimum Charge or Bill

Most of the contracts start with a fixed amount based on demand or consumption or both, followed by increases based on actual use.

The ten contracts with rates of Hopkinson form base the continuing minimum charge as follows: Two on a specified number of kilowatts, two on the established demand, four on the established demand and a guaranteed load factor, one on the miles of line electrified.

The four contracts with straight-line rates base the minimum charge as follows: Three on guaranteed capacity factor, and one on demand plus a guaranteed load factor.

Emergency Demand or Energy

Eight contracts provide for excess service on account of extraordinary operating conditions, usually subject to power company's ability to supply the excess and specifying some previous notice. Three specify the length of time during which excess power may be taken, varying from 24 hours to one week. Two limit the occurrence to three times per year. One limits the taking to double the established demand. During periods of excess demand the guarantees are usually waived and ordinary Energy Charge prevails.

Power Factor

Eight contracts provide that the power factor (particularly at times of heaviest demand) shall not go below certain standards as follows: One limits to 75 per cent, three to 80 per cent, three to 90 per cent and one to 95 per cent. Four of the eight impose penalties for low power factor by correcting the demand proportionately.

Fuel Clause

Ten contracts provide for adjustment of the rate according to the cost of coal, usually by adjustment of the Energy Charge. There are five general types of this adjustment: One contract adjusts monthly according to the cost per B.t.u., five adjust monthly according to the cost per ton, two adjust quarterly according to the cost per B.t.u., one adjusts quarterly according to the cost per ton, and one adjusts annually according to the cost per B.t.u.

Limitation of Demand

One contract provides for limitation by automatic switches, two by power company attendants subject to instructions from railroad.

Cancellation

Eight contracts provide cancellation as a penalty for non-performance. In one case the power company may cancel for default in payment, in four cases the railroad may cancel on account of poor service and in three cases either party may cancel for the respective reasons just stated.

Special Provisions

There are many special provisions of interest. Those that appear most important, selected from the various contracts, are as follows:

1. Power company assumes operation of railway's generating station with option to purchase.
2. Railway may enter and operate power company's generating station in case of necessity.
3. Provisions for placing liability on respective companies in case of accident.
4. Space for substations and transmission lines provided free by railroad (or at nominal rental). Power company may use such space for any purpose incidental to its business, either without charge or with charge based on proportion of non-railway business.
5. On expiration of contract railroad shall purchase equipment installed for its exclusive use by power company and not over fifteen years old.
6. Railroad may terminate contract by purchasing power company's special facilities for its particular service.
7. Power company may rent space for communication circuits on railroad's pole lines.
8. Either party may install equipment in station or substation belonging to the other.
9. Either party at manually operated station or substation will operate equipment of the other without labor charge.
10. Power company will maintain electrical equipment, and transmission or distribution lines, of railroad company, at cost.
11. Railroad may use energy for all purposes incidental to its business and supply these needs at various locations by its own transmission or distribution lines.
12. Railroad may supply energy to subsidiary and related companies.
13. Railroad may supply energy to other railroads for train operation when such operation is conducted electrically over the first road.
14. In event that railroad company extends its electrification into the territory of another power company, the first power company agrees to make a reciprocal contract, with the second power company, for emergency transfer of energy.

Form of Contract

The contract should be as brief and concise as the circumstances permit. On the other hand, no essential provisions should be omitted. For the sake of uniformity all contracts for railroad electrification should be drawn in substantially similar form, using the clauses and provisions that suit the case. The following outline has been drawn to indicate the essential elements to be incorporated in all contracts—it being recognized that in most cases not all of the items will be required, while in certain cases other special provisions to meet local conditions may be necessary.

The general subjects to be provided for in any contract are as follows:

Preamble
I. Term of Contract
II. Quantity and Scope
III. Form of Delivered Power
IV. Points of Delivery
V. Rates
VI. Metering
VII. Determination of Quantities Used in Billing.
VIII. Bills, Payments and Penalties for Non-payment
IX. Special Facilities
X. Operating Arrangements
XI. Protection Against Damages and Claims
XII. Definitions and Units
XIII. Sundry Provisions
XIV. No Discrimination in Rates
XV. Arbitration
XVI. Amendments
XVII. Successors and Assigns.

These general subjects should be elaborated substantially as set out on the remaining pages.

Preamble

a. General conditions
b. General location
c. General purpose.

I—Term of Contract

a. Original term
b. Extensions
c. Renewals, automatic or otherwise
d. Commencement of term
e. Supply of energy during preliminary period.

NOTE: The percentages and quantities stated in various places in this outline are not suggested as universally applicable, but are used only to make the text readily understandable.

II—Quantity and Scope

a. Initial quantity
b. Increase or decrease in quantity
c. Ultimate quantity for which provision is made
d. Notice, time interval and conditions for change in quantity
e. Extent of territory included.

NOTE: See note at end of VII.

III—Form of Delivered Power

a. Principal supply (for traction purposes). Volts, frequency, phases, etc., and allowable variations
b. Secondary supply (for traction purposes)
c. Auxiliary supply (for miscellaneous lighting and power of stations, shops, yards, signal service, etc.).

NOTE: III and IV may be combined if simplification may thereby be accomplished or understanding improved.

IV—Points of Delivery

a. Initial points of delivery
b. Additional or subsequent points of delivery and conditions of establishing them
c. Points of delivery for purposes other than traction.

NOTE: In each case specify the method of connection and the ownership of facilities.

V—Rates

a. Scale of charges
Primary charge (based on demand)
Secondary charge (based on energy used)
b. The guaranteed payment
(Minimum of demand, or demand and energy together, for which payment shall be made. Including provisions for maintaining a definite load factor, if any)
c. Fuel clause
Provision for adjusting the charges according to the cost of fuel, preferably according to the cost per B.t.u. This adjustment may be billed as a separate item each month, and changed yearly or quarterly on the basis of average actual cost of fuel at all applicable stations of the power company.

NOTE: It is suggested that the scale of charges be of the Hopkinson (or two-part) form of rate, blocked in both parts to allow for growth of the business.

VI—Metering

a. Power company to furnish, maintain and read meters
b. Location of meters
c. Railroad to provide space for metering (where necessary)
d. Meters to measure demand, energy used, power factor, regenerated power returned to power company, etc.
e. Standards of accuracy
f. Standards for testing
g. Representatives of both parties may be present at all readings and tests
h. Meters to be tested periodically [e.g., 3 months, 1 year, etc.]
i. Meters to be given special test at any time on request of either party
j. Payment for special test
k. Refund or payment as result of any test [not retroactive more than one month or prior to last test]
l. If meter fails to operate, payment at average rate of other days in same month (or other equitable basis).

VII—Determination of Quantities Used in Billing

a. The demand interval to be a specified number of minutes, may be the clock hour or some certain part thereof.
b. No demand reading or interval, or any part thereof, to be taken within [one hour] of resuming operations after an interruption of service.
c. The maximum demand for the month to be determined by: (1) averaging certain daily (or other periodic) maximum demands at each point of delivery, and adding together the resultant demands for the different points; or (2) computing the simultaneous daily (or other periodic) maximum demands, for all points of delivery together, and averaging certain of the simultaneous demands; or (3) a combination of the two for principal supply and auxiliary supply.
d. The monthly demand so computed to be adjusted for lagging power factor (when the average power factor is less than [80] per cent, or when the power factor at time of maximum demand is less than [90] per cent).
e. The monthly demand so computed to be corrected for unbalance of three-phase power [when over a certain percentage, probably 10 per cent].
f. The result of items "c, d, and e," inclusive, to be the monthly maximum demand used for billing, provided it be not less than the established demand or such other amount as may be fixed by the contract.
g. The established demand to be the highest monthly maximum demand (or a percentage thereof) recorded either (1) within the previous twelve months or (2) within the life of the contract.
h. The demand may be determined yearly at the end of the year, and an adjustment made to correct the charges and payments of the 12-month period.
i. Consumption of energy for billing purposes to be the sum of consumptions at all separate points of delivery after deducting the surplus energy returned by the railroad. This surplus is the energy produced by regenerative braking, which is not absorbed in the railroad's own business.

NOTE: If desired to limit the increase (or rate of increase) of demand on the power company's facilities, provision should be made here or in II for gradual growth of demand [say 10 per cent per annum] unless formal request is made for additional capacity. The same applies to permanent decrease in demand and capacity.

VIII—Bills, Payments, and Penalties for Non-Payment

a. Period covered by bill (and pro-rating of annual charges if any)
b. Date of rendering bill
c. Date for payment of bill
d. Interest for delay in payment
e. Discontinuance of service for non-payment (and charges which continue)
f. Reinstatement of service, with conditions
g. Cancellation of contract for non-payment
h. Estimates used in billing and adjustments at later dates (in case demand, fuel charge, etc., are adjusted at end of quarter or of year).

NOTE: The provisions for arbitration, stated elsewhere, to include provisions for continuance of service and payments during adjudication of dispute.

IX—Special Facilities

a. Power company to extend its facilities to certain places at its expense.

b. Railroad to extend its facilities to certain places at its expense.

c. One party may construct or extend facilities for the other at cost, or agreed price.

d. Either party may build substation on the other's property, or install equipment in the other's station or substation at nominal rental. If such privilege is used in part for other purposes not involved in fulfillment of this contract, a reasonable rental to be charged for the proportionate part of the space.

e. Either party may rent space for communication or control circuits on poles or structures of the other.

f. Contract may provide for communication or control circuits to be installed jointly between places involved.

g. All high-tension power and transmission equipment (or supply system) to conform to standards and practice of power company.

h. All low-tension power and transmission equipment (or utilization system) to conform to standards and practice of railroad company.

i. All engineering and construction plans to be jointly approved by representatives chosen by corporate officials of each party and recorded with the other.

j. Synchronous machines to be usable for power-factor correction.

k. Voltage regulators of field-control type, induction regulators, other types of voltage regulators, or other regulating devices or relays, to be supplied by either party on its own equipment (as needs justify) to maintain quality of service or to enable synchronous machines to operate in step.

l. Power company to promote continuity of service by: (1) furnishing loop or duplicate circuits (from separate sources, if possible), or (2) paralleling railroad with a transmission line, or (3) maintaining interchange connection and agreement with other power companies.

m. At termination of contract, substation buildings to be purchased by owner of land at fair value.

n. At termination of contract, railroad to purchase substation or conversion equipment installed within last [x] years especially for fulfillment of this contract and not desired by the power company for its other business.

o. At termination of contract, railroad to purchase all special facilities of power company (aside from buildings) installed on the railroad's premises for exclusive purpose of serving the railroad within the last [x] years, and not desired by the power company for its other business, at fair value.

p. At termination of contract, power company to purchase all special facilities of railroad company installed on power company's premises and desired by it for its other business, at fair value.

q. At termination of contract, access to be given by either party to the other for removal of equipment from premises, such removal to be accomplished within a specified time.

NOTE: Consideration should be given to the problem of inductive interference whenever this problem necessarily becomes a part of the contractual relations between the two companies.

NOTE: Items "m" to "q," inclusive, may be placed in separate article entitled "Conditions at Termination of Contract."

X—Operating Arrangements

a. Continuity of service essential to mutual satisfaction. Each party to covenant to use diligence in maintaining continuity and in reestablishing service after interruption.

b. In case of interruption of either supply or utilization, a permanent record to be kept by each party, showing time, duration and cause

c. Emergencies beyond control to absolve either party from duty to supply or to receive power. Rate suspended during such period. Such emergencies are: strike, fire, explosion, insurrection, riot, invasion by the public enemy, action of the elements, etc.

d. If intervention by federal or by state government renders compliance with contract temporarily or permanently impossible, the contract may be suspended or terminated without cause for liability or damage, but power company (being enjoined or prevented) to continue service with consent of authorities until other supply can be provided by railroad.

e. During abnormal operating conditions on the railroad, the power company to furnish excess demand (or capacity) and energy, if it has sufficient available capacity, up to [x] per cent in excess of normal (or established) demand. Notice of abnormal operating conditions to be given by railroad to power company with estimate of duration, and when foreseen sufficiently in advance to be given in writing. Such conditions to include abnormal traffic and abnormally low temperature. If power company cannot supply excess demand fully or at all parts of the day, railroad to so arrange its business as to cooperate with power company in using available capacity to the best advantage of both parties. The regular demand charges to be paid for excess demand during months (or days) when used. All emergency energy to be paid for at regular energy charge.

f. Operation of railroad company's generating station may be permitted in parallel with power company's stations.

g. In case railroad continues to operate its own generating station (whether in parallel with power company or otherwise), railroad not entitled to excess demand or energy due to failure of its own power facilities as an abnormal operating condition, unless the four following conditions are fulfilled with regard to railroad's generating station and other power system or equipment: (1) Capacity must be adequate for load which is normally required to be carried, (2) Reserve must be adequate for carrying load during repairs or renewals, (3) Maintenance of facilities must be reasonably good, and (4) Power company specialists in generation and distribution must be permitted to make periodic inspection of railroad's generating station and other power facilities (and records thereof) for purpose of certifying to the first three items just enumerated.

h. Interruptions not due to emergencies (above described) and including operating contingencies of power company's system or equipment (or of railroad company's equipment maintained by the power company) and including cessation or curtailment of service for repairs or renewals by power company, to entitle railroad to rebate on demand charge, if of sufficient duration. All interruptions of [15] minutes or longer to be rebated for monthly (or yearly in case of yearly demand charge) at agreed rate in relation to the actual average demand charge of the period and in proportion to the total length of the interruptions.

i. Provision for joint power control, or power supervision. Representatives may be stationed in each other's offices or power departments. Orders may be given by power supervisors of one company to employes of the other for control of power supply.

j. Either company, at manually operated station or substation, to operate equipment of the other, subject to its orders.

k. Demand may be limited by control devices or by manual operators acting according to instructions of railway company.

l. Provisions for inspection, maintenance and renewal of special facilities or joint equipment, specifying by whom and at whose expense.

m. If contract is terminated before expiration of term, for any reason except non-payment, the power company to continue service until railroad can make effective another source of supply.

XI—Protection Against Damage and Claims

a. Railroad to protect power company from damage to property and to employes from faulty electrical equipment or operation of railroad.

b. Power company conversely to protect railroad company.

c. Power company assumes liability in respect to injury of its employes while working on railroad's premises except as covered by (a).

d. Railroad to protect power company against claims for damage to outside persons or property of others due to faulty electrical equipment or operation of railroad.

e. Power company conversely to protect railroad.

f. Railroad to use due diligence in operating and maintaining its system so as to take and use electrical energy regularly. No claim for damage on part of power company for failure to use energy, the charges for readiness to supply being included in the rate.

g. Power company to use due diligence in operating and maintaining its system to preclude interruption of service to railroad. No claim for damages on part of railway not covered (1) by provisions for waiver or reduction of primary charge during periods of interruption, or (2) by right of cancellation in event of continual interruptions or poor service.

XII—Definitions and Units

a. Preliminary period
b. Installed capacity (of equipment allocated to this contract)
c. Power (kilowatts or horsepower, as required)
d. Energy (kilowatt-hours)
e. British thermal units
f. Demand and maximum demand
g. Consumption
h. Load factor (or capacity factor as required)
i. Power factor and kilovolt-amperes.
j. Day
k. Clock hour
l. Abnormal demand
m. Abnormal hour, day, or period
n. Abnormally heavy railroad traffic
o. Abnormally low temperature
p. Other units and terms as defined at date of this contract by American Institute of Electrical Engineers (or American Standards Association).

XIII—Sundry Provisions

a. Waiver of rights not to estop action in case of subsequent defaults.

b. Railroad to have preferential right to use power as far as legal and justifiable.

c. Operating orders required to be given by an official or supervisor of one party to the other to be given in usual form, oral or written, used by the former for transmitting similar orders to its own employes for similar duties.

d. Energy may be used by railroad for any purpose incidental to its business, also by subsidiary and related companies.

e. Energy not to be resold for general lighting or power purposes or to industrial customers.

f. Energy may be used by trains of other railroads having operating rights over railroad company's electrified tracks.

g. Power company to have access to railroad premises for all purposes in connection with rendering of proper service, care of its property, and reading meters.

h. Each company to have access to other's books, records, and accounts for all purposes concerning: testing of switches, meters and equipment; cost of coal, etc. The same access to be granted to arbitrators in case of arbitration.

i. Statements of demand, consumption, voltage, frequency, irregularities, interruptions of supply or use, as the case may be, may be required daily or periodically by either party.

j. Power company may make contingent contract to operate, lease, and/or purchase railroad's generating station.
k. Energy supplied by power company to be generated by it at its own stations or procured by it from any other reliable source.
l. In event that railroad company extends its electrification into the territory of another power company, the first power company to agree, subject to approval of railroad, (1) to endeavor to make a reciprocal contract with the second power company (or companies) for emergency transfer of energy, or (2) to endeavor to make a sub-contract with the second company for additional supply of energy to the railroad by the second company.
m. Notices under the contract given by either party to be in writing and to be delivered, or sent by registered mail, to designated officials of the other party.

XIV—No Discrimination in Rates

a. Railroad to receive as low rates as any other customer purchasing similar service.
b. Rates subject to control by state public service commission.
c. Railroad may cancel contract within certain period, in event that public service commission orders increase of rate, provided that railroad can secure power elsewhere at a lower cost.

XV—Arbitration

a. Provided for all disputes under the contract
b. Selection of arbitrators
c. Operation to continue during arbitration
d. If dispute relates to amount of charges, two alternatives suggested: (1) Approximate payments to be deposited pending settlement, such payments to be average of three monthly payments made under the contract prior to dispute, or (2) Railroad to pay bills rendered without prejudice to its right to recover back any sum which the arbitrators shall find to be overpayment with interest thereon at rate of [x] per cent.
e. Time, place and notice of arbitration, and duties of arbitrators
f. Rendering of decision
g. Effect of decision
h. Payment of arbitrators.

XVI—Amendments

a. Contract includes all terms and provisions
b. Amendments to be made only by supplemental instruments of equal legality executed by corporate officials.

XVII—Successors and Assigns

a. Contract in duplicate
b. Contract binding upon successors or assigns
c. Conditions governing assignment by either party.

APPENDIX C

STATEMENTS OF RAILROAD PRESIDENTS

PART I

ELECTRIFICATION OF THE PENNSYLVANIA RAILROAD

Announcement by W. W. ATTERBURY, *President, on Oct.* 31, 1928

The Board of Directors of the Pennsylvania Railroad Company has authorized the electrification of the entire road train service, freight and passenger, between New York and Wilmington, Del.

This authority covers a part of a plan which includes also electrification of the grades between the Susquehanna, Schuylkill and Delaware River valleys and our eastern terminals.

The project as now announced covers the passenger and freight service on 325 miles of line and 1300 miles of track, beginning at Hell Gate Bridge, New York, where connection is made with New England, and extending west and south to Wilmington, west from Philadelphia on the Main Line in the direction of Harrisburg as far as Atglen, Pa., and the low-grade freight lines which join at Columbia, Pa., and connect the cities of New York, Philadelphia and Wilmington with the West.

This electrification will far exceed in magnitude and in importance that of any other railroad in the world, in miles of track to be electrified, in volume and density of passenger and freight business handled, in size and amount of equipment required, in the number of trains affected, and in terminal operations involved. The project will be undertaken progressively in sections and extend over a period of years.

It is estimated that the cost of this electrification will be approximately $100,000,000, to be spent, however, during the next seven or eight years at the rate of about $15,000,000 per year; 60 per cent of the total being for catenary, transmission line and substation construction, and 40 per cent for rolling stock. This will be a normal percentage of Pennsylvania Railroad improvement expenditures, which have been averaging $70,000,000 a year; a reasonable portion of which has always been provided out of surplus earnings. These proposed capital expenditures for electrification will make unnecessary certain other capital expenditures on this section of the railroad which would have to be made unless electrification is carried out.

The authorization of the Board of Directors to inaugurate this work follows exhaustive studies of the whole industrial and transportation situations in the eastern part of the country, including the terminal developments already under way or projected for Philadelphia and Newark. While this analysis was worked out in detail on the basis of the traffic estimated for the year 1935, the probability was not lost sight of that by 1950 the metropolitan area around New York would extend to New Brunswick on the west and well out on Long Island on the east and contain 30,000,000 people, and that there would be similar development in other cities.

The system adopted will be such that it will, by the simple addition of increased power and increased rolling stock, handle a movement of any magnitude which it is possible to handle over the existing tracks and at such speed, within the bounds necessary for safe operation, as the demands of the traffic may require from time to time.

Reasons for Electrification

The immediate factors which influenced the decision to proceed with electrification at this time were as follows:

1. The greater economy of electric traction as compared to steam operation in dense traffic territories;

2. The growth of the southern passenger business;

3. The increasing density of both freight and passenger business on our eastern lines and the probability that in the future more rapid movement would be required;

4. The desirability of utilizing the advantages of electric traction in connection with the construction of our new passenger terminals at Philadelphia and Newark;

5. The desirability of building a locomotive that would meet the requirements from the standpoint of weight of train, speed, and reliability that we believe will have to be met in this territory in the next twenty years;

6. The probability that the project, if started now, could be completed with a less total expenditure, all matters considered, than if started at a later date.

Among the more important details of construction and operation which are involved in this project are the following, which are of possible interest to the public:

Locomotives and Motor Cars

We intend to use the alternating-current single-phase system of electric traction, similar to that now in use in our Philadelphia suburban service, because we believe it the best adapted for heavy-traction trunk-line service. Our engineers studied this system abroad a number of years ago, and in anticipation of the future we have been working on its development ever since. It is now used extensively in Germany, Switzerland and Sweden, and in this country on the New Haven, Norfolk & Western, and Virginian Railways.

In suburban service we will use multiple-unit cars similar to those in the subways of New York and Philadelphia and those at present in use on our Philadelphia suburban lines, because they are more desirable from the standpoint of rapid transit on runs where frequent stops must be made.

The through freight and passenger service will be handled by electric locomotives because they handle that kind of service best.

With the assistance of the electric companies we have developed three types of electric locomotives which when used singly or in multiples as required will provide any power demanded by size, weight of trains, or speed. They are so designed as to permit the maximum interchangeability of parts, the minimum cost of maintenance, and the simplest and most direct methods of manufacture.

By the method of operation proposed we expect eventually to reduce the number of freight trains 50 per cent for a given car movement and increase the speed to any reasonable extent required. This of itself provides for a 100 per cent increase in capacity in so far as freight movement is concerned.

In the case of passenger trains, we expect to eliminate all double heading and most, if not all, of the second sections of trains and avoid the possibility of rough handling due to limited starting capacity, all of which make for greater comfort, better service, and increased capacity of the line.

The rest of the details are relatively minor and, while they have been fully worked out, are more or less subject to change dependent on the developments of the art between now and the time each expenditure is made.

Principal Facts About Pennsylvania Railroad Electrification Between New York and Wilmington, Del., and from Philadelphia to Columbia and Atglen, Pa.

Miles of railroad to be electrified	325
Miles of track to be electrified	1300
Electric locomotives required for new electrified operation:	
Passenger	165
Freight	200
Total new electric locomotives required	365
Electric locomotives now in operation	84
Number of passenger trains:	
To be operated by electric locomotives	318
To be operated as multiple unit trains	218
Estimated cost to complete program	$100,000,000

Estimated time to complete program	6 to 7 years
Saving in number of freight trains operated	Approximately 50%
Size of freight trains to be operated	125 cars
Speed of freight trains under electrified operation	25 m.p.h.
Miles of railroad already electrified (Includes 140 miles L.I.R.R.)	333
Miles of track already electrified (Includes 418 miles L.I.R.R.)	960
Total P.R.R. line mileage which will be operated electrically on completion of new program	658
Total P.R.R. track mileage to be operated on completion of new program	2260

APPENDIX C

PART II

ELECTRIFICATION OF THE READING RAILROAD

Announcement by A. T. DICE, *President, on Nov.* 12, 1928

The Board of Directors of Reading Company has approved plans for the electrification of a major portion of the Reading Railway System in the metropolitan district of Philadelphia for the operation initially of most of the suburban trains in this area.

The following lines will be electrified: Reading Terminal to Lansdale; Glenside to Hatboro; Jenkintown to Langhorne, and the Chestnut Hill Branch. This includes the electrification of all four main tracks between Reading Terminal and Wayne Junction, and of the two tracks from Wayne Junction to Lansdale, Langhorne and Chestnut Hill.

It has been decided to use single-phase alternating current at 11,000 volts for propulsion of trains. Overhead trolley wires will be installed and the pantograph type of current collector will be used on cars and locomotives. This wiring will require steel bridges at intervals of about 300 ft. throughout the area of electrification. Active progress is now being made on the extensive detailed plans required. The erection of the catenary overhead wiring will be the first physical work undertaken, and it is planned to begin construction at outlying points. The work will then proceed toward the more congested part of the railroad system. The railroad will build a number of substations at various points for the most effective and reliable distribution of power to all parts of the system.

Type of Coaches

One hundred multiple-unit coaches of the most modern design will be placed in service, releasing 35 steam locomotives now in use and also 120 steam coaches, which will be diverted to service at other points on the system. These cars may be operated separately or combined as trains from one to ten cars each. These coaches will be propelled by their own motors, and trains will be capable of speeds as high as 70 miles per hour, which will be independent of the number of cars operated as one train. They will also be able to accelerate to full speed in very much shorter time than the present steam trains, and will maintain high speeds on heavy grades as well as on level track. It will thus be possible to maintain considerably higher average speed throughout all portions of the runs.

Probably the most important phase of the electrification to be called to the attention of the residents of this territory is the increase in frequency of service as well as speeding up of all trains in this territory. This service will give the cities and towns an average of approximately 25 per cent increase in daily train service with a 20 to 25 per cent saving in time to and from Reading Terminal. The new arrangement will provide express service to the outlying territory throughout the day, instead of providing only local trains at certain times, as at present. Better connections at junction points with through trains will also be provided. All electric and steam trains will stop at the new North Broad Street Station, which will have underground connection with the Broad Street Subway.

Aid to Community Development

It is obvious that the modernizing of service will be of the utmost importance to the territory north and northeast of Philadelphia. It has been the universal experience that following electrification of a railroad bringing with it faster and more frequent service communities multiply and grow with astonishing rapidity. Enhancement of real estate values follows, and the elimination of smoke and noise permits the development of property for home building purposes adjacent to the tracks.

At Wayne Junction a large coach storage yard and electrical repair shop will be erected on the ground between Chestnut Hill and the Tabor branches, and immediately north of Wayne Junction Station, for which ground has already been purchased by the railroad company.

At Chestnut Hill the present station will be changed for electrical operation and facilities will be enlarged to provide a storage yard for a considerable number of the new electric motor cars. At a number of other points changes will be made in station and track facilities to aid in the operation of a high type of electric service.

Coincident with the electrification the company will install modern color light signals in the entire territory, which will replace the present semaphores and "banjo" signals. These signals will not only facilitate the movement of trains, but will provide the maximum of safety that modern railroad engineering has devised.

All the equipment will be designed specially for the Reading Company and include many features never before adopted in an electrification program of this magnitude.

The First Step in the Program

According to a previous announcement of the company, plans had been made for the electrification of the Chestnut Hill Branch as the first step in the program. The revised plans, however, will place this branch last due to the fact that negotiations between the city and the railroad for the elimination of grade crossings have not been consummated.

At the same time tentative plans are being made to include electrification on the Norristown Branch when the present grade crossing elimination program is completed throughout the Manayunk section. Moreover, the plans in all sections are being developed in such a way that it will be possible to extend the service without altering the initial installation, to include through passenger and freight electrification at such time as the railroad company shall find this extension of electrification justifiable.

The total cost of the electrification program will be approximately $20,000,000. Three years will be required to complete the work.

APPENDIX C

PART III

SOME PHASES OF THE RAILROAD SITUATION

Extract from an address by P. E. CROWLEY, *President, New York Central Lines, at the Annual Dinner of The Electric Association, Chicago, Nov.* 15, 1928

While all industry is struggling with the complex questions inevitably raised by modern conditions, the one with which I am most familiar and upon which I am best qualified to speak—the railroad industry—has had and now has grave questions confronting it which call for wise solution, but which can only be solved by an understanding of those questions by those whose business is with the railroad, although not of it, and whose interests lie not only in the successful development of their own business, but in the successful maintenance and the intelligent growth of an adequate and efficient transportation system.

The fundamental need of all industry is money. With the enormous expansion that has been going on in the last decade, that need to the railroads is becoming greater. It is greater because of the enormous expenditure necessary to keep the railroads in proper condition to do the business that is offered them; to make the improvements that are necessary; to improve the state of the art and keep the standards of service so high that the public—that is, the railroads' customers—will be satisfied. To many people the railroads are to a large extent a matter of course. Their interest in them is manifested only in their desire and expectation of fast, reliable and frequent service, both freight and passenger. To meet these demands and needs, the railroads of the country have, since 1920, invested over five billions of new capital in improvements and additions. This has been done during a time when railroad freight rates, which were never high in this country, were in many instances decreasing, and when passenger rates were stabilized at a fixed level. When it is considered that while these vast amounts of money were being invested, freight rates were being decreased, passenger rates were remaining stationary, railroad wages were being pushed to higher levels, railroad materials, supplies and taxes were costing more and railroad expenses as a whole were greater, the achievement, I think, is phenomenal. The question is, can it be kept up under present conditions; and, if not, what can be done to enable this great industry to continue to furnish even more effective service in the future than it has in the past.

Enlarged passenger terminals, new and larger passenger stations, are desired by the public. Widespread demand exists for the elimination of railroad crossings, perhaps the most expensive proposition with which the railroads are confronted. The business of the country requires the enlargement of freight terminals, additional tracks and modern and efficient equipment. In the aggregate it is conservatively estimated that the capital needs of the American railroads are close to a billion dollars a year.

Revenue Increase Is Problem

The railroads have no special road to the acquisition of money. They obtain it in one of three ways: by borrowing or by selling stock, or by revenues from operations. If the revenues from operation after the payment of expenses, do not yield support for their credit, with a safe margin, this money is difficult to obtain, or at least conditions are onerous. In any case, the obligations become greater and the charges on that account increase. The economic need of the railroads is to increase their revenues, and how to do that in the face of the many difficult situations confronting them is the problem in which all of you gentlemen are as interested as are we of the railway industry.

. . . .

I have the greatest faith in the future of our railroads and in their success, but that future and that success are becoming more and more dependent upon full and frank cooperation between the people who use the railroads on the one hand and the railroads themselves on the other. I think the railroads have done, and are doing, their part; but, single-handed, they cannot accomplish the results which would be beneficial to all concerned.

I am taking advantage of the opportunity to talk to this gathering frankly; to ask if it is not possible, in your judgment, for fuller cooperation to be had on this major problem. A great step forward was made some years ago when the regional advisory boards, composed of representatives of the railroads and of users of the railroads, were organized, and much good has been accomplished in the improvement of service by the frank discussions that have taken place in those bodies. But much more remains to be done and if we are to continue to furnish the present service, or better service, if we are to continue to maintain our properties at the standard required by present day conditions, if we are to continue to make such improvements and additions as the growth of the country and the growth of business warrants and demands, then, it seems to me, the time has arrived when we should all act together, because in the ultimate result our interests are the same.

. . . .

It would not be fair for me to omit to mention another field of service in which the electrical industry fills an important sphere. That is the service by electricity in transportation. It is true that this began to be supplied many years ago in places where other means of transportation were unsatisfactory.

Take, for instance, the electrification of the trolleys in the cities. The horse had to go. It was a nuisance upon the streets. The success of electricity there and on subsequently developed interurban lines permitted the development of electric apparatus, I believe, to the point where it was suitable for the increased weights and speeds of steam railway equipment and traffic, in such places as the Baltimore and other tunnels and underground construction, where the smoke and steam of locomotives was objectionable and limited the operation as well as the service to patrons.

A Pioneer Venture

As long ago as 1899 the New York Central began to study the method of operation in and out of Grand Central Terminal, in New York, the approach to which is through a tunnel over two miles long, with an additional three miles upon an elevated structure through city streets fronted by dwellings and business buildings. It was a pioneer venture in respect of operation on the scale that had to be undertaken owing to the fact that it was not feasible to change power upon trains until the limits of New York were passed. With the aid of State Legislation, the cooperation of the state and municipal authorities and of the electrical industry, a wise plan was made and the operation has been successful, particularly from the standpoint of developing the suburban traffic, which, carried at the lowest rates afforded such traffic, so far as my knowledge pertains, in this country, is continually growing and making increased demands upon our facilities. While we do not separate our net returns from this traffic, owing to the fact that it is interwoven with long distance traffic which also comes in over the same line and to the same terminal, we can with confidence state that there is no available method by which the conditions and patronage could be satisfied with steam operation. For this solution of our problem and for its continued success, particularly from the operating standpoint, I wish to make grateful acknowledgment to the electric industry.

For many years the traffic via the Michigan Central Railroad operated by ferry across the Detroit River. This was, however, unsatisfactory, particularly in seasons when ice and fog interfered with schedules and comfort. By the construction of a tunnel under the river the railroad was made continuous; but it would have been out of the question, in my belief, to have a satisfactory result from this tunnel operation without the availability of electric power. This construction and operation has placed the service via the Michigan Central on a plane previously unknown and has increased its capacity and the satisfaction of its patrons.

We are just entering into a third major installation of electric power upon the New York Central Lines—this time in and about Cleveland. As in Detroit, the work is being done in connection with a passenger station development, which involves considerable underground operation and which, I believe, specially invites the use of electricity. On the other hand, in the new passenger terminal now nearing completion in Buffalo and in the proposed Union Station at Cincinnati there is no immediate need for electrification, as the trains will be operated entirely in the open. In other words, gentlemen, Cincinnati presents one problem, New York another and Chicago still another. Each differs from the others, as may be said of almost every city on our system. Each has problems of its own, and the local situation must be studied most carefully to develop the lines along which we should move to best serve each particular community, and not with the thought that what has been done in New York, or anywhere else, is the right thing to do at any other place. Take this great city of Chicago, where we are meeting this evening; a prime essential of the operating problem of the many railroads that enter here is the expedited interchange of freight between them. At no other point in the world is there interchange quite comparable to this. It is a problem, unique in itself. The Chicago situation must be settled and we are now engaged in studying it; and it will be solved if the railroads and the various local public bodies cooperate with the thought of arriving at a conclusion that will best serve the interests of the city and its railroads.

Experimenting with Types of Motive Power

We are also experimenting with self-contained electric types of motive power which can operate either from wayside current, or where such is not available, by electricity which is produced by a Diesel power plant on the locomotive itself. We hope these experiments will result in the availability of a satisfactory unit of power, economically reasonable in cost and obsolescence as well as operation and maintenance, with which to meet the requirements which may develop from time to time in this general field of operation, particularly industrial switching, within congested municipal limits.

We have additional experiments in progress with advanced types of steam motive power for various fields of operation so that we may obtain first hand knowledge of their relative merits and availability and economic value for our diversified service, geographical and traffic conditions.

We of the railroad industry are keenly alert as to what you gentlemen of the electrical age here in America are doing—to your brilliant and your constant progress. If we were not watching you keenly, we would hardly be worth our posts of stewardship. We are almost if not quite as interested as you in the progress of your industry, nowhere more so than in its infinitely varied and helpful relationship to the rail transport industry upon this continent—a relationship in which both industries have prospered for some years past and in which they both should continue to prosper for many years to come.

APPENDICES

1. Certified Accounts, Surplus Account, Statement of Income and Expenses of National Electric Light Association for Administrative Year Ended June 30, 1929 and List of Securities
2. Registration of Attendance at the Fifty-second Convention
3. Constitution of the National Electric Light Association
4. Organization Personnel
5. List of Member Companies
6. Presidents and Honorary Members of the Association
7. Conventions of the Association
8. Numbering of Proceedings

APPENDIX 1

CERTIFIED ACCOUNTS

NATIONAL ELECTRIC LIGHT ASSOCIATION

BALANCE SHEET, JUNE 30, 1929

ASSETS

FURNITURE AND FIXTURES	$59,837.92	
Less—Depreciation reserve	18,417.23	
		$41,420.69
INVENTORY OF PUBLICATION PAPER STOCK		2,406.75
INVESTMENT SECURITIES, AT COST		456,474.25
ACCOUNTS RECEIVABLE:		
Publications' sales accounts	$4,640.04	
Interest	5,476.18	
Miscellaneous accounts	13,707.91	
		23,824.13
CASH IN BANK OR ON HAND:		
Time certificates of deposit—Fidelity-Union Trust Co	$313,394.86	
Time certificates of deposit—Bankers Trust Co	475,000.00	
Checking account—Bankers Trust Co	10,016.32	
Cashiers' account—Bankers Trust Co	500.00	
Office cash	3,000.00	
		801,911.18
ADVANCES FOR TRAVELING EXPENSES		5,181.50
		$1,331,218.51

LIABILITIES

ACCOUNTS PAYABLE:		
Vouchers payable	$53,156.43	
Accrued expenses	79,946.23	
		$133,102.66
PREPAID DUES:		
For six months ending December 31, 1929	$757,008.55	
For subsequent years	77.00	
		757,085.55
UNADJUSTED CREDITS:		
Unapplied miscellaneous receipts		456.50
JOINT RESEARCH FUND		5,412.48
INDUSTRIAL HEATING COMMITTEE, STEEL TREATING EXPOSITION		400.00
RESERVE FOR CONTINGENT CONTRIBUTIONS		100,000.00
SURPLUS, PER ACCOMPANYING STATEMENT		334,761.32
		$1,331,218.51

We have audited the books and accounts of the National Electric Light Association for the fiscal year ending June 30, 1929, and we certify that, in our opinion, the above balance sheet and accompanying statements of income and expenses and of surplus are correctly prepared therefrom and fairly set forth the financial position of the Association at June 30, 1929, and the results of operations for the year.

PRICE, WATERHOUSE & CO.

56 Pine Street,
New York.

NATIONAL ELECTRIC LIGHT ASSOCIATION

Statement of Income and Expenses

for the Fiscal Year Ending June 30, 1929

Income

Dues:		
Class "A" members	$1,153,274.02	
Class "B" members	44,488.03	
Class "C" members	532,50	
Class "D" members	118,594.30	
Class "E" members	9,072.00	
Class "F" members	8,228.34	
Class "G" members	2,280.50	
Class "H" members	2,510.00	
Class "I" members	310.00	
		$1,339,289.69
Gross Proceeds from Publications and Miscellaneous Sales		77,056.90
Miscellaneous Income:		
Interest on bank balances	$21,959.18	
Interest and dividends from securities owned	17,832.34	
		39,791.52
		$1,456,138.11

Expenses

Headquarters Running Expenses:		
Salaries, wages and pension	$340,155.35	
Rent, electric light and power	55,258.31	
Postage, telephone, telegrams and messenger	21,942.63	
Printing, stationery and office supplies	16,918.68	
Traveling and incidentals	50,524.63	
Newspaper clipping service	55.15	
Insurance	6,992.44	
Subscriptions to periodicals	4,382.53	
Miscellaneous	8,103.20	
Depreciation of furniture and fixtures	3,727.11	
		$508,060.03
Publications Cost		192,479.67
Talking Motion Picture		35,817.00
Geographic Division		271,213.04
National Sections:		
Accounting	$194.69	
Commercial	22,062.22	
Public relations	785.47	
Engineering	44,093.14	
		67,135.52
National Committees		869.89
Farm Electrification Activities		88,009.53
Advertising Copy Service		10,115.04
Inductive Coordination Activities		63,937.46
Convention and Exhibition		41,806.43
Dues Paid to Other Organizations		12,423.00
Federal Trade Investigation		12,827.92
Joint Committee of National Utility Associations		30,000.00
Provision for Contingent Contributions		100,000.00
Excess of Income Over Expenses for the Year Carried to Surplus Account		21,443.58
		$1,456,138.11

APPENDIX 3

CONSTITUTION
of the
NATIONAL ELECTRIC LIGHT ASSOCIATION

As amended and adopted at the Fifty-second Convention, Atlantic City, N. J., June 7, 1929

ARTICLE I—NAME

This Association shall be entitled the National Electric Light Association.

ARTICLE II—OBJECT

The object of this Association shall be to advance the art and science of the production, distribution and use of electrical energy for light, heat and power for public service.

In the furtherance of this object its activities shall be largely educational and for the fullest development of the electrical engineering arts and sciences in all their branches.

It shall not be engaged in business.

ARTICLE III—MEMBERSHIP

SECTION 1. Members shall be divided into ten classes—Central Station Company Members (Class A), Central Station Individual Members (Class B), Invited Members (Class C), Manufacturer Company Members (Class D), Manufacturer Individual Members (Class E), Associate Company Members (Class F), Associate Individual Members (Class G), Foreign Company Members (Class H), Foreign Individual Members (Class I), and Honorary Members.

SECTION 2. Class A members shall be regularly incorporated public service companies engaged in producing and supplying electrical energy for light, heat or power for public use. They shall be entitled, through their regularly accredited delegates, to attend all meetings of the Association, to vote and to hold any office.

SECTION 3. Class B members shall be officers or employees of Class A members, elected or continued from year to year with the written approval of the Class A members with which they are connected. They shall have the same privileges as Class A members, except the right to vote at the executive sessions of the Association.

SECTION 4. Class C members shall be officials of public service commissions, instructors, teachers or practitioners of engineering and related sciences or of other professions who are interested in the art of applied electricity. They may become or remain members only upon the invitation and approval of the National Executive Committee. They shall have the same privileges as Class B members, except the right to hold elective office.

SECTION 5. Class D members shall be companies or firms engaged in the manufacture of apparatus, machinery, equipment, supplies or material for the production or use of electrical energy. They shall be entitled, through their regularly accredited delegates, to attend all meetings of the Association, to vote and to hold offices not restricted by provisions of this Constitution to other classes (see Article V—Officers).

SECTION 6. Class E members shall be officers or employees of Class D members, elected or continued from year to year with the written approval of the Class D members with which they are connected. They shall have the same privileges as Class D members, except the right to vote at the executive sessions of the Association.

SECTION 7. Class F members shall be companies or firms of electrical wholesalers, contractors, dealers, electrical or mechanical engineers, publishers and associations—corporations or individuals—who are interested in advancing the use of electrical energy, and are not engaged in its production or distribution. They shall have the same privileges as Class D members, except the right to vote at executive sessions.

SECTION 8. Class G members shall be officers or employees of Class F members, elected or continued from year to year with the written approval of the Class F members with which they are connected. They shall have the same privileges as Class F members.

SECTION 9. Class H members shall be individuals or corporations not residents of the United States or of Canada, engaged in the central station industry, or interested in advancing the use of electrical energy, who shall ally themselves with this Association. They shall have the same privileges as Class A and Class D members, except the right to hold elective office or to vote at executive sessions.

SECTION 10. Class I members shall be officers or employees of Class H members, elected or continued from year to year with the written approval of the Class H members with which they are connected. They shall have the same privileges as Class H members.

SECTION 11. Honorary members shall be elected upon unanimous recommendation of the National Executive Committee and shall be approved by a two-thirds vote of the Association. They shall have the same privileges as Class A and Class D members, except the right to vote and to hold office.

SECTION 12. Individual members (Class B, Class C, Class E, Class G and Class I) may purchase, at member price, reports, proceedings, handbooks and other literature that may be published by the National Electric Light Association for general distribution.

ARTICLE IV—DUES

SECTION 1. The annual dues of Central Station Company Members (Class A) shall be based on the gross revenues from the sale (retail and otherwise) of electrical energy (Operating Revenue—Sales of Current) by the company during the preceding calendar year. The annual dues of a company with such revenue amounting to, but not in excess of, Fifty Thousand Dollars ($50,000), shall be at the rate of Fifty Cents (50c.) per thousand dollars of its Operating Revenue—Sales of Current. The minimum dues of any Class A member shall not be less than Ten Dollars ($10) per annum. The annual dues of a company having Operating Revenue—Sales of Current of over Fifty Thousand Dollars ($50,000) shall be one-twelfth of one per cent (1/12 of 1%) of such Operating Revenue—Sales of Current.

No syndicate, holding company or other corporation or association, controlling or managing central station companies, shall be eligible to membership as a Class A member, unless all of its controlled central station companies are Class A members of the Association in good standing, in which case such syndicate, holding company or other corporation or association may become a Class A member after being duly elected and upon payment of dues of Fifty Dollars ($50) per annum.

SECTION 2. The annual dues of Central Station Individual Members (Class B) shall be Three Dollars ($3).

SECTION 3. The annual dues of Invited Members (Class C) shall be fixed by the National Executive Committee and shall not exceed Five Dollars ($5).

SECTION 4. The annual dues of Manufacturer Company Members (Class D), manufacturing or selling apparatus, machinery, equipment, supplies or material for the production, distribution, consumption and translation of electrical energy to Class A and Class F members, or to corporations, firms or individuals eligible to Class A or Class F membership, shall be fixed annually by the National Executive Committee.

SECTION 5. The annual dues of Manufacturer Individual Members (Class E) shall be Three Dollars ($3).

SECTION 6. The annual dues of Associate Company Members (Class F) shall be based on the gross sales from the sale of electrical apparatus, equipment, appliances, publications or service by the company, firm or individual during the preceding calendar year. The rate of dues for Class F members shall be one one-hundredth of one per cent (1/100 of 1%) of such gross sales for such period. The minimum dues of any Class F member shall be Twenty-five Dollars ($25) per annum, which minimum dues apply only when the gross sales during the preceding calendar year were not greater than Two Hundred and Fifty Thousand Dollars ($250,000).

SECTION 7. The annual dues of Associate Individual Members (Class G) shall be Three Dollars ($3).

SECTION 8. The annual dues of Foreign Company Members (Class H) shall be Fifty Dollars ($50).

SECTION 9. The annual dues of Foreign Individual Members (Class I) shall be Five Dollars ($5).

SECTION 10. In the event that an applicant for Class A, Class D or Class F membership is elected after January 1, the dues for the remainder of the year, ending December 31, shall be pro-rated on a monthly basis.

SECTION 11. In the event that an applicant for Class B, Class E and Class G membership is elected after July 1, the dues for the remainder of the year shall be Two Dollars ($2), which will entitle the member to the *National Electric Light Association Bulletin* for the same period.

SECTION 12. Class A, Class D or Class F members who may elect to collect for the Association the dues of their Class B, Class E or Class G members upon an installment basis, may do so in accordance with a plan of payment approved by the National Executive Committee. In the event that a Class B, Class E or Class G member leaves the employ of the member company, the member company shall so notify the Association and shall be responsible only for the proportion of the dues of the member up to the date of such notice.

SECTION 13. The annual dues of the members of the National Electric Light Association residing or engaged in business in Canada, who are members of the Canadian Electrical Association, shall be fixed by the National Executive Committee.

SECTION 14. All dues, fixed and percentage, shall be paid directly to the Treasurer of the National Electric Light Association.

SECTION 15. All dues shall be payable in advance and shall cover the period of the calendar year. Any member in arrears for sixty (60) days shall be suspended from all privileges of membership, but may be reinstated when all outstanding dues have been paid.

SECTION 16. All dues of members (Class A, Class B, Class C, Class D, Class E, Class F, Class G, Class H and Class I) include subscription to the *National Electric Light Association Bulletin.*

ARTICLE V—OFFICERS

SECTION 1. The officers of this Association shall be a President, four Vice-Presidents, a Treasurer, a Managing Director and a Secretary.

SECTION 2. The President, four Vice-Presidents and Treasurer shall be elected from Class A or Class B members to serve one year from July 1, or until their successors shall have been elected. The President shall not be eligible for immediate reelection to the same office. The President shall preside at all meetings of the Association and of the National Executive Committee, and shall perform such other duties as may be provided for in this Constitution or by vote of the Association. In case of the absence, disability or death of the President, his office shall be filled by the Vice-Presidents, in the order of their seniority.

SECTION 3. The National Executive Committee shall consist of the President, the retiring president, the four Vice-Presidents, the Treasurer, the presiding officer or other duly accredited representative of each of the Geographic Divisions, the chairman of each of the National Sections, and eleven members at large, six of whom shall be chosen from Class A or B members, three from Class D or E members and two from Class F or G members, to be elected by Class A and D members at the annual convention. The eleven members at large shall each be elected to serve terms of three years (except the two F or G members, each of whom shall be elected for a term of one year), except at the first election, two Class A or B members shall be elected for one year, two Class A or B members for two years, and two Class A or B members for three years, and one Class D or E member for one year, one Class D or E member for two years and one Class D or E member for three years. The President of the Association shall act as Chairman of the National Executive Committee.

In case the presiding officer, or other duly accredited representative of a Geographic Division, or the chairman of a National Section, is unable to attend any meeting of the National Executive Committee, he may appoint a delegate to represent such Division or Section at such meeting.

SECTION 4. The National Executive Committee shall be the governing body of the Association, shall manage its affairs, and shall pass upon all applications for membership and upon the eligibility of representatives, subject to this Constitution and such special rules or regulations as may be adopted by the Association from time to time. Seven members of the National Executive Committee shall constitute a quorum.

SECTION 5. The Treasurer shall perform the duties assigned to him by the National Executive Committee, subject to its approval. He shall give a security bond in such sum and with such qualifications as the National Executive Committee may from time to time prescribe.

SECTION 6. The Managing Director shall be appointed by the President, and his appointment confirmed by the National Executive Committee. He shall have charge of all the work of the Association, including the appointment and direction of a Headquarters staff under the general direction of the President and National Executive Committee.

SECTION 7. The Secretary shall be appointed by the President and be confirmed by the National Executive Committee. He shall serve for one year from the first of the month next following the date of the President's election, or until his successor is appointed and confirmed. He may be a member of any class and shall be eligible for reappointment without limit, and shall perform such duties as the Managing Director may direct.

ARTICLE VI—ELECTION OF OFFICERS

SECTION 1. At the first meeting of the executive session of the annual convention there shall be chosen a Nominating Committee, to be composed of five accredited representatives from Central Station Company Members (Class A) in the following manner:

Any accredited representative of a Central Station Company Member (Class A) shall have the privilege of making nominations and, when such nominations are seconded by any other similarly accredited representative, that nominee shall be one of those to be voted for. Nominations in this manner may continue until a resolution shall be adopted to close the lists. After the lists are closed, a ballot shall then be taken. The accredited representative of any Central Station Company Member (Class A) shall have the right to vote for five of those placed in nomination in the manner described in this section. The five nominees receiving the highest number of votes shall constitute a Nominating Committee.

The Nominating Committee shall hold open meetings at times and places to be announced, and at these meetings any accredited representative of a Central Station Company Member (Class A) or a Manufacturer Company Member (Class D) may suggest nominees for any of the offices to be filled.

At a meeting of the executive session, the Nominating Committee shall bring in the names of those recommended by it for the several offices to be filled and an election shall be held.

The submission of names by the Nominating Committee shall not, however, debar any accredited representative of a Central Station Company Member (Class A) or a Manufacturer Company Member (Class D) from making nominations for any or all of the several offices to be filled. Such nominations, if seconded, shall be submitted for election at the same time and in the same manner as those of the Nominating Committee. Whenever there are more nominees than vacancies to be filled, the election shall be decided by ballot. When there is no contest for office, the secretary of the executive session may be instructed by a *viva voce* vote to cast the ballot for those recommended by the Nominating Committee.

SECTION 2. Vacancies in office may be filled by the National Executive Committee to cover unexpired terms.

ARTICLE VII—COMMITTEES

SECTION 1. The President shall appoint a Public Policy Committee, four members of which shall be selected by and from the Executive Committee of the Public Relations National Section, all subject to the approval of the National Executive Committee, and shall name such other committees as may seem to him desirable, subject to the approval of the National Executive Committee, and he shall appoint the members thereof.

SECTION 2. Unless otherwise provided, the terms of members of committees shall expire with the end of the month of June next following their appointment unless sooner terminated by the National Executive Committee.

ARTICLE VIII—NATIONAL SECTIONS

SECTION 1. The National Executive Committee may authorize the formation of National Sections, as it may deem necessary, for the consideration and treatment of certain subjects; shall define the names of such National Sections; shall specify their scope of operations, and shall approve, subject to the constitutional provisions herein, the Committee organization for each Section.

SECTION 2. There shall be a Public Relations National Section having an Executive Committee, and the membership of the Executive Committee of this Section shall be limited to executive officers of member companies. The President shall appoint four (4) members of the said Executive Committee to the Public Policy Committee, subject to the approval of the National Executive Committee and the Public Policy Committee. There shall also be an Accounting National Section, a Commercial National Section, and an Engineering National Section.

SECTION 3. Each National Section shall have an Executive Committee and such other committees as may be approved by the National Executive Committee.

SECTION 4. The Executive Committee of a National Section shall be the governing board of the Section.

SECTION 5. The Executive Committee of a National Section shall consist of a Chairman, the retiring Chairman, not more than six (6) members at large, the Chairmen of the other Committees of the Section, and the Chairmen of corresponding Sections of the Geographic Divisions. There may also be one or more Vice-Chairmen. The Chairman of each National Section shall be a member of the Executive Committee of each of the other National Sections.

SECTION 6. Each of the National Sections' Executive Committees shall appoint a Nominating Committee consisting of five (5) members, and the Chairman shall announce the names of the members so appointed at the first executive sessions of the annual meetings of the Sections. These Nominating Committees, at subsequent executive sessions of the Sections, shall submit the names of fifteen (15) members of the Association. The submission of names by the Nominating Committees shall not, however, debar any accredited representative of a Central Station Company Member (Class A) or a Manufacturer Company Member (Class D) from making nomination for any or all of the several offices to be filled. Such nomination, if seconded, shall be submitted with the fifteen (15) names presented by the Nominating Committee. From this list the President Elect shall select and appoint the Chairman, Vice-Chairmen and members at large of each National Section for the administrative year beginning July 1 next, as herein provided.

SECTION 7. The terms of office of the Chairman and Vice-Chairmen shall be one year each. The terms of office of the six (6) members at large shall be two years each, except, at the first appointment, three of such members shall be appointed for terms of one year and three for two years each. The officers and six members at large shall be eligible to immediate reappointment to the same offices.

SECTION 8. The Chairman of a National Section shall be the Chairman of the Section's Executive Committee and shall *ipso facto* become a member of the National Executive Committee. If he be unable to attend any meeting of the National Executive Committee, he may appoint a delegate to represent him, such delegate being a Class B or Class E member of the Association.

SECTION 9. Vacancies, exclusive of the Chairmen of the corresponding Sections of the Geographic Divisions, occurring in the Executive Committee of a National Section shall be filled by the President, subject to the approval of the Executive Committee.

SECTION 10. Except as prescribed in Section 2 of Article VIII, other Committees of a National Section shall consist of a Chairman and members at large appointed by the Chairmen of the Section, subject to the approval of the President, and the Chairmen of the corresponding Committees of the Geographic Divisions.

SECTION 11. The National Executive Committee may authorize a National Section to create, or continue, one or more special committees, the personnel of which may consist solely of members at large, who shall be appointed by the Section Chairman, subject to the approval of the President.

SECTION 12. Meetings of the Executive Committee of a National Section shall be held upon call of its Chairman; meetings of other committees of a National Section may be held upon call by their respective Chairmen subject to the approval of the Section Chairman.

SECTION 13. Not later than August 15th of each year, the Executive Committee of each National Section shall prepare and present, through its Chairman, to the President, a detailed budget of its estimated expenses for the year beginning July 1st, immediately preceding, and shall also file with the President a detailed statement of the actual expenses of the Section incurred during the preceding administrative year.

SECTION 14. The National Executive Committee, after consideration and approval of the budget of a National Section submitted to it by the President, shall, upon certification of the Chairman of the Section, authorize the Treasurer of the Association to pay the indebtedness incurred by the Section. The expenses of a National Section must be limited to the appropriations authorized by the National Executive Committee.

SECTION 15. The Constitutions of the Accounting National Section, the Commercial National Section, the Engineering National Section (prior to May 21, 1926, Technical National Section) and the Public Relations National Section are annulled, and the Constitution of the National Electric Light Association shall govern the organization and operations of any and all National Sections authorized bv the National Executive Committee.

SECTION 16. No person not a member of the National Electric Light Association shall be eligible to membership in any National Section of the Association.

ARTICLE IX—GEOGRAPHIC DIVISIONS

SECTION 1. A Geographic Division shall be a sectional organization embracing two or more adjacent states, which states shall be represented in the Division by state electrical central station associations or central station branches of state public utility associations, and where there are no such existing state organizations the membership of the National Electric Light Association within such state or states shall constitute the representation of the state or states within the Geographic Division.

SECTION 2. There shall be thirteen Geographic Divisions, designated and defined as follows:

Eastern—New Jersey, New York, Pennsylvania.
East Central—Kentucky, Ohio, West Virginia.
Great Lakes—Illinois, Indiana, Michigan, Wisconsin.
Middle Atlantic—Delaware, District of Columbia, Maryland, Virginia.
Middle West—Iowa, Kansas, Missouri, Nebraska.
New England—Connecticut, Maine, Massachusetts, New Hampshire, Rhode Island, Vermont.
North Central—Minnesota, North Dakota, South Dakota.
Northwest—Idaho, Montana, Oregon, Utah, Washington, Alaska.
Pacific Coast—Arizona, California, Nevada, Hawaii, Philippine Islands.
Rocky Mountain—Colorado, New Mexico, Wyoming.
Southeastern—Alabama, Cuba, Florida, Georgia, North Carolina, South Carolina, Tennessee, Porto Rico.
Southwest—Arkansas, Louisiana, Mississippi, Oklahoma, Texas.
Canadian—Canada; represented by the Canadian Electrical Association.

SECTION 3. The National Executive Committee may, on its own motion or upon the application of the Executive Committee of one or more adjacent Geographic Divisions, modify the boundaries of the territory of any of the thirteen Geographic Divisions or add to or subtract from the existing number of Geographic Divisions.

SECTION 4. The presiding officer, or other duly accredited representative, selected by and from the Executive Committee of each of the Geographic Divisions, shall represent the Division as a member of the National Executive Committee. Such presiding officer, or other duly accredited representative, shall be a Class A or Class B member of the Association.

SECTION 5. The form of organization of each Geographic Division shall be in conformity with the Constitution of the National Electric Light Association, subject to ratification by the National Executive Committee and subject to amendment by those members of the Geographic Division qualified to vote. All proposed changes in and amendments to the organization of a Geographic Division shall be submitted to the National Executive Committee for approval before adoption.

SECTION 6. Not later than August 15th each year the Executive Committee of each Geographic Division shall prepare and present to the National Executive Committee a detailed budget of the estimated expenses of its Geographic Division for the year beginning July 1st immediately preceding, and shall also file with the National Executive Committee a detailed statement of the actual expenses of its Geographic Division during the preceding administrative year.

SECTION 7. The National Executive Committee, after consideration and approval of the detailed budget submitted by a Geographic Division, shall authorize the Treasurer of the Association to pay to the proper officer of the Geographic Division an amount which, in the judgment of the National Executive Committee, is necessary to finance the Geographic Division properly, but the amount in no case shall exceed 50 per cent (50%) of the yearly dues received from Classes A [Class A dues, for this purpose, to be figured at the rate of one-fifteenth of one per cent (1/15 of 1%) where "Operating Revenue—Sales of Current" is over Fifty Thousand Dollars ($50,000)], B, E, F and G members of such Geographic Division.

The expenditures of a Geographic Division, in so far as the responsibility of the National Electric Light Association is concerned, must not exceed appropriations authorized by the National Executive Committee.

ARTICLE X—STATE ASSOCIATIONS

SECTION 1. State Associations may be organized as unit sections of the thirteen Geographic Divisions.

SECTION 2. The presiding officer, or other duly accredited representative, selected by and from the Executive Committee of a State Association, shall represent such State Association in its Geographic Division as a member of the Geographic Division's Executive Committee. Such presiding officer, or other duly accredited representative, shall be a Class A or Class B member of the National Electric Light Association.

SECTION 3. The form of organization of each State Association shall be in conformity with the Constitution of the National Electric Light Association.

ARTICLE XI—COMPANY SECTIONS

SECTION 1. Upon the application to it by any Class A member, having in its employ not less than ten Class B members, the National Executive Committee may authorize the organization of any or all of the officers and employees of said Class A member into a Company Section, club, or other similar organization, of the National Electric Light Association, the officers, executive committee and committee chairmen of which shall be elected from Class B membership.

SECTION 2. A Company Section, club or other similar organization may include as Limited Members those employees of Class A members who desire to participate in the local organization's activities, but who are not yet qualified for Class B membership. The dues from such Limited Members shall go into the local treasury.

ARTICLE XII—LOCAL CLUBS

SECTION 1. Upon the application to it by ten members of any class, the National Executive Committee may, with the approval of the State Association or Geographic Division concerned, authorize the formation of a local club, or other similar organization, to which all classes of Association members residing or engaged in business in such community shall be eligible to membership.

SECTION 2. The form of organization of each local club shall be in conformity with the Constitution of the National Electric Light Association.

ARTICLE XIII—MEETINGS

SECTION 1. An annual convention shall be held in May or June of each year, unless otherwise directed by the National Executive Committee, and in such places and on such dates as the National Executive Committee may designate.

SECTION 2. A member company shall not be permitted to entertain any convention of any national conference, but all expenses pertaining thereto shall be paid out of the treasury of the Association, subject to the approval of the National Executive Committee.

ARTICLE XIV—NATIONAL CONFERENCES

SECTION 1. Upon application to it of at least twenty members, the National Executive Committee may call a National Conference upon any designated subject or subjects affecting the industry as represented by the National Electric Light Association, due notice of which Conference shall be sent to each member of the Association.

SECTION 2. The expenses of National Conferences may be met by appropriations made by the National Executive Committee from the general funds of the Association or by special contribution.

ARTICLE XV—QUORUM

SECTION 1. Twenty members, of which not less than fifteen shall be Class A members of the Association, shall constitute a quorum for the transaction of business.

ARTICLE XVI—VOTING AND PROXIES

SECTION 1. A roll call shall be ordered on the demand of any ten Class A or Class D members on any question before the Association. Where it is not otherwise specified in this Constitution, the authorized delegates shall cast their votes by rising.

SECTION 2. Voting by proxy shall not be allowed at any meeting of the Association, or of any of its committees.

ARTICLE XVII—PARLIAMENTARY RULES

SECTION 1. Roberts' Rules of Order shall be the governing parliamentary law of the Association in all cases not definitely provided for by its Constitution or its own rules.

ARTICLE XVIII—EXHIBITIONS

SECTION 1. The National Executive Committee, upon application to it by one or more members of Class A, Class D or Class F, may authorize the holding of such exhibitions and of such contest at such times and places as it may designate and assign. Such exhibitions and such contests held under the auspices of the National Electric Light Association shall be governed by such rules and regulations as the National Executive Committee, or its delegates, shall prescribe and may be financially supported by the National Electric Light Association at the discretion of the National Executive Committee.

ARTICLE XIX—ASSOCIATION MAGAZINE

SECTION 1. The National Electric Light Association shall publish a monthly bulletin which shall be under the direction of the Managing Director, subject to the approval of the National Executive Committee as to the policy and scope thereof and the expenditures therefor. The annual subscription price of the *National Electric Light Association Bulletin* shall be Three Dollars ($3), and is included in the annual dues of all classes of members.

ARTICLE XX—PERMANENT OFFICE

SECTION 1. The permanent office of the Association shall be maintained in the City of New York, and shall be located, furnished and governed in such manner as the National Executive Committee may from time to time direct.

ARTICLE XXI—AMENDMENTS

SECTION 1. Amendments to this Constitution shall be offered in writing and shall be referred, before being acted upon, to a committee to be elected by the Association. A two-thirds vote of all Class A and D members present shall be necessary for their adoption.

APPENDIX 4

Organization Personnel

of the

National Electric Light Association

for the

Administrative Year
July 1, 1928—June 30, 1929

National Executive Committee

Officers

President, P S Arkwright, Georgia Power Co, Atlanta, Ga
Vice-President, M S Sloan, The New York Edison Co, New York, N Y
Vice-President, W A Jones, Henry L Doherty & Co, New York, N Y
Vice-President, J F Owens, Oklahoma Gas & Electric Co, Oklahoma City, Okla
Vice-President, Marshall E Sampsell, Central Illinois Public Service Co, Chicago, Ill
Treasurer, P S Young, Public Service Electric & Gas Co, Newark, N J
Managing Director, Paul S Clapp, National Electric Light Association, New York, N Y
Secretary, A Jackson Marshall, National Electric Light Association, New York, N Y

Members at Large

(Terms expiring June 30th, 1929)

H T Sands, *ex-officio,* Electric Bond & Share Co, New York, N Y
C L Collens, Reliance Electric & Manufacturing Co, Cleveland, Ohio
G E Cullinan, Graybar Electric Co, Inc, New York, N Y
E W Lloyd, Commonwealth Edison Co, Chicago, Ill
Harry Reid, National Electric Power Co, New York, N Y
James R Strong, Tucker Electrical Construction Co, New York, N Y

(Terms expiring June 30th, 1930)

D C Barnes, Stone & Webster, Inc, Boston, Mass
H P Liversidge, The Philadelphia Electric Co, Philadelphia, Pa
Gerard Swope, General Electric Co, New York, N Y

(Terms expiring June 30th, 1931)

John P Coghlan, Pacific Gas & Electric Co, San Francisco, Cal
H M Edwards, The New York Edison Co, New York, N Y
E M Herr, Westinghouse Electric & Manufacturing Co, New York, N Y

National Section Chairmen

Accounting—J F Ford, The Philadelphia Electric Co, Philadelphia, Pa
Commercial—Marshall E Sampsell, Central Illinois Public Service Co, Chicago, Ill
Engineering—E C Stone, Duquesne Light Co, Pittsburgh, Pa
Public Relations—J F Owens, Oklahoma Gas & Electric Co, Oklahoma City, Okla

Geographic Division Presidents

Canadian—P S Gregory, The Shawinigan Water & Power Co, Montreal, Can
Eastern—F R Phillips, Duquesne Light Co, Pittsburgh, Pa
East Central—C S MacCalla, Pennsylvania-Ohio Power & Light Co, Youngstown, Ohio
Great Lakes—J E Johnson, Illinois Power & Light Corp, Chicago, Ill
Middle West—Ralph T Smalley, Kansas Electric Power Co, Lawrence, Kans
New England—Irvin W Day, The Connecticut Light & Power Co, Waterbury, Conn
North Central—L M Pharis, Minnesota Power & Light Co, Duluth, Minn
Northwest—R M Boykin, Puget Sound Power & Light Co, Seattle, Wash
Pacific Coast—Paul M Downing, Pacific Gas & Electric Co, San Francisco, Cal
Rocky Mountain—Clare N Stannard, Public Service Co of Colorado, Denver, Colo
Southeastern—C A Collier, Georgia Power Co, Atlanta, Ga
Southwestern—J G Holtzclaw, Gulf States Utilities Co, Beaumont, Texas

CHARLES A COFFIN PRIZE COMMITTEE

By action of its Board of Directors, the General Electric Company has set aside a fund of $400,000 to be known as the "Charles A Coffin Foundation," the income from which, amounting to approximately $20,000 a year, will be available for encouraging and rewarding service in the electrical field by giving prizes to its employees, recognition to lighting, power and railway companies, for improvements in service to the public and fellowships to graduate students and funds for research work at technical schools and colleges

The Foundation will be controlled and administered by a Foundation Committee appointed by the Board. This Committee, within the limits of the purposes for which the Foundation is created, will have power to change the conditions applicable to the distribution of the fund and the amounts for each particular purpose

A gold medal, to be known as the "Charles A Coffin Medal," will be awarded annually to the public utility operating company within the United States which, during the year, has made the greatest contribution toward increasing the advantages of the use of electric light and power for the convenience and well-being of the public and the benefit of the industry. The company receiving the medal will also receive one thousand dollars ($1,000) for its employees' benefit or similar fund

A Committee to be named by the National Electric Light Association and known as the "Charles A Coffin Prize Committee of the National Electric Light Association," which shall consist of its President, Chairman of its Public Policy Committee and a third member nominated by them, will award this medal, acting with the advice and cooperation of a committee appointed by the Foundation Committee. The expenses of the Committee are to be paid out of the income of the Foundation

Chairman, P S Arkwright, *President, National Electric Light Association,* Georgia Power Co, Atlanta, Ga
R H Ballard, *Chairman, Public Policy Committee,* Southern California Edison Co, Los Angeles, Cal
Samuel W Stratton, *President,* Massachusetts Institute of Technology, Boston, Mass
William W Trench, *Secretary,* Charles A Coffin Foundation, Schenectady, N Y

CODES AND STANDARDS COMMITTEE

Determination of broad policies with respect to codes and standards to serve as a guide for the committees handling such matters

To establish rules and instructions of procedure for representatives of the power industry

To assist in broad coordination of the activities of the power industry with those of other interests in taking an active part in the establishment of codes and standards

Chairman, Irvin W Day, The Connecticut Light & Power Co, Waterbury, Conn
W S Finlay, Jr, West Penn Electric Co, Pittsburgh, Pa
G H Harries, H M Byllesby & Co, Chicago, Ill
C A Pratt, Electric Bond & Share Co, New York, N Y
Marshall E Sampsell, Central Illinois Public Service Co, Chicago, Ill
Frank W Smith, The United Electric Light & Power Co, New York, N Y
W G Vincent, Jr, Pacific Gas & Electric Co, San Francisco, Cal

CONSTITUTION AND BY-LAWS COMMITTEE

To investigate on behalf of the President and National Executive Committee any proposed changes in the National Association's Constitution and By-Laws; to investigate and standardize all provisions of the Constitution and By-Laws by Geographic, Company or any other Divisions or Sections of the Association

Chairman, R F Pack, Northern States Power Co, Minneapolis, Minn
P S Arkwright, *ex-officio,* Georgia Power Co, Atlanta, Ga
W A Jones, Henry L Doherty & Co, New York, N Y
J F Owens, Oklahoma Gas & Electric Co, Oklahoma City, Okla
Marshall E Sampsell, Central Illinois Public Service Co, Chicago Ill
M S Sloan, The New York Edison Co, New York, N Y

ELECTRIFICATION OF STEAM RAILROADS COMMITTEE

To study all steam railroad electrifications in a general way, developing the fundamental reasons for, and the results of, these electrifications; to promote cooperation between the executives of railway and power companies for the mutual understanding of each other's problems

Officers

Chairman, Britton I Budd, Public Service Co of Northern Illino Chicago, Ill
Secretary, Horace H Field, Public Service Co of Northern Illinoi Chicago, Ill

Steam Railroads

Reinier Beeuwkes, Chicago, Milwaukee, St Paul & Pacific Railroad Co, Seattle, Wash
E P Bracken, Chicago, Burlington & Quincy Railroad Co, Chicago, Ill
D J Brumley, Illinois Central Railroad Co, Chicago, Ill
Ralph Budd, Great Northern Railway Co, St Paul, Minn
H A Currie, New York Central Railroad Co, New York, N Y
G W Hand, Chicago & NorthWestern Railway Co, Chicago, Ill
H A Johnson, Chicago Rapid Transit Co, Chicago, Ill

Subcommittee on Electrification in Europe

Chairman, H A Johnson; *Secretary,* Horace H Field; Reinier Beeuwkes, L E Fischer

Subcommittee on Form of Contract

Chairman, E W Lloyd; *Secretary,* Horace H Field; C P Billings, D J Brumley, H J Dunbaugh, R B Grove, J T Wallis, L Wylie

EXHIBITION COMMITTEE

To take charge of exhibitions held in connection with conventions of the Association. This Committee is elected annually by Class "D" members

Chairman, E W Goldschmidt, Wagner Electric Corp, New York N Y

Secretary-Treasurer, Frank H Gale, General Electric Co, Schenectady, N Y
Edwin L Andrew, Rome Wire Co, Rome, N Y
S E Doane, National Lamp Works of G E Co, Cleveland, Ohio
E D Doty, Frigidaire Corp, Dayton, Ohio
J J Greene, Johns-Manville Corp, New York, N Y
George A Hughes, Edison Electric Appliance Co, Inc, Chicago, Ill
J C McQuiston, Westinghouse Electric & Manufacturing Co, East Pittsburgh, Pa
C L Peirce, Jr, Hubbard & Co, Pittsburgh, Pa

FINANCE COMMITTEE

To supervise the finances of the Association, reporting to the President and National Executive Committee

Chairman, Sidney Z Mitchell, Electric Bond & Share Co, New York, N Y
N F Brady, The New York Edison Co, New York, N Y
Henry L Doherty, Henry L Doherty & Co, New York, N Y
Charles L Edgar, The Edison Electric Illuminating Co, Boston, Mass
Samuel Insull, Commonwealth Edison Co, Chicago, Ill
J J O'Brien, H M Byllesby & Co, Chicago, Ill
P S Young, Public Service Electric & Gas Co, Newark, N J

LAMP COMMITTEE

To report to members current developments in the manufacture, the characteristics and utilization of incandescent, arc lamps and other electric illuminants and equipment in connection therewith; to secure the adoption of suitable standard lamp voltages; to report the current practices of the Member Companies with respect to the handling of incandescent lamps

Chairman, Frank W Smith, The United Electric Light & Power Co, New York, N Y
Secretary, Robert B Grove, The United Electric Light & Power Co, New York, N Y
W H Atkins, The Edison Electric Illuminating Company of Boston, Boston, Mass
Douglass Burnett, Consolidated Gas, Electric Light & Power Co, Baltimore, Md

Charles J Russell, The Philadelphia Electric Co, Philadelphia, Pa

Special Membership of Subcommittees

M D Cooper, National Lamp Works of G E Co, Cleveland, Ohio
Samuel G Hibben, Westinghouse Lamp Co, Bloomfield, N J
G S Merrill, National Lamp Works of G E Co, Cleveland, Ohio
Preston S Millar, Electrical Testing Laboratories, Inc, New York, N Y
Henry Schroeder, Edison Lamp Works of G E Co, Harrison, N J

Carbon Lamps and Their Uses Subcommittee

Chairman, S E Doane; S Ferguson, C J Russell

Preparation of Articles for N E L A Bulletin Subcommittee

Chairman, Preston S Millar; Samuel G Hibben, G S Merrill, Henry Schroeder

Standardization of Lamp Voltages Subcommittee

Chairman, S E Doane; M D Cooper, Samuel G Hibben, Preston S Millar, Henry Schroeder

PRIZE AWARDS COMMITTEE

This Committee shall be in charge of all the prize awards offered by the Association, with the exception of the Charles A Coffin Prize. It shall prepare the necessary leaflets and other means of notification to the Association's membership. It shall receive the reports and papers on the various awards and will make recommendations to the National Executive Committee covering its decision as to the winners in the various contests. With the exception of the Charles A Coffin Prize and the Insull Medals, the Committee will announce these awards at the Annual Convention

Chairman, W H Onken, Jr, *Electrical World,* New York, N Y
B C Forbes, *Forbes Magazine,* New York, N Y
John T Madden, New York University, New York, N Y
W S Murray, Murray & Flood, New York, N Y
Miss Clara Zillessen, The Philadelphia Electric Co, Philadelphia, Pa

PUBLIC POLICY COMMITTEE

To determine the policy of the Association on all questions of broad public import, to recommend to member companies such attitude and action in relation to specific questions as will best promote the welfare of the industry in the public service. Included in the personnel of the Committee are the President and four Vice-Presidents of the Association and four representatives from the Executive Committee of the Public Relations National Section

Chairman, R H Ballard, Southern California Edison Co, Los Angeles, Cal
Vice-Chairman, W W Freeman, Columbia Gas & Electric Corp, New York, N Y
P S Arkwright, Georgia Power Co, Atlanta, Ga
Henry G Bradlee, Stone & Webster, Inc, Boston, Mass

T A Kenney, Allied Power & Light Corp, New York, N Y
Guy W Talbott, Pacific Power & Light Co, Portland, Ore

RATE RESEARCH COMMITTEE

To publish information as to current rates and decisions bearing upon rates—in other words, the supervision of the publication of Rate Research and the Rate Book

To study and report to the Executive Committee (or Public Policy Committee) at intervals all new rate methods; rate methods being defined as the theory and construction of practical rate schedules

The coordination of work of other bureaus and committees of the Engineering, Commercial and Accounting Sections along lines which lead into questions of rate theory, this function to be developed to the elimination of duplicated work and the avoidance of inconsistent conclusions by committees of Sections working separately

Chairman, L R Nash, Stone & Webster, Inc, Boston, Mass
Secretary, C E Neil, The North American Co, New York, N Y
H H Agee, Public Service Electric & Gas Co, Newark, N J
E J Fowler, Commonwealth Edison Co, Chicago, Ill
John W Lieb, The New York Edison Co, New York, N Y
E N Strait, Byllesby Engineering & Management Corp, Chicago, Ill
W G Vincent, Jr, Pacific Gas & Electric Co, San Francisco, Cal
W R Waggoner, Alabama Power Co, Birmingham, Ala
Ralph P Wagner, Henry L Doherty & Co, New York, N Y

WATER POWER DEVELOPMENT COMMITTEE

To investigate and report upon the water power possibilities of the country, both developed and undeveloped, and suggest a broad policy for future development and interconnection of water-power systems

Chairman, PAUL A SCHOELLKOPF, The Niagara Falls Power Co, Niagara Falls, N Y
R H BALLARD, Southern California Edison Co, Los Angeles, Cal
H T EDGAR, Stone & Webster, Inc, Boston, Mass
H W FULLER, Byllesby Engineering & Management Corp, Chicago, Ill
D C GREEN, Utah Power & Light Co, Salt Lake City, Utah
H I HARRIMAN, New England Power Co, Boston, Mass
A W LEONARD, Puget Sound Power & Light Co, Seattle, Wash

Commercial National Section

Scope of Activity

The scope of activities of the Commercial National Section shall be to encourage commercial progress through teamwork between the branches of our industry and groups directly interested with the National Electric Light Association in electrical development; to analyze the commercial needs of the industry; to make surveys and plans for sales development, and to advance by all constructive means the use of electrical energy for light, heat and power for public service.

EXECUTIVE COMMITTEE

Officers

Chairman, Marshall E Sampsell, Central Illinois Public Service Co, Chicago, Ill

Vice-Chairman, Frank D Pembleton, Public Service Electric & Gas Co, Newark, N J

Vice-Chairman, T O Kennedy, The Ohio Public Service Co, Cleveland, Ohio

Vice-Chairman, V M F Tallman, Charles H Tenney & Co, Boston, Mass

STREET LIGHTING COMMITTEE

To place street lighting before the commercial executives of the central stations as a sales responsibility; to develop a street lighting sales plan to present to commercial managers so that this activity will receive the same aggressive sales efforts as other more familiar load building activities receive

Street lighting will be shown as key to development of entire lighting program of the central station. Study and survey will be made regarding street lighting practices in the various parts of the country with view in mind of presenting actual conditions in the various central stations so as to provide a guide to any utility contemplating street lighting promotion

Study will be made of highway lighting, reviewing what has been done and what should be done in future to develop this rural lighting program. Cooperation with other lighting committees to include street lighting in all lighting sales programs will be kept before the committee at all times

Chairman, H P Dilkes; A V Lindsley, L W Pratt

Sales Analysis Subcommittee

Chairman; Ell C Bennett; Earl Whitehorne

MERCHANDISE SALES COMMITTEE

To develop broader marketing plans and better trade relations; to analyze the market for load building appliances; to stimulate appliance sales through advertising and through cooperative marketing plans; to stimulate the sale of more kilowatt-hours; to study new fields of appliance selling, especially appliances for the farm, and power radio

Chairman, C L Harold, Brooklyn Edison Co, Inc, Brooklyn, N Y
A K Baylor, General Electric Co, New York, N Y
C O Dunton, Central & South West Utilities Co, Dallas, Tex
Harry C Hahn, Electric Vacuum Cleaner Co, Cleveland, Ohio
Thomas F Kelley, The Hoover Vacuum Cleaner Co, North Canton, Ohio
Harvey R Keys, Duquesne Light Co, Pittsburgh, Pa
C K Magers, The Union Gas & Electric Co, Cincinnati, Ohio
H J Mauger, Edison Electric Appliance Co, Chicago, Ill
M C Morrow, Westinghouse Electric & Manufacturing Co, Mansfield, Ohio
Grover C Neff, Wisconsin Power & Light Co, Madison, Miss
Ralph Neumuller, The United Electric Light & Power Co, New York, N Y
C E Nichols, The New York Edison Co, New York, N Y
G Ostlund, Westchester Lighting Co, Mt Vernon, N Y
H A Pendergraph, Georgia Power Co, Atlanta, Ga
Dorsey Smith, Consolidated Gas, Electric Light & Power Co, Baltimore, Md
C V Sorensen, Attica Electric Co, Attica, Ind
J S Sutherland, Alabama Power Co, Birmingham, Ala
Stanley Taber, Iowa-Nebraska Light & Power Co, Lincoln, Neb
H D Valentine, Central Hudson Gas & Electric Co, Poughkeepsie, N Y
J H Van Aernam, New York Power & Light Corp, Albany, N Y
C P Wagner, Northern States Power Co, Minneapolis, Minn
Frank W Watts, *Electric Light & Power,* New York, N Y
Earl Whitehorne, *Electrical World,* New York, N Y
H E Young, Northern States Power Co, Minneapolis, Minn
Miss Clara H Zillessen, The Philadelphia Electric Co, Philadelphia, Pa

Advertising Subcommittee

Chairman, Earl Whitehorne; C K Magers, H J Mauger, Ralph Neumuller, H D Valentine, Miss Clara H Zillessen

Atlantic City Exhibit Subcommittee

Chairman, H D Valentine; A K Baylor, Ralph Neumuller, Earl Whitehorne

Farm Equipment Sales Subcommittee

Chairman, Grove C Neff; H A Pendergraph, C V Sorensen, Stanley Taber, C P Wagner

Oil Burners Subcommittee

Chairman, A K Baylor; C E Nichols, H D Valentine, H E Young

K.W.H. Contest Prizes Subcommittee

Chairman, C L Harold; A K Baylor, M C Morrow, Earl Whitehorne

Quality Standards Subcommittee

Chairman, H D Valentine

Radio Subcommittee

Chairman, J H Van Aernam; C O Dunton, Harvey R Keys, Dorsey Smith, J S Sutherland

REFRIGERATION COMMITTEE

To develop plans for promoting the electric refrigeration load, and to devise sales plans; to cooperate with the manufacturers of refrigeration equipment in broad plans to sell the need of food preservation for health and economy, culminating this effort in national educational activity

Chairman, C L Dunn, The Ohio Public Service Co, Cleveland, Ohio
Cyrus Barnes, Charles H Tenney & Co, Boston, Mass
G B Buck, Public Service Co of Colorado, Denver, Colo
W E Clement, New Orleans Public Service Inc, New Orleans, La
J A Corcoran, Kelvinator Detroit Co, Detroit, Mich
Mrs Cecil Harvey, Westchester Lighting Co, Mt Vernon, N Y
Henry W Hennig, Public Service Co of New Jersey, Newark, N J
T P Kindig, *Electrical World* New York, N Y
P Lorch, The New York Edison Co, New York, N Y
J E North, Electrical League, Cleveland, Ohio
George A Stewart, Interstate Public Service Co, Indianapolis, Ind
Stanley Taber, Iowa-Nebraska Light & Power Co, Lincoln, Neb
M C Terry, Westinghouse Electric & Manufacturing Co, Mansfield, Ohio
J Hall Truman, Stevens & Wood, Inc, New York, N Y
Earl Whitehorne, *Electrical World,* New York, N Y
W R Winans, Frigidaire Corp, New York, N Y
H E Young, Northern States Power Co, Minneapolis, Minn
P B Zimmerman, General Electric Co, Cleveland, Ohio

Educational Plan Subcommittee

Chairman, J Hall Truman; J A Corcoran, Earl Whitehorne

WATER HEATING COMMITTEE

To conduct a comprehensive survey of apparatus available; to make field tests of the many practices of water heating methods now in use with the idea of determining the best methods of water heating installations; to study load characteristics of electric water heating, and to ascertain and recommend practical methods of developing potential load

Chairman, Norman T Wilcox, Stone & Webster, Inc, Boston, Mass
M T Crawford, Puget Sound Power & Light Co, Seattle, Wash
J F Derge, Florida Power & Light Co, Miami, Fla
C J Eaton, Middle West Utilities Co, Chicago, Ill
W E Goring, Dominion Power & Transmission Co, Ltd, Hamilton, Can
R S Hale, Edison Electric Illuminating Company of Boston, Boston, Mass
A V Jones, Buffalo General Electric Co, Buffalo, N Y
J C Langdell, Consumers Power Co, Jackson, Mich
W H McInnis, Columbus Power & Light Co, Columbus, Ga
W C McWhinney, Southern California Edison Co, Los Angeles, Cal
Earl Nichols, Iowa Railway & Light Co, Cedar Rapids, Iowa
George D Nutting, Edison Electric Illuminating Co, Detroit, Mich
H C Wilder, Rome Wire Co, Rome, N Y

CUSTOMER RELATIONS COMMITTEE

To promote good-will and improve the relationship between electric light and power companies and their customers by formulating efficient methods for handling customer contacts. The Committee's work covers all practices and policies which influence the attitude of the customer toward the company, such as application procedures, simplification of methods, improvement of forms, development of routines, handling of inquiries and complaints, meter reading, collections and credits, telephone and correspondence communications and general improvement of service

To prepare monthly reports on customer relations subjects for publication in the N E L A Monthly Bulletin under the title "Service Suggestions"

To cooperate with all other Committees in the promotion of good-will

Chairman, H T East, Public Service Co of Northern Illinois, Chicago, Ill
Vice-Chairman, J G Ross, The Rochester Gas & Electric Corp, Rochester, N Y

Members at Large

R F Bonsall, Consolidated Gas, Electric Light & Power Co, Baltimore, Md
Miss Marguerite Butler, Portland Electric Power Co, Portland, Ore
J W De Maine, Northern States Power Co, Minneapolis, Minn
G J Leibman, Brooklyn Edison Co, Inc, Brooklyn, N Y
C E Michel, Union Electric Light & Power Co, St Louis, Mo
X J Montreuil, New York & Queens Electric Light & Power Co, Long Island City, N Y
H L Nickerson, Southwestern Gas & Electric Co, Shreveport, La
H L Oulliber, New Orleans Public Service Co, Inc, New Orleans, La
H M Pace, South Carolina Power Co, Charleston, S C
Paul Renshaw, Memphis Power & Light Co, Memphis, Tenn
Louis Stoecker, Public Service Electric & Gas Co, Newark, N J
P G Vondersmith, The Union Gas & Electric Co, Cincinnati, Ohio
Harold Wright, Commonwealth Edison Co, Chicago, Ill

Geographic Division Representatives

Canadian—
Eastern—H W Ewald, Electrical League of Pittsburgh, Pittsburgh, Pa
East Central—H N Wood, Pennsylvania-Ohio Power & Light Co, Youngstown, Ohio
Great Lakes—L M LaPorte, Milwaukee Electric Railway & Light Co, Milwaukee, Wis
Middle West—E J Otterbein, Peoples Light Co, Davenport, Iowa
New England—Ralph H Wheelock, Narragansett Electric Co, Providence, R I
North Central—R A Bearnes, Interstate Power Co, Albert Lea, Minn
Northwest—W A Schoel, Puget Sound Power & Light Co, Everett, Wash
Pacific Coast—Ward C Schafer, Pacific Gas & Electric Co, Stockton, Cal
Rocky Mountain—Ralph W Booze, Colorado Central Power Co, Golden, Colo
Southeastern—Frank R Mitchell, Georgia Power Co, Atlanta, Ga
Southwestern—T H Williams, Texas Power & Light Co, Waco, Tex

PROMOTIONAL RATES COMMITTEE

To review rate forms that may be developed in different power companies established for domestic service, and to urge the adoption of "promotional" forms which will be of benefit to the public and the company in selling greater electric service

Chairman, E W Lloyd, Commonwealth Edison Co, Chicago, Ill
A K Baylor, General Electric Co, New York, N Y
Robert S Hale, The Edison Electric Illuminating Co, Boston, Mass
Thomas F Kennedy, Henry L Doherty & Co, New York, N Y
F E Kruesi, Middle West Utilities Co, Chicago, Ill
Miss Sarah Sheridan, The Detroit Edison Co, Detroit, Mich

WIRING SALES COMMITTEE

To promote sales activity directed toward adequate wiring installations; to develop wiring materials and methods of wiring; to watch wiring developments for needed revisions of the National Electrical Code

Chairman, A P Good, Commonwealth Edison Co, Chicago, Ill
Vice-Chairman, J D Noyes, The Detroit Edison Co, Detroit, Mich
L L Bailey, West Penn Power Co, Pittsburgh, Pa
E A Brand, New York Power & Light Corp, Albany, N Y
J W Cowles, The Edison Electric Illuminating Co, Boston, Mass
M C Huse, The Philadelphia Electric Co, Philadelphia, Pa
G E Miller, The Cleveland Electric Illuminating Co, Cleveland, Ohio
Ralph Neumueller, The United Electric Light & Power Co, New York, N Y
Walter Sturrock, National Lamp Works of G E Co, Nela Park, Cleveland, Ohio

Geographic Division Representatives

Canadian—J K Wilson, The Shawinigan Water & Power Co, Montreal, Can
Eastern—L L Bailey, West Penn Power Co, Pittsburgh, Pa
East Central—G E Miller, The Cleveland Electric Illuminating Co, Cleveland, Ohio

Rocky Mountain—Luke Storey, Home Gas & Electric Co, Greeley, Colo
Southeastern—W W Barr, Georgia Power Co, Dublin, Ga
Southwestern—J O Bannahan, Houston Lighting & Power Co, Houston, Tex

Contact Member for Commercial National Section

L B Bonnett, Brooklyn Edison Co, Brooklyn, N Y

Contact Member for Commercial and Industrial Lighting Committee

E A Brand, New York Power and Light Corp, Albany, N Y

Contact Member for Merchandise Sales Committee

Earl Whitehorne, *Electrical World,* New York, N Y

Metropolitan Area, New York City, Member-at-Large

L A Scofield, The United Electric Light and Power Co, New York, N Y

Revision of National Electrical Code Subcommittee

To study the Code for needed changes; to compile data which would support definite proposals to change the Code; to examine proposals of other organizations for changes in the Code and to prepare in advance data supporting or opposing such proposed changes according as they prove to be for or against the Subcommittee's conception of the interest of the electrical industry

Chairman, A P Good

Wiring Sales Promotion Subcommittee

To promote sales activity directed toward adequate wiring installations

Chairman, E A Brand; L L Bailey, Ralph Neumueller, Walter Sturrock

Wiring Materials and Methods Subcommittee

To develop methods of wiring; to study, develop and test wiring materials, flexible cords, etc

Chairman, John D Noyes; J W Cowles, A P Good, M C Huse, G E Miller

Engineering National Section

Scope of Activity

The Section deals with all engineering matters. Its major purposes are:

(a) To accelerate the development of the art through studies of important engineering problems and interchange of ideas. (b) To keep engineers informed as to the latest and best developments and operating practices in power system engineering by providing opportunity for discussion of their problems and by the compiling and distribution of serial reports of important engineering developments and practices. (c) To set up authoritative engineering policies for the industry in matters dealing with codes and standards, joint construction with other utilities and all subjects in which engineering contact is had with other interests.

The work of the Section is handled by Committees whose activities include the following:

To investigate and report tendencies and developments in design, installation and operation of and experience with electric power systems and the apparatus and equipment used in connection therewith. To study intensively the problems of electric power generation, transmission and distribution to encourage constructive efforts by member companies in the form of investigations, tests and other suitable means to better understand the conditions to which power systems and their apparatus are subjected in service. To ascertain the requirements of the industry concerning apparatus to be used and to see that the manufacturers are thoroughly informed as to such requirements. To follow through appropriate cross-representation the work of other committees of this Association which is of interest to the Section, with a view to coordinating such work. To follow codification and standardization work particularly with the bodies engaged in the actual formulation of standards; to maintain a suitable committee policy for dealing with the technical subject matter of standards, and when appropriate, to initiate activities in connection with such subjects when these are deemed necessary to properly protect and promote the best interests of the industry. To provide representation as deemed desirable and proper from time to time on committees of other organizations working within the field of this Section, in order to properly protect the interests of the industry.

At the present time the work of the Section is directed toward the following major objectives:

More kilowatts of system capacity per dollar of investment. Definite advance planning of system development, and coordination of adjacent systems. Comprehensive research in fundamental engineering problems of the industry, coordinated through the committees. Recruiting and training of adequate engineering personnel. Better content and wider distribution of serial reports. Study of and, when desirable, reports on national engineering issues affecting our industry. Constructive cooperation in the national movement for standardization. Greater engineering service to the industry through closer cooperation with other Sections and Committees.

EXECUTIVE COMMITTEE

Officers

Chairman, E C Stone, Duquesne Light Co, Pittsburgh, Pa
Vice-Chairman, Thomas Sproule, Public Service Electric & Gas Co, Newark, N J
Vice-Chairman, A D Bailey, Commonwealth Edison Co, Chicago, Ill
Vice-Chairman, Nicholas Stahl, Pennsylvania Power & Light Co, Allentown, Pa

Members at Large

(Terms expiring June 30, 1929)

C F Hirshfeld, *Ex-officio,* The Detroit Edison Co, Detroit, Mich
H L Doolittle, Southern California Edison Co, Los Angeles, Cal
K R MacKinnon, Nebraska Power Co, Omaha, Neb
W E Mitchell, Georgia Power Co, Atlanta, Ga

(Terms expiring June 30, 1930)

C M Allen, Worcester Polytechnic Institute, Worcester, Mass
C L Lefever, Northwestern Electric Co, Portland, Ore
H R Woodrow, Brooklyn Edison Co, Inc, Brooklyn, N Y

Geographic Division Representatives

Canadian—C V Christie, McGill University, Montreal, Can
Eastern—C H Frick, Pennsylvania Power & Light Co, Allentown, Pa
East Central—Wm Shuler, The Dayton Power & Light Co, Dayton, Ohio
Great Lakes—F E Andrews, Public Service Co of Northern Illinois, Chicago, Ill
Middle West—C L Karr, Kansas Gas & Electric Co, Wichita, Kan
New England—C A Mayo, Malden Electric Co, Malden, Mass
North Central—J A Colvin, Northern States Power Co, Minneapolis, Minn
Northwest—D W Proebstel, Portland Electric Power Co, Portland, Ore
Pacific Coast—N B Hinson, Southern California Edison Co, Los Angeles, Cal
Rocky Mountain—P S Schools, Western Colorado Power Co, Durango, Colo
Southeastern—H J Scholz, Alabama Power Co, Birmingham, Ala
Southwestern—R F Danner, Oklahoma Gas & Electric Co, Oklahoma City, Okla

Committee Chairmen

Accident Prevention Committee
C R Beardsley, Brooklyn Edison Co, Inc, Brooklyn, N Y

Electrical Apparatus Committee
J A Johnson, The Niagara Falls Power Co, Niagara Falls, N Y

Engineering Administration Committee

Pacific Coast—F S Thomas, Coast Counties Gas & Electric Co, Gilroy, Cal
Rocky Mountain—Charles F Dwyer, Public Service Co of Colorado, Denver, Colo
Southeastern—R B Grove, Florida Power & Light Co, Miami, Fla
Southwestern—H E Braunig, Gulf States Utilities Co, Beaumont, Tex

Manufacturers' Representatives

C B Auel, Westinghouse Electric & Manufacturing Co, Pittsburgh, Pa
G E Sanford, General Electric Co, Schenectady, N Y

Engineering Committee Representatives

Electrical Apparatus Committee
A H Sweetnam, The Edison Electric Illuminating Co, Boston, Mass

Meter Committee
A J Allen, The United Electric Light & Power Co, New York N Y

Overhead Systems Committee
W C Wagner, The Philadelphia Electric Co, Philadelphia, Pa

Underground Systems Committee
E W Oesterreich, Duquesne Light Co, Pittsburgh, Pa

Automobile Accidents Subcommittee

To investigate causes and results of automobile accidents to employees and cars of member companies. To recommend methods of selection and training of drivers

Chairman, W E Sanford; George S Diehl, J R Grant, A J Van Brunt

Codes Subcommittee

To scan proposed codes with reference to accident prevention provisions, and report such provisions in advance of their adoption

Chairman, W C Wagner; Dennis L Boyle, H D Freitag, M L Wilkins

Construction Subcommittee

To study construction methods and develop safe practices

Chairman, M R Sumner; W H Brown, A G Butler, M O Howle, A W Lee, W R Loyd, K R MacKinnon, C C Steck

Contests Subcommittee

To study contests and prepare recommendations for rules, scope, methods of judgment and award

Chairman, F A Belden; M H Bowman, Jr, R B Grove, P L G Hasskarl, P R Kuhn, Buford McCulloch

Cooperation with National Safety Council Subcommittee

To study division of work; to effect mutual cooperation and exchange of information; to prevent duplication of effort

Chairman, C J Rutland; M H Bowman, Jr, W A Buchanan, W R Loyd, K R MacKinnon, Buford McCulloch, H F Webb

Cost of Accidents Subcommittee

To study overall costs of accidents

Chairman, F S Thomas; M H Bowman, Jr, J B Fisken, M F Treadwell, F T Wendell

Fire Prevention and Extinguishment Subcommittee

(Personnel being determined)

Geographic Divisions Subcommittee

To stimulate work in all Geographic Divisions; prepare bibliography of divisions' reports; distribute important reports; promote use of all Accident Prevention Committee, N E L A publications

Chairman, W A Buchanan; J R Grant, Perry Mellon, R M Moore, I L Scott

Grounding Subcommittee

To review Accident Prevention Committee Report, "Temporary Grounding" No 278-4

Chairman, P L G Hasskarl; Charles F Dwyer, P R Kuhn, R M Moore, M F Treadwell

Handbook on Safety Training Subcommittee

To outline essential features of selecting and training employees for safety

Chairman, C J Rutland; M H Bowman, Jr, W H Brown, J R Grant, H H Judson, H M Keller, Miss Elizabeth Lee, H F Lovering, R M Moore

High Voltage Testing Subcommittee

To study high voltage testing and develop safe practices

Chairman, C C Steck; J R Grant, H H Judson, George Opp

Hot Line Tools Subcommittee

To study hot line tools; to develop safe practices; to secure preparation of purchase and test specifications for tools; to prepare recommendations for working rules (conferring with related committees)

Chairman, H E Braunig; W A Buchanan, Paul A Carnahan, Charles F Dwyer, P L G Hasskarl, A W Lee, H F Lovering, K R MacKinnon, H E Shedd

Low Voltage Hazards Subcommittee

To study low voltage hazards and accidents and prepare educational matter

Chairman, E W Gorry; F A Belden, Miss Elizabeth Lee, Miss Helen Smith, R C Sogge

Resuscitation and First Aid Subcommittee

To study resuscitation and first aid; prepare educational matter

Chairman, Wills Maclachlan; J B Fisken, E W Gorry, J P Jackson, A J Van Brunt

Insull Medal Award Sub Subcommittee

To administer Insull Medal Award for N E L A

Chairman, Wills Maclachlan; E W Gorry, A J Van Brunt

Rubber Gloves and Goods Subcommittee

To report on manufacture, shipment and storage, purchase specifications, retests, field use of rubber gloves and goods

Chairman, K R MacKinnon; A J Allen, E W Oesterreich, A H Sweetnam, W C Wagner

Safety Provisions, Devices and Appliances Subcommittee

To review safety features of devices referred to Accident Prevention Committee; to list safety features, designs and apparatus; to promote their use

Chairman, C C Steck; C B Auel, M Eldredge, R B Grove, Buford McCulloch, G E Sanford, F S Thomas, A J Van Brunt, F T Wendell

Statistics Subcommittee

To supervise collection of accident statistics; to make annual analysis and report

Chairman, W R Loyd; M H Bowman, Jr, J P Jackson, H F Lovering, Mrs Grace D Thweatt

Suggestion Systems Subcommittee

To study suggestion systems

Chairman, C B Auel; H H Judson, H M Keller, George Opp, M F Treadwell

Unusual Accidents Subcommittee

To study unusual accidents and recommend protection against new hazards

Chairman, I L Scott; H F Lovering, F T Wendell

ELECTRICAL APPARATUS COMMITTEE

The scope of this Committee includes consideration of the design, characteristics, disposition, use or operation, and maintenance of all electrical generation, transformation, conversion, utilization, control, protective and communication apparatus required or used in connection with electric power systems when located in power stations, in substations or on users' premises, from the coupling of the prime mover in the generating station to the point of utilization of the power, including the design of generating station and substation buildings, structures, circuits and devices for the housing, support, connection, operation and manipulation of such apparatus

Officers

Chairman, J Allen Johnson, The Niagara Falls Power Co, Niagara Falls, N Y
Vice-Chairman, R A Hentz, The Philadelphia Electric Co, Philadelphia, Pa
Secretary, G Sutherland, New York & Queens Electric Light & Power Co, Long Island City, N Y

Counsellors

INDUCTIVE COORDINATION COMMITTEE

The major functions of this Committee are. To study conditions and current practices, both foreign and domestic, relating to the inductive coordination of power and signal systems; to further a better understanding of inductive coordination and encouraging cooperative planning for the coordination of facilities; to formulate principles and preferred practices as guides for the inductive coordination of power and signal systems; to consult with member N E L A companies for the purpose of rendering assistance in their inductive coordination problems; to keep in touch with and advise in the matter of local activities affecting or liable to affect the inductive coordination situation through legislation, commission regulations or rulings, contractual relations, or intercompany practices; to aid in joint studies with other interests concerned with, or aimed toward, the formation of working rules and specifications to govern the installation and coordination of the respective services; to prepare educational courses for the information and training of power system engineers in the principles and practices of inductive coordination

METER COMMITTEE

The scope of this Committee includes consideration of the design, installation, test, operation and maintenance of electrical metering and measuring devices as used on customers' premises, in industrial substations and in company generating and substations and of electrical and time measuring instruments and devices as used in the laboratory or in the field, including indicating, recording and graphic meters, primary and secondary electrical standards, standard clocks, timing relays, stop watches and other laboratory instruments used for standardization

Special functions of this Committee include: Analysis of existing rules and regulations of Federal, State or local regulatory bodies and the preparation and consideration of new rules and methods of procedure for the maintenance of meters and meter installations; preparation of educational courses for the training and development of men for service in the meter departments of operating companies

Chairman, Edward Hansson; *Vice-Chairman,* M E Grah; E K Alberts, F C Arthur, R G Boyles, E W Cole, E M Conwell, A E Davison, Frank Howard, L B Johnson, R W Mavity, J T Persons, T A Purton, G J Roewe, George Templeman

Steel Tower Transmission Lines Sub Subcommittee

Chairman, L O Waite; C A Bacon, E S Bundy, R N Conwell, W E Gundlach, H O Hill, J P Jollyman, J L T Martin, H Michener, D A Pierce, H D Pierce, C A Powel, L O Prescott, F H Taylor, S N Watt, T A Worcester

Wood Pole Transmission Sub Subcommittee

Chairman, A N Cartwright; Paul P Ashworth, W B Flynn, R H Halpenny, J K Himes, E J Kallevang, N T Kinzley, M M Koch, D A Pierce, R C Vickers

Loading and Strength of Overhead Lines Subcommittee

Chairman, W G Kelley; *Vice-Chairman,* W C Wagner; R R Cowles, F F Fowle, H H Schoolfield, H C Sutton

Railroad Wire Crossings Subcommittee

Chairman, J C Martin; P H Chase, R N Conwell, A E Silver

POWER SYSTEMS ENGINEERING COMMITTEE

To study the coordination of the fundamental elements in a power system in order to provide a guide for building and operating a system on the best and most economical basis

To study trends in system design and operation in order to afford guides for developing the existing systems along the best possible lines

All the work of the Committee is approached from the system point of view and is directed toward tangible guides that executives may use. An economic basis of evaluation of all developments is used and principles are accented rather than details. Specified studies under way are load surveys and load forecasts, distribution for high load density areas, principles of interconnection, utility energy supply to electrification projects, system layout principles and the formulation of a fundamental system building plan

Officers

Chairman, L W W Morrow, *Electrical World,* New York, N Y
Secretary, S M Dean, The Detroit Edison Co, Detroit, Mich

Counsellors

P M Downing, Pacific Gas & Electric Co, San Francisco, Cal

Chairman, H W Eales; A E Bettis, J C Martin, J M Oliver, H R Searing, H R Summerhayes

PRIME MOVERS COMMITTEE

The scope of this Committee includes consideration of the design, characteristics, disposition, use or operation, and maintenance of all mechanical apparatus and equipment required or used in the production of steam from coal or any other source of energy than water from the fuel receiving plant to the coupling with the electric generator, and of buildings, structures and auxiliary apparatus and devices required or used in connection therewith. It also includes consideration of the fuels used and their characteristics

Public Relations National Section

Scope of Activity

The Public Relations National Section is organized for and devoted to the purpose of encouraging member companies to disseminate information that will give their employes and the public an understanding of the problems involved in the financing of electric light and power companies, and the furnishing, at fair rates, of continuous, dependable electric service. Its major purposes are:

To encourage member companies in so developing and training members of their organizations that employes will be able to interpret the industry to its customers and the public;
To act as a clearing house through which such ideas and practices as are found helpful in one company or section of the country may be made available to all;

To bring about and maintain a ready acceptance by the public of sound securities issued by the industry:

To be prepared, through study and research, to furnish accurate information on national problems mutually affecting the industry and the public;

To foster and develop cooperative work with legitimate agencies for the dissemination of such information, to the end that friction born of misunderstanding or misrepresentation shall be eliminated and the stability of the electrical industry be maintained.

EXECUTIVE COMMITTEE

Officers

Chairman, J F Owens, Oklahoma Gas & Electric Co, Oklahoma City, Okla
Vice-Chairman, E A Barrows, The Narragansett Electric Co, Providence, R I
Vice-Chairman, Leavitt Edgar, The Edison Electric Illuminating Co, Boston, Mass
Vice-Chairman, D C Green, Utah Power & Light Co, Salt Lake City, Utah

Members at Large

(Terms expiring June 30, 1929)

W A Jones, *ex-officio,* Henry L Doherty & Co, New York, N Y
T A Kenney, Allied Power & Light Corp, New York, N Y
Charles Penrose, Day & Zimmermann, Inc, Philadelphia, Pa
Guy W Talbot, Pacific Power & Light Co, Portland, Ore

(Terms expiring June 30, 1930)

V L Board, Public Service Co of Colorado, Denver, Colo
Clarence L Law, The New York Edison Co, New York, N Y

COOPERATION WITH EDUCATIONAL INSTITUTIONS COMMITTEE

To bring about a closer understanding, and better methods, of education with reference to public utilities in the higher institutions of learning

Chairman, Carl D Jackson, 36 West 44th Street, New York, N Y
W J Bizzell, Oklahoma State University, Norman, Okla
James C Bonbright, Columbia University, New York, N Y
Everett N Case, General Electric Co, New York, N Y
W E Cox, University of Washington, Seattle, Wash
T D Crocker, Northern States Power Co, Minneapolis, Minn
Richard T Ely, Institute of Land and Public Utility Economics, Chicago, Ill
John F Gilchrist, Commonwealth Edison Co, Chicago, Ill
Horace M Gray, University of Illinois, Urbana, Ill
George H Harries, H M Byllesby & Co, Chicago, Ill
Ralph Heilman, Northwestern University, Chicago Ill
Fred R Jenkins, Commonwealth Edison Co, Chicago, Ill
Eliot Jones, Stanford University, Palo Alto, Cal
George R Jones, Public Service Co of Northern Illinois, Chicago, Ill
Miss Elizabeth Lee, Alabama Power Co, Birmingham, Ala
Charles A Lory, State Agricultural College, Fort Collins, Colo
John T Madden, New York University, New York, N Y
Deane W Malott, Harvard University, Cambridge, Mass
L C Marshall, University of Chicago, Chicago Ill
Anson Marston, Iowa State College, Ames, Iowa
L R Nash, Stone & Webster, Inc, Boston, Mass
Miss Helen Norris, Commonwealth Edison Co, Chicago, Ill
J F Owens, Oklahoma Gas & Electric Co, Oklahoma City, Okla
A E Patten, Public Service Co of Northern Illinois, Chicago, Ill
C O Ruggles, Harvard Graduate School of Business Administration, Boston, Mass
I L Scharfman, University of Michigan, Ann Arbor, Mich
C F Scott, Yale University, New Haven, Conn
Henry L Trumbower, University of Wisconsin, Madison, Wis
W S Vivian, Middle West Utilities Co, Chicago, Ill

Geographic Division Representatives

Canadian—J K Wilson, The Shawinigan Water & Power Co, Montreal, Can
Eastern—W F Baum, Duquesne Light Co, Pittsburgh, Pa
East Central—D J Hard, The Cleveland Light & Power Co, Cleveland, Ohio
Great Lakes—Harold T Geisse, Wisconsin Valley Electric Co, Wausau, Wis
Middle West—C N Chubb, Iowa-Nebraska Light & Power Co, Lincoln, Neb
New England—E S Mansfield, The Edison Electric Illuminating Co, Boston, Mass
North Central—S H Conkey, Northern States Power Co, Minneapolis, Minn
Northwest—W P Strandborg, Portland Electric Power Co, Portland, Ore
Pacific Coast—A H Markwart, Pacific Gas & Electric Co, San Francisco, Cal
Rocky Mountain—H S Sands, First National Bank Building, Denver, Colo
Southeastern—R H Mangum, Alabama Power Co, Birmingham, Ala
Southwestern—H M Blain, New Orleans Public Service Inc, New Orleans, La

CUSTOMER OWNERSHIP COMMITTEE

To assist and encourage electric light and power companies in the policy of selling securities to customers; to suggest and encourage the continued adherence to the ten cardinal principles adopted by the Committee concerning the issuing and selling of securities; to accumulate data and compile statistics on the method and sale of securities by the member companies

Chairman, W H Hodge, Byllesby Engineering & Management Corp, Chicago, Ill
A S Cummins, H M Byllesby & Co, Chicago, Ill
John F Gilchrist, Commonwealth Edison Co, Chicago, Ill
Philip G Gossler, Columbia Gas & Electric Corp, New York, N Y
F L Greenhouse, Southern California Edison Co, Los Angeles, Cal
C M Hamilton, Electric Bond & Share Co, New York, N Y
Henry R Hayes, Stone & Webster & Blodgett, New York, N Y
A F Hockenbeamer, Pacific Gas & Electric Co, San Francisco, Cal
W A Jones, Henry L Doherty & Co, New York, N Y
Thomas W Martin, Alabama Power Co, Birmingham, Ala
Donald C McClure, Central Public Service Corp, Chicago, Ill
Robert Montgomery, Louisville Gas & Electric Co, Louisville, Ky
Fred H Scheel, Utility Securities Co, Chicago, Ill
A Emory Wishon, San Joaquin Light & Power Corp, Fresno, Cal

Geographic Division Representatives

Canadian—Fraser S Keith, The Shawinigan Water & Power Co, Montreal, Can
Eastern—J E Shute, Penn Central Light & Power Co, Altoona, Pa
East Central—J P Everett, The Toledo Edison Co, Toledo, Ohio
Great Lakes—D E Callender, Milwaukee Gas & Electric Co, Racine, Wis
Middle West—W C Blanchard, Kansas Electric Power Co, Lawrence, Kan
New England—R Howarth Twin State Gas & Electric Co, Boston, Mass
North Central—R M Howard, Mississippi Valley Public Service Co, Winona, Minn
Northwest—E G Jarvis, Portland Electric Power Co, Portland, Ore
Pacific Coast—S E Seaver, Los Angeles Gas & Electric Corp, Los Angeles, Cal
Rocky Mountain—Guy W Faller, Public Service Co of Colorado, Denver, Colo
Southeastern—F H Martin, Georgia Power Co, Atlanta, Ga
Southwestern—Mrs Ruth Steinhauser, Texas-Louisiana Power Co, Fort Worth, Tex

INFORMATION BUREAU ORGANIZATIONS COMMITTEE

To have general direction of the organization of information committees and to cooperate with all existing committees

Chairman, T A Kenney, Allied Power & Light Co, New York, N Y
T D Crocker, Northern States Power Co, Minneapolis, Minn
H T Edgar, Stone & Webster, Inc, Boston, Mass
Halford Erickson, Byllesby Engineering & Management Corp, Chicago, Ill
E W Hodges, Henry L Doherty & Co, New York, N Y
Martin J Insull, Middle West Utilities Co, Chicago, Ill
A B West, Southern Sierras Power Co, Riverside, Cal

Geographic Division Representatives

Canadian—
Eastern—Owen Kraft, Philadelphia Co, Pittsburgh, Pa
East Central—
Great Lakes—Tom C Polk, 910 Marquette Bldg, Chicago, Ill
Middle West—F J Hanlon, Peoples Gas & Electric Co, Mason City, Iowa
New England—S T MacQuarrie, 24 Milk St, Boston, Mass
North Central—W S Robertson, Minnesota Power & Light Co, Duluth, Minn
Northwest—
Pacific Coast—
Rocky Mountain—Arthur Prager, Albuquerque Gas & Electric Co, Albuquerque, N M
Southeastern—J P Dick, Georgia Power Co, Atlanta, Ga
Southwestern—E F McKay, 1020 Petroleum Bldg, Oklahoma City, Okla

INDUSTRIAL RELATIONS COMMITTEE

To work for the attainment of mutual understanding and confidence between employers and employees, and to make available records of experience with plans and methods designed to accomplish such purposes

To foster, through the executives of member companies, the proper education of employees in the fundamental economic principles of the light and power business in the proper understanding of the interrelations of the public and the industry, and in the proper handling of complaints and courtesy to the public

To foster the activities of company employees' organizations

Chairman, Homer E Niesz, Commonwealth Edison Co, Chicago, Ill
Secretary, A B Gates, Commonwealth Edison Co, Chicago, Ill
J M Barry, Alabama Power Co, Birmingham, Ala
Harold B Bergen, Henry L Doherty & Co, New York, N Y
George A Davis, Oklahoma Gas & Electric Co, Oklahoma City, Okla
F M Dee, Jr, Indiana Electric Corp, Traction Terminal Bldg, Indianapolis, Ind
Robert B Grove, The United Electric Light & Power Co, New York, N Y
W B Hartshorne, Public Service Electric & Gas Co, Newark, N J
J P Jackson, The New York Edison Co, New York, N Y
Fred R Jenkins, Commonwealth Edison Co, Chicago, Ill
Wills MacLachlan, 2 East Bloor St, Toronto, Canada
W J MacPherson, Public Service Co of Northern Illinois, Chicago, Ill
Miss Sophia Malicki, Middle West Utilities Co, Chicago, Ill
E S McClelland, Sr, Westinghouse Electric & Manufacturing Co, East Pittsburgh, Pa
W F Persons, The Milwaukee Electric Railway & Light Co, Milwaukee, Wis
A A Potter, Purdue University, Lafayette, Ind
Charles B Scott, Bureau of Safety, Chicago, Ill
W S Vivian, Middle West Utilities Co, Chicago, Ill
H D Valentine, Central Hudson Gas & Electric Corp, Poughkeepsie, N Y

Geographic Division Representatives

Canadian—
Eastern—A M Boyd, Philadelphia Suburban-Counties Gas & Electric Co, Philadelphia, Pa
East Central—Frank W Funk, Pennsylvania-Ohio Power & Light Co, Youngstown, Ohio
Great Lakes—H H Adams, Northern Indiana Public Service Co, Hammond, Ind
Middle West—Glen Morris, Kansas City Power & Light Co, Kansas City, Mo
New England—H U Greene, Cambridge Electric Light Co, Cambridge, Mass
North Central—T T Parker, Northwest Public Service Co, Huron, S D
Northwest—E C Kiersted, Idaho Power Co, Boise, Idaho

Pacific Coast—Eugene McCann, Pacific Gas & Electric Co, San Francisco, Cal
Rocky Mountain—F F McCammon, Public Service Co of Colorado, Denver, Colo
Southeastern—Frank R Mitchell, Georgia Power Co, Atlanta, Ga
Southwestern—R C Coffy, Fort Smith Light & Traction Co, Fort Smith, Ark

MANUFACTURERS' ADVERTISING COMMITTEE

To formulate and put into practice a campaign whereby manufacturers of electrical machinery equipment and supplies shall devote a portion of their advertising space in popular and trade magazines to the publication of "good-will" advertising

This committee will work in close cooperation with the Publicity Department

Chairman, T J McManis, General Electric Co, Schenectady, N Y
E M Beach, Westinghouse Lamp Co, New York, N Y
Frank LeRoy Blanchard, Henry L Doherty & Co, New York, N Y
A S Fromm, The Union Metal Manufacturing Co, Canton, Ohio
H H Green, National Lamp Works of G E Co, Cleveland, Ohio
W A Grove, Edison Electric Appliance Co, Inc, Chicago, Ill
Earl Hoover, The Hoover Co, Chicago, Ill

P L Thomson, Western Electric Co, New York, N Y
F U Webster, The Cutler-Hammer Manufacturing Co, Milwaukee, Wis

PUBLIC SPEAKING COMMITTEE

To organize through the Geographic Divisions a bureau of public speakers, national in its scope, and dealing with subjects pertaining to the electric light and power industry

Chairman, W S Vivian, Middle West Utilities Co, Chicago, Ill
R V Bozell, Bonbright & Co, New York, N Y
Thorne Browne, 1527 Sharp Building, Lincoln, Neb
Mrs Elsie Carter, Oklahoma Gas & Electric Co, Oklahoma City, Okla
J Paul Clayton, Central Illinois Public Service Co, Springfield, Ill
C W Davis, Dallas Power & Light Co, Dallas, Tex
R E Haas, Columbia Engineering & Management Corp, New York, N Y
Miss Sara Harris, Utica Gas & Electric Co, Utica, N Y
Carl D Jackson, 36 West 44th Street, New York, N Y
Fred R Jenkins, Commonwealth Edison Co, Chicago, Ill
Clarence L Law, The New York Edison Co, New York, N Y
Homer Niesz, Commonwealth Edison Co, Chicago, Ill
Tom C Polk, 910 Marquette Bldg, Chicago, Ill
Mrs Jane Pratt, Alabama Power Co, Birmingham, Ala
Paul Renshaw, Memphis Power & Light Co, Memphis, Tenn
E H Sniffen, Westinghouse Electric & Manufacturing Co, New York, N Y
W P Strandborg, Portland Electric Power Co, Portland, Ore

Geographic Division Representatives

Canadian—A Monro Grier, Canadian Niagara Power Co, Niagara Falls, Can
Eastern—H S Metcalfe, West Penn Power Co, Pittsburgh, Pa
East Central—D L Gaskill, 603 Broadway, Greenville, Ohio
Great Lakes—A E Scott, Interstate Public Service Co, Indianapolis, Ind
Middle West—Worth Bates, Missouri Gas & Electric Service Co, Lexington, Mo.
New England—Louis D Gibbs, The Edison Electric Illuminating Co, Boston, Mass
North Central—G O House, Northern States Power Co, St Paul, Minn
Northwest—S E Skelley, Pacific Power & Light Co, Portland, Ore
Pacific Coast—M H Schnapp, General Electric Co, San Francisco, Cal
Rocky Mountain—C H Elliott, Public Service Co of Colorado, Denver, Colo
Southeastern—Guy P Newbern, 502 Cotton States Building, Nashville, Tenn
Southwestern—E E Armstrong, Mississippi Power Co, Gulfport, Miss

RELATIONS WITH FINANCIAL INSTITUTIONS COMMITTEE

To cooperate with bankers and others interested in developing a broader outlet for sound securities of the electric light and power industry, to the end that such securities shall be generally accepted as legal investments for savings banks and trust funds;

To encourage member company executives to keep all investment agencies informed as to plans, problems and policies of the industry

Chairman, A W Robertson, Westinghouse Electric & Manufacturing Co, Pittsburgh, Pa
R H Ballard, Southern California Edison Co, Los Angeles, Cal
Henry G Bradlee, Stone & Webster, Inc, Boston, Mass
J H Briggs, H M Byllesby & Co, Chicago, Ill
Charles L Edgar, The Edison Electric Illuminating Co, Boston, Mass
Philip G Gossler, Columbia Gas & Electric Corp, New York, N Y
Martin J Insull, Middle West Utilities Co, Chicago, Ill
W A Jones, Henry L Doherty & Co, New York, N Y

Northwest—W H Lines, Portland Electric Power Co, Portland, Ore
Pacific Coast—A F Hockenbeamer, Pacific Gas & Electric Co, San Francisco, Cal
Rocky Mountain—Harry Hughes, Public Service Co of Colorado, Denver, Colo
Southeastern—Joe H Gill, Florida Power & Light Co, Miami, Fla
Southwestern—H C Couch, Arkansas Power & Light Co, Pine Bluff, Ark

WOMEN'S COMMITTEE

To formulate and put into effect plans for the education of women of the industry on the fundamental economic principles of the electric light and power business, and the interdependence of the public and industry

Chairman, Miss Sophia Malicki, Middle West Utilities Co, Chicago, Ill
Secretary, Miss Isabell Davie, National Electric Light Association, New York, N Y

Members at Large

Miss Marguerite Butler, Portland Electric Power Co, Portland, Ore
Mrs Pearl Evans, National Electric Power Co, New York, N Y
Miss May Fletemeyer, Northern Indiana Public Service Co, Hammond, Ind
Miss Sara Harris, Utica Gas & Electric Co, Utica, N Y
Miss Elizabeth Lee, Alabama Power Co, Birmingham, Ala
Miss Mildred Nichols, Graybar Electric Co, Inc, New York, N Y
Miss Helen Norris, Commonwealth Edison Co, Chicago, Ill
Mrs Frances Rosenberg, Commonwealth Edison Co, Chicago, Ill
Mrs A C Taggart, The New York Edison Co, New York, N Y
Mrs Florence Tate, Central & South West Utilities Co, Dallas, Tex
Mrs Thelma Van Ness, Consumers Power Co, Jackson, Mich
Miss Mary K Walsh, The Washington Water Power Co, Spokane, Wash

Geographic Division Representatives

Canadian—Miss Florence Donkin, The Shawinigan Water & Power Co, Montreal, Can
Eastern—Miss Iva B Sellers, Pennsylvania Electric Co, Johnstown, Pa
East Central—Miss Esther Rockey, The Dayton Power & Light Co, Dayton, Ohio
Great Lakes—Miss Theresa Carroll, Central Illinois Public Service Co, Springfield, Ill
Middle West—Miss Betty Ewing, Kansas Power & Light Co, Topeka, Kan
New England—Miss Alice Baker, The Hartford Electric Light Co, Hartford, Conn
North Central—Mrs Mabel Wilson, Northern States Power Co, Minneapolis, Minn
Northwest—Mrs Nell Laws, Puget Sound Power & Light Co, Seattle, Wash
Pacific Coast—Mrs Ruth Creveling, San Diego Consolidated Gas & Electric Co, San Diego, Cal
Rocky Mountain—Miss Frances Ryder, Southern Colorado Power Co, Pueblo, Colo
Southeastern—Mrs Jane Pratt, Alabama Power Co, Birmingham, Ala
Southwestern—Miss Julie Pailet, New Orleans Public Service Inc, New Orleans, La

Home Service Subcommittee

To develop programs of home service activities; to assist in establishing home service departments

Chairman, Miss Ada Bessie Swann, Public Service Electric & Gas Co, Newark, N J

Manufacturers' Subcommittee

To develop cooperation between women of electric serving companies and of manufacturer companies toward accomplishment of the purpose of the program of the general Women's Committee

Chairman, Miss Frances Weedman, Edison Electric Appliance Co, Inc, Chicago, Ill

Principles and Practices in Codes and Standards Operations

Of Concern to N.E.L.A. Committees

The Codes and Standards Committee, with the approval of the National Executive Committee, has adopted for the guidance of all individuals representing the Association upon committees of standardizing bodies, or upon committees engaged in the actual formulation of standards or codes, the following general principles:

1. Codes and other collections of rules or regulations, when offered for promulgation as standards, may enunciate principles to which assent is given. They should contain a minimum of quantitative requirements. Detailed specifications are highly objectionable.
2. Pure engineering standards, whether for dimensions, quality or performance, are necessarily quantitative, but even these should preferably stress the principles involved and tend to avoid restrictive detail.
3. Due regard should be had for economy. The burden of representation is heavy in time and money, and in order to keep this within bounds effort should be made to guide standardizing activities into the smallest number of channels practicable, and otherwise to condense such activities.

The committee has also adopted certain practices stated in Serial Report No. 267-52 entitled "Principles and Practices in Codes and Standards Operations," dated April, 1927. The following statements are extracted from this report:

> "Representation to standardizing bodies shall be official and responsible to the Committee on Codes and Standards.
>
> "Representation to technical committees engaged in the actual preparation of codes and standards shall be official and responsible to the appropriate national technical or other committees of the N. E. L. A., these, in turn, being responsible to the Codes and Standards Committee for such activities.
>
> "Appointments of all official representatives shall be made by, and recorded in, Headquarters, N. E. L. A. They shall be made by the Secretary of the Association upon the recommendation of the Codes and Standards Committee, on behalf of the President of the Association. Reappointments, replacements and reliefs shall be effected in the same manner.
>
> "Representatives of all classes shall report actions taken by them, the status of their projects and recommendations, to the Codes and Standards Committee, and to their N. E. L. A. committee principals. It may be desirable to require routine periodical reports from certain classes of representatives."

Related Activities—Organizations Concerned

(Follows list of Representatives and Alternates [*Alternates shown in italics*] of the National Electric Light Association, serving on the unit of the organization indicated.)

STATE PUBLIC UTILITY INFORMATION BUREAUS

(Follows a list of State Public Utility Information Bureaus, the territory which they cover and their Chairmen and Directors, who are not exclusively representatives of the National Electric Light Association)

Arkansas Public Service Information Bureau
(Arkansas)

Chairman, W E Bann, Southwestern Gas & Electric Co, Texarkana, Ark
Director, Rex I Brown, 320 Boyle Building, Little Rock, Ark

Connecticut Committee on Public Service Information
(Connecticut)

Chairman, Samuel Ferguson, The Hartford Electric Light Co, Hartford, Conn
Executive Secretary, Clarence G Willard, 52 Whitney Avenue, New Haven, Conn

Florida Public Utilities Information Bureau
(Florida)

Chairman, E A Olsen, Florida Power Corp, St Petersburg, Fla
Director, R J Holly, Room 413, First National Bank Building, Sanford, Fla

Utilities Information Committee of Georgia
(Georgia)

Chairman, P S Arkwright, Georgia Power Co, Atlanta, Ga
Executive Secretary, Willard Cope, 302-303 Haas-Howell Building, Atlanta, Ga

Illinois Committee on Public Utility Information
(Illinois)

Chairman, John F Gilchrist, Commonwealth Edison Co, Chicago, Ill
Director, Bernard J Mulaney, Peoples Gas Light & Coke Co, Chicago, Ill
Assistant Director, R R McGregor, 79 West Monroe Street, Chicago, Ill

Indiana Committee on Public Utility Information
(Indiana)

Chairman, (To be appointed)
Manager, William Stokes, 1547 Consolidated Building, Indianapolis, Ind

Iowa Committee on Public Utility Information
(Iowa)

Chairman, F J Hanlon, Peoples Gas & Electric Co, Mason City, Iowa
Director, Joe Carmichael, 310 Crocker Building, Des Moines, Iowa

Information Bureau of Kansas Public Service Companies
(Kansas)

Chairman, L O Ripley, Kansas Gas & Electric Co, Wichita, Kan
Director, H Lee Jones, 820 Kansas Ave, Topeka, Kan

Kentucky Committee on Public Utility Information
(Kentucky)

Chairman, Robert Montgomery, Louisville Gas & Electric Co, Louisville, Ky
Secretary, E F Kelley, Louisville Railway Co, Louisville, Ky

Louisiana-Mississippi Committee on Public Utility Information
(Louisiana-Mississippi)

Chairman, H B Flowers, New Orleans Public Service Inc, New Orleans, La
Director, Hugh M Blain, 1426 Hibernia Building, New Orleans, La

Michigan Committee on Public Utility Information
(Michigan)

Chairman, A C Marshall, The Detroit Edison Co, Detroit, Mich
Director, Arthur W Stace, 202 East Washington Street, Ann Arbor, Mich

Missouri Committee on Public Utility Information
(*Missouri*)

Chairman, Percy Redmund, Southwestern Bell Telephone Co, St Louis, Mo
Acting Secretary, Jesse Blythe, 1017 Olive Street, St Louis, Mo

Nebraska Utilities Information Bureau
(*Nebraska*)

Chairman, K R MacKinnon, Nebraska Power Co, Omaha, Neb
Director, Thorne Browne, 1527 Sharp Building, Lincoln, Neb

New England Bureau of Public Service Information
(*Maine, New Hampshire, Vermont, Massachusetts and Rhode Island*)

Chairman, W A Buttrick, The Twin State Gas & Electric Co, Boston, Mass
Director, Samuel T MacQuarrie, 24 Milk Street, Boston, Mass

New Jersey Public Utility Information Committee
(*New Jersey*)

Chairman, C H Howell, Atlantic City Electric Co, Atlantic City, N J
Director, A G MacKenzie, 313 Market Street, Camden, N J

New York State Committee on Public Utility Information
(*New York*)

Chairman, E H Rosenquest, Westchester Lighting Co, Mt Vernon, N Y
Director, A Von Schrader, Grand Central Terminal Building, New York, N Y

North Central Public Utility Information Bureau
(*Minnesota, North Dakota and South Dakota*)

Chairman, W S Robertson, Minnesota Power & Light Co, Duluth, Minn
Director, Charles F Stuart, 803-4 Plymouth Building, Minneapolis, Minn

North and South Carolina Public Utility Information Bureau
(*North Carolina and South Carolina*)

Chairman, N A Cocke, Duke Power Co, Charlotte, N C
Director, S E Boney, 506 Lawyers Building, Raleigh, N C

Ohio Committee on Public Utility Information
(*Ohio*)

Chairman, Robert Lindsay, The Cleveland Electric Illuminating Co, Cleveland, Ohio
Director, Fred J Bollmeyer, 1308 Ulmer Building, Cleveland, Ohio

Oklahoma Public Utility Information Bureau
(*Oklahoma*)

President, Earl R Ernsberger, Southwestern Light & Power Co, Oklahoma City, Okla
Manager, Edward F McKay, 1020-23 Petroleum Building, Oklahoma City, Okla

Oregon Public Utility Information Bureau
(*Oregon*)

Chairman, Franklin T Griffith, Portland Electric Power Co, Portland, Ore
Manager, H L Walther, 1015 Public Service Building, Portland, Ore

Pennsylvania Public Service Information Committee
(*Pennsylvania*)

Chairman, P H Gadsden, The United Gas Improvement Co, Philadelphia, Pa

Rocky Mountain Committee on Public Utility Information
(*Colorado, New Mexico and Wyoming*)

Chairman, V L Board, Public Service Co of Colorado, Denver, Colo
Executive Manager, George E Lewis, 406 Gas & Electric Building, Denver, Colo

Tennessee Public Service Information Bureau
(*Tennessee*)

Chairman, J P W Brown, Nashville Railway & Light Co, Nashville, Tenn
Director, Guy P Newbern, 502 Cotton States Building, Nashville, Tenn

Texas Public Service Information Bureau
(*Texas*)

Chairman, Charles W Davis, Dallas Power & Light Co, Dallas, Tex
Director, William C Grant, 412 Santa Fe Building, Dallas, Tex

Virginia Committee on Public Utility Information
(*Virginia*)

President, J W Hancock, Appalachian Electric Power Co, Roanoke, Va
Director, A B Tunis, 301 East Grace Street, Richmond, Va

Information Committee Public Utilities Association of West Virginia
(*West Virginia*)

Chairman, Arthur M Hill, Charleston Interurban Railroad Co, Charleston, W Va
Secretary, A Bliss McCrum, P O Box 1483, Charleston, W Va

Wisconsin Public Utility Information Bureau
(*Wisconsin*)

Chairman, J P Pulliam, Wisconsin Public Service Corp, Milwaukee, Wis
Director, A F Herwig, 432 Broadway, Milwaukee, Wis

Outline of National Electric Light Association Organization as Related to Geographic Divisions

This Outline indicates the opportunities for organization relationship between the Geographic Divisions and the National Electric Light Association, and is intended to assist the Geographic Divisions in the early selection of their representatives to serve on the National Executive Committee, General National Committees and the Bureaus and Committees of the Accounting, Commercial, Engineering and Public Relations National Sections.

The Administrative Year of the National Electric Light Association covers the period of July 1 to June 30. Officers take office and Bureaus and Committees function from July 1 to, and including, June 30, following.

In order that the work of an Administrative Year may be started promptly with the active participation of all concerned, it is desirable that the Geographic Divisions select promptly their representatives, who will serve as members of the National Executive Committee, General National Committees and the Bureaus and Committees of the Accounting, Commercial, Engineering and Public Relations National Section. Thus such representatives will be enabled to participate in the formulation of programs of activities for the Year, which plans are usually determined early in July, and thereby be able, not only to serve as members throughout the Year, but also to be of maximum service to their respective Divisions.

National Executive Committee

The personnel of the National Executive Committee consists of the Officers, the Retiring President, the Members-at-Large, the Chairmen of the four (4) National Sections and the Presiding Officers, or other duly accredited representatives, of the Geographic Divisions—one (1) representative from each Division.

Special National Committees

No provision is made on the Special National Committees for Geographic Division representation. In order that these Special National Committees, on which no provision is made for Geographic Division representation, may not be confused with other Committees of the Association on which provision is made for representation, there follows a list of such Special National Committees:

Advertising Committee
Charles A Coffin Prize Committee
Codes and Standards Committee
Constitution and By-Laws Committee
Electrification of Steam Railroads Committee
Exhibition Committee
Finance Committee
Lamp Committee
Prize Awards Committee
Public Policy Committee
Rate Research Committee
Water Power Development Committee
Wiring Policy Committee

General National Committees

The five (5) General National Committees, operating during the Administrative Year, July 1, 1928—June 30, 1929, on which provision is made for Geographic Division representation, are:

Civic Development Committee
Educational Committee
Insurance Committee
Membership Committee
Rural Electric Service Committee

Included in the personnel of these five (5) Committees are two (2) groups of members, namely, Members-at-Large and Geographic Division representatives.

"Members-at-Large" are appointed either by the President or by the Chairmen of the Committees. Such members are selected because of their special qualifications and are located in different sections of the country. They, however, are not regarded, nor do they act, as Geographic Division Representatives—they are, as their title indicates, members-at-large.

Geographic Division representation on the General National Committees is effected in one of two ways:

(a) Where a Geographic Division has a Committee corresponding to a General National Committee, the Chairman of such Division Committee becomes, automatically, a member of the corresponding National Committee.

(b) If a Division does not have a Committee corresponding to a General National Committee, but desires to be represented thereon, the Division may appoint thereto a representative.

Irrespective of the method, (a) or (b) employed, all Geographic Division Representatives members of General National Committees, are *selected* and *appointed* by the Divisions—not, in any case, by the National Association.

Each Geographic Division is entitled to one (1) representative on each General National Committee.

National Sections' Executive Committees

There are four (4) National Sections, namely, Accounting, Commercial, Engineering and Public Relations, each of which has an Executive Committee. Each Geographic Division may have Accounting, Commercial, Engineering and Public Relations Sections, and the Chairmen of such Division Sections become, automatically, members of the Executive Committees of the corresponding National Sections. Example: The Chairman of an Accounting Section of a Geographic Division becomes, automatically, a member of the Executive Committee of the Accounting National Section.

The Chairmen of the Divisions' Sections are *selected* and *appointed* by the Divisions.

National Sections' Bureaus and Committees

The Accounting, Engineering and Public Relations National Sections have Committees, on a number of which provision is made for Geographic Division representation in addition to the members-at-large. The Commercial National Section has both Bureaus and Committees. A Bureau consists of a number of Committees handling kindred subjects. Provision is made for Geographic Division representatives on the Bureaus, but not on the Committees of the Bureaus. There are also Committees, which are not related to the Bureaus, on two of which Committees provision is made for Geographic Division representatives.

"Members-at-Large" are appointed by either the Chairmen of the National Sections embracing such Bureaus and Committees, or by the Chairmen of such Bureaus and Committees. Such members are selected because of their qualifications and are located in different sections of the country. They, however, are not regarded, nor do they act, as Geographic Division representatives—they are, as their title indicates, members-at-large.

Geographic Division representation on the Bureaus and Committees of the four National Sections is effected in one of two ways:

(a) Where a Section of a Geographic Division has a Bureau or a Committee corresponding to a Bureau or Committee of a National Section, on which provision is made for Geographic Division representation, the Chairman of such Division Section Bureau or Committee becomes, automatically, a member of the corresponding National Section Bureau or Committee.

(b) If a Section of a Geographic Division does not have a Bureau or Committee corresponding to a Bureau or a Committee of a National Section, on which provision is made for Geographic Division representation, but desires to be represented on such Bureau or Committee, the Division may appoint thereto a representative.

Irrespective of the method (a) or (b) used, all Division Representatives, members of Bureaus or Committees of the National Sections, are *selected* and *appointed* by the Geographic Divisions—not, in any case, by the Chairmen of the National Bureaus or Committees.

Each Geographic Division is entitled to one (1) representative on each of the following indicated Bureaus and Committees of the four National Sections.

Follows a list of National Sections' Bureaus and Committees, operating during the Administrative Year, July 1, 1928—June 30, 1929, on which provision is made for Geographic Division Representation:

Accounting National Section
- Section's Executive Committee
- Classification of Accounts Committee
- Customers' Records Committee
- Fixed Capital Committee
- General Records Committee
- Purchasing and Storeroom Committee
- Statistics Committee

Commercial National Section
- Section's Executive Committee
- Commercial and Industrial Power and Heating Bureau
- Lighting Bureau
- Merchandising Bureau
- Customer Relations Committee
- Wiring Sales Committee

Engineering National Section
- Section's Executive Committee
- Accident Prevention Committee
- Electric Apparatus Committee
- Hydraulic Power Committee
- Inductive Coordination Committee
- Meter Committee
- Overhead Systems Committee
- Power Systems Committee
- Prime Movers Committee
- Underground Systems Committee

Public Relations National Section
- Section's Executive Committee
- Cooperation with Educational Institutions Committee
- Customer Ownership Committee
- Industrial Relations Committee
- Information Bureau Organizations Committee
- Public Speaking Committee
- Relations with Financial Institutions Committee
- Women's Committee

There are certain Committees of the National Sections on which no provision is made for Geographic Division representation, the personnels of such Committees being entirely of "memberships-at-large." In order that there may be no confusion between these Committees and those on which provision is made for Geographic Division representation, there follows a list of the Committees which do not have Geographic Division representation:

Accounting National Section
- Budget Committee
- Corporate Finance Committee

Commercial National Section
- Commercial Cooking Committee
- Electric Truck Committee
- General Power Committee
- Industrial Heating Committee
- Commercial and Industrial Lighting Committee
- Electrical Advertising Committee
- Home Lighting Committee
- Street Lighting Committee
- Domestic Electric Range Committee
- Merchandise Sales Committee
- Refrigeration Committee
- Water Heating Committee
- Promotional Rates Committee

Engineering National Section
- Engineering Administration Committee
- Special Engineering Research Committee

Public Relations National Section
- Manufacturers' Advertising Committee

PERSONNEL INFORMATION DESIRED

Experience indicates that most satisfactory results are obtained if all personnel information bearing on Sections, Bureaus and Committees of a Geographic Division is cleared through the office of the Secretary of a Division; for example, when a person has accepted appointment as Chairman of a Section, Bureau or Committee of a Division, the name, company affiliation and address of such person should be transmitted to the Secretary of the Division, and not to the Chairman of the corresponding national unit, except in very special cases, in which event copy of such advice should be sent to the Division Secretary and the National Secretary.

When a formal acceptance of an appointment has been received, the Secretary of a Geographic Division should forward the name, company affiliation and address of such individual, together with information as to the National Section, Bureau or Committee on which he is to serve, directly to A. Jackson Marshall, Secretary of the National Electric Light Association, 420 Lexington Avenue, New York. This information immediately upon receipt will be sent by the National Secretary to the Chairman of the National Section, Bureau or Committee concerned, and a copy of this advice will be sent to the person concerned and to the Secretary of the Division.

If, for any reason, a Geographic Division does not desire to be represented on a National Section, Bureau or Committee, advices to this effect should be sent to the National Secretary as soon after July 1 as possible.

APPENDIX 5

LIST OF MEMBER COMPANIES AS OF JUNE 30, 1929

Light and Power Companies

(Class A)

"Class A members shall be regularly incorporated public service companies engaged in producing and supplying electrical energy for light, heat or power for public use."—*Constitution, Art. III, Sec. 2.*

Alabama

Birmingham	Alabama Power Company
	Birmingham Electric Company
River Falls	River Falls Power Company

Arizona

Flagstaff	Flagstaff Electric Light Company
Phoenix	Arizona Edison Company
	Central Arizona Light & Power Company (300 West Washington Street)
Prescott	The Arizona Power Company (Masonic Temple)
Tucson	The Tucson Gas, Electric Light & Power Company
Winslow	Arizona Electric Power Company (Corner 2nd and Williamson Streets)

Arkansas

Blytheville	Arkansas-Missouri Power Company
Fort Smith	Mississippi Valley Power Company
Helena	Arkansas Utilities Company (615 Cherry Street)
Hot Springs National Park	Citizens Electric Company
Pine Bluff	Arkansas Power & Light Company (411 Main Street)
Warren	Arkansas General Utilities Co. (1 No. Market Square, Harrisburg, Pa.)

California

Bay Point	Bay Point Light & Power Company (125 Main Street)
Fresno	San Joaquin Light & Power Corporation
Los Angeles	Los Angeles Gas & Electric Corporation (Box 1100 Station C)
	Southern California Edison Company
Riverside	The Southern Sierras Power Company (771 West 8th Street)
St. Helena	Napa Valley Electric Company (Main Street)
San Diego	San Diego Consolidated Gas & Electric Company (P. O. Box 1374)
San Francisco	Feather River Power Company (530 Bush Street)
	Great Western Power Company of California, 225 Bush Street)
	Pacific Gas & Electric Company (245 Market Street)
	Peoples California Hydro-Electric Corporation (212 Fitzpatrick Bldg., Portland, Ore.)
Santa Cruz	Coast Counties Gas & Electric Company (2500 Russ Bldg.), San Francisco, Cal.
Vallejo	Vallejo Electric Light & Power Company (Bin "R")

Colorado

Denver	Arvada Electric Company (1066 Gas & Electric Bldg.)
	Public Service Company of Colorado
Durango	Western Colorado Power Company
Evergreen	Evergreen Public Service Company
Glenwood Springs	The Glenwood Light & Water Company
Golden	Colorado Central Power Company
Greeley	The Home Gas & Electric Company
Pueblo	Southern Colorado Power Company
Silverton	The Silverton Electric Light Company
Springfield	Highland Utilities Company
Trinidad	The Trinidad Electric Transmission Railway & Gas Company

Connecticut

Danbury	Danbury & Bethel Gas & Electric Light Company
Derby	The Derby Gas & Electric Company
East Hampton	Central Connecticut Power & Light Company
Hartford	The Hartford Electric Light Company
Litchfield	The Litchfield Electric Light & Power Company
Mystic	Mystic Power Company
New London	Connecticut Power Company (33 Union Street)
Norwich	The Eastern Connecticut Power Company
South Manchester	Manchester Electric Company
Stamford	The Stamford Gas & Electric Company (429 Atlantic Street)
Thompsonville	The Northern Connecticut Power Company
Unionville	The Union Electric Light & Power Company (Perry Street)
Waterbury	The Connecticut Light & Power Company
Willimantic	Rockville-Willimantic Lighting Company (850 Main Street)

Delaware

Wilmington	Delaware Power & Light Company (834 Market Street)

District of Columbia

Washington	Potomac Electric Power Company

Florida

Auburndale	Auburndale Power Company
Fernandina	Southern States Power Company
Hastings	Hastings Power & Ice Company
Key West	The Key West Electric Company
Madison	Madison County Power Company
Miami	Florida Power & Light Company (Box 875)
Monticello	The Jefferson County Power Company
Pensacola	Gulf Power Company (42 South Palatox Street)
Perry	Taylor County Power Company
St. Petersburg	Florida Power Corporation (P. O. Box 2261)
Tampa	Tampa Electric Company

Georgia

Albany	South Georgia Power Company (Columbus)
Atlanta	Georgia Power Company (Electric & Gas Bldg.)
Blue Ridge	Toccoa Electric Power Company (Tenn. Elec. Power Bldg., Chattanooga, Tenn.)
Columbus	Columbus Electric & Power Company
Griffin	Georgia Hydro-Electric Company
Savannah	Savannah Electric & Power Company
Valdosta	Georgia Power & Light Company

Idaho

Boise	Idaho Power Company
Cœur D'Alene	Kootenai Power Company, Limited
Salmon	Salmon River Power & Light Company

Illinois

Alton	Alton Light & Power Company (122 East Broadway)
Aurora	Western United Gas & Electric Company
Chicago	Bayfield Utilities Company (105 West Adams Street) Byllesby Engineering & Management Corporation (231 South LaSalle Street) Central Public Service Corporation (105 West Adams Street) Commonwealth Edison Company (72 West Adams Street) Illinois Power & Light Corporation (231 South LaSalle Street) Inland Power & Light Company (79 West Monroe Street) Middle West Utilities Company (72 West Adams Street) Midland Utilities Company (2025-122 South Michigan Avenue) National Public Utilities Company (39 South La Salle Street, Room 402) North American Light & Power Company (231 South La Salle Street) North Continent Utilities Corp. (2311 South La Salle Street, Room 1833) Public Service Company of Northern Illinois (72 West Adams Street) The United Light & Power Company (2200 Bankers Bldg.) United Public Service Company (100 West Monroe Street) Utilities Management Company (29 South LaSalle Street) Utilities Power & Light Corporation (327 South LaSalle Street)
Dixon	Illinois Northern Utilities Company
East St. Louis	East St. Louis Light & Power Company
Galena	Interstate Light & Power Company (103 Main Street)
Lincoln	Illinois Public Utility Company
Moline	Peoples' Power Company
Mt. Carmel	Mt. Carmel Public Utility & Service Company
Peoria	Central Illinois Light Company
Rockford	Rockford Electric Company
Springfield	Central Illinois Public Service Company Illinois Power Company

Indiana

Attica	Attica Electric Company (117 N. Brady St.)
Clinton	Wabash Valley Electric Company
Evansville	Southern Indiana Gas & Electric Company
Fort Wayne	Indiana Service Corp. (122 E. Wayne St.)
Greensburg	Hoosier Public Utility Company
Hammond	Northern Indiana Public Service Company (649 Hohman St.)
Indianapolis	Central Indiana Power Company (606 Guaranty Bldg.) Indianapolis Power & Light Company (48 Monument Circle) Interstate Public Service Company (Wild Bldg., 129 E. Market)
Kokomo	Northern Indiana Power Company
La Porte	La Porte Gas & Electric Company
Madison	Madison Light & Power Company
Marengo	General Utilities Company
Marion	Indiana General Service Company
Richmond	The Liberty Light & Power Company
South Bend	Indiana & Michigan Electric Company
Terre Haute	Terre Haute, Indianapolis & Eastern Traction Company (Terre Haute Division, 301 Tribune Bldg.)
Union City	Union City Electric Company
Winchester	Citizens Heat, Light & Power Company

Iowa

Cedar Rapids	Iowa Electric Company Iowa Railway & Light Corp.
Centerville	Iowa Southern Utilities
Council Bluffs	Citizens Power & Light Company
Davenport	Peoples' Light Company
Des Moines	Iowa Power & Light Company
Dubuque	Central States Power & Light Corp. (First National Bank Bldg.) Eastern Iowa Electric Company Interstate Power Company
Fort Dodge	Fort Dodge Gas & Electric Company
Fort Madison	Fort Madison Electric Company
Glenwood	Mills County Power Company
Iowa City	Iowa City Light & Power Company
Keokuk	Keokuk Electric Company Mississippi River Power Company
Mason City	Peoples Gas & Electric Company
Northwood	Northwood-Kensett Electric Company
Sioux City	Iowa Public Service Company (Box 766) McGraw Electric Company (120 S. La Salle St., Chicago, Ill.) Sioux City Gas & Electric Company

Kansas

Abilene ....The United Power & Light Corporation of Kansas
Caney ....The Caney Electric Company
Concordia ....The Kansas Power Company
Cottonwood Falls .Inter-County Electric Company
Fort Scott ....Kansas Utilities Company (10 East Wall Street)
Lawrence ....Kansas Electric Power Company
Salina ....The Western Light & Power Corp. (The Public Utilities Investment Company Bldg.)
Topeka ....The Kansas Power & Light Company
Wichita ....Kansas Gas & Electric Company (Sedgwick Bldg., 201 No. Market Street)

Kentucky

Bloomfield ......Kentucky Service Company
Bowling Green....Kentucky-Tennessee Light & Power Company (910 State Street)
Covington ....Union Light, Heat & Power Company
Hazard ....Kentucky & West Virginia Power Company
Lexington ....Lexington Utilities Company
Louisville ....Kentucky Utilities Company (Starks Building)
Louisville Gas & Electric Company
Maysville ....Kentucky Power & Light Company

Louisiana

Alexandria ....Louisiana Ice & Utilities, Inc. (2034 Hill Street)
Algiers ....Louisiana Power & Light Company (142 Delaronde Street)
Baton Rouge ....Baton Rouge Electric Company
New Iberia ......Gulf Public Service Company
New Orleans .....New Orleans Public Service, Inc. (Box 340)
Shreveport ....Southwestern Gas & Electric Company

Maine

Augusta ....Central Maine Power Company
New England Public Service Company
Bangor ....Bangor Hydro-Electric Company
Biddeford ....Clark Power Company
Calais ....St. Croix Gas Light Company
Caribou ....Caribou Water, Light & Power Company
Kezar Falls ......Cornish & Kezar Falls Light & Power Company
Lewiston ....Androscoggin Electric Company (Main Street)
Portland ....Cumberland County Power & Light Company
Presque Isle .....Gould Electric Company
Rumford ....Rumford Falls Light & Water Company
South Berwick ...Berwick & Salmon Falls Electric Company (131 State Street, Boston, Mass.)

Maryland

Annapolis ....Annapolis & Chesapeake Bay Power Company

	National Electric Power Company (57 William Street)
	National Public Service Company (57 William Street)
	The New York Edison Company (4 Irving Place)
	North American Gas & Electric Company (57 William Street)
	Peoples Light & Power Corporation (27 William Street, Suite 914-922)
	United Electric Light & Power Company (4 Irving Place)
	The J. G. White Management Corporation (33 Liberty Street)
Queens	Queens Borough Gas & Electric Company (Far Rockaway, N. Y.)
	New York & Queens Electric Light & Power Company (28-19 Bridge Plaza, North, Long Island City, N. Y.)
Richmond	Staten Island Edison Corporation (Lock Box "C," St. George, Staten Island)
Niagara Falls	Niagara Electric Service Corporation (109 Main Street)
	Niagara Falls Power Company
North Tonawanda	Tonawanda Power Company
Nyack	Rockland Light & Power Company
Oneonta	New York State Electric Corporation.
Ossining	Northern Westchester Lighting Company
Oswego	Peoples Gas & Electric Company of Oswego
Patchogue	Patchogue Electric Light Company
Peekskill	Peekskill Lighting & Railroad Company
Plattsburgh	Eastern New York Electric & Gas Company, Inc.
Potsdam	St. Lawrence County Utilities, Inc.
Poughkeepsie	Central Hudson Gas & Electric Corporation (50 Market Street)
Rochester	Rochester Gas & Electric Corporation
Sherrill	Kenwood Electric Light Company
Syracuse	The Syracuse Lighting Company, Inc.
Ticonderoga	The Ticonderoga Electric Light & Power Company (East Exchange Street)
Utica	Utica Gas & Electric Company (258 Genesee Street)
Watertown	Northern New York Utilities, Inc.
Yonkers	Yonkers Electric Light & Power Company (45 South Broadway)

North Carolina

Chapel Hill	University Consolidated Service Plant (Elec. & Water Division)
Durham	Durham Public Service Company
Greensboro	North Carolina Public Service Company
Raleigh	Carolina Power & Light Company
Wilmington	Tide Water Power Company

North Dakota

Amenia	Amenia Power Company
Arthur	Hunter Power Company (Box 44)
Bismarck	North Dakota Power & Light Company
Devil's Lake	Dakota Public Service Company
Fargo	Union Light, Heat & Power Company
Grand Forks	Red River Power Company
Harvey	Central Light & Power Company
Pembina	Interstate Power Company of North Dakota (Dubuque, Iowa)

Ohio

Akron	Northern Ohio Power & Light Company
Alliance	The Suburban Power Company (Alliance First Nat'l Bank Bldg.)
Ansonia	The Ansonia Lighting Company
Athens	The Southern Ohio Electric Company (29 So. Court Street)
Bowling Green	The Ohio Northern Public Service Company (131 W. Wooster Street)
Canton	The Ohio Power Company
Cincinnati	Columbia Engineering & Management Corporation (314 West Fourth Street)
	The Union Gas & Electric Company
Cleveland	The Buckeye Public Service Company (1803 Terminal Tower Bldg.)
	Cleveland Electric Illuminating Company (Box 392)
	The Cleveland Light & Power Company (8 St. Clair Avenue, N. W.)
	The Lake Erie Power & Light Company (Union Trust Bldg.)
	The Ohio Public Service Company (1800 Keith Bldg.)
	The Western Reserve Power & Light Company (1670 Union Trust Bldg.)

Greenville	Pennsylvania Power Company
Holtwood	Pennsylvania Water & Power Company (Lexington Building, Baltimore, Md.)
Johnstown	Pennsylvania Electric Company (Post Office Drawer "G")
Kennett Square	Chester County Light & Power Company
Kingston	Luzerne County Gas & Electric Corporation
Lancaster	Edison Electric Company
La Plume	Abington Electric Company
Mauch Chunk	Mauch Chunk Heat, Power & Electric Light Company
Meadville	Harley D. Carpenter (Box 406)
Mercersburg	Mercersburg, Lehmasters & Markes Electric Company
Milford	Pike County Light & Power Company (Nyack, N. Y.)
Natrona	Natrona Light & Power Company
Norristown	Philadelphia Suburban-Counties Gas & Electric Co. (208-214 De Kalb Street)
Oil City	Keystone Public Service Company (Drake Theater Bldg., Seneca Street)
Oxford	Southern Pennsylvania Power Company (119 South Third Street)
Palmerton	Palmerton Lighting Company (340 Delaware Avenue)
Philadelphia	E. W. Clark Engineering Corporation (321 Chestnut Street) Day & Zimmermann, Inc. (112 North Broad Street) The Philadelphia Electric Company (1000 Chestnut Street) United Gas Improvement Company (Broad and Arch Streets)
Pittsburgh	The Duquesne Light Company The West Penn Electric Company (14 Wood Street) The West Penn Power Company (West Penn Bldg.)
Reading	Metropolitan Edison Company
Renovo	Renovo Edison Light, Heat & Power Company
Scranton	Scranton Electric Company
Tyrone	Home Electric Light & Steam Heating Company
Waterford	Waterford Electric Light Company (East Third Street)
Waynesboro	South Penn Power Company
Wellsboro	Wellsboro Electric Company
Windber	Windber Electric Corporation.
York	Edison Light & Power Company

Rhode Island

Newport	Newport Electric Corporation (204 Thames Street)
Pawtucket	Blackstone Valley Gas & Electric Company
Providence	Narragansett Electric Company
Westerly	South County Public Service Company

South Carolina

Belton	Belton Light & Power Company
Charleston	South Carolina Power Company (141 Meeting Street)
Conway	Quattlebaum Light & Ice Company

South Dakota

Deadwood	Consolidated Power & Light Company
Huron	Northwestern Public Service Company (National Bank Bldg.)
Mobridge	Northern Power & Light Company
Rapid City	The Dakota Power Company
Watertown	Watertown Public Service Company (11 No. Broadway)

Tennessee

Bristol	Bristol Gas & Electric Company
Chattanooga	Southern Cities Power Company (Provident Bldg.) The Tennessee Electric Power Company
Jackson	West Tennessee Power & Light Company (110 Baltimore Street)
Johnson City	Tennessee Eastern Electric Company
Kingsport	Kingsport Utilities, Inc.
Knoxville	Knoxville Power & Light Company (626 South Gay Street)
Memphis	Memphis Power & Light Company
Nashville	Nashville Railway & Light Company
Shelbyville	South Kentucky Power Company (Citizens Bank)
Springfield	Tennessee Light & Power Company

Texas

Abilene	West Texas Utilities Company (Box 127)
Amarillo	Southwestern Public Service Company (526 Taylor Street)
Beaumont	Gulf States Utilities Company (366 Liberty Street)
Borger	Panhandle Power & Light Company (Drawer "I")
Dalhart	Dalhart Public Service Company
Dallas	Central and South West Utilities Company (1100 Allen Bldg.) Dallas Power & Light Company (Interurban Bldg.) Texas Power & Light Company (728 Interurban Bldg.)

Purcellville	Loudoun Light & Power Company
Richmond	Virginia Electric & Power Company
Winchester	Northern Virginia Power Company

Washington

Aberdeen	Grays Harbor Railway & Light Company
Cheney	Cheney Light & Power Company
Colville	Stevens County Power & Light Company
Port Angeles	Northwestern Power & Light Company
Raymond	Willapa Electric Company
Seattle	Puget Sound Power & Light Company Washington Irrigation & Development Company (905 White Bldg.)
Spokane	The Washington Water Power Company
Tacoma	Washington Gas & Electric Company (101 South Tenth Street)

West Virginia

Charleston	Appalachian Electric Power Company Columbia Gas & Electric Corporation (61 Broadway, New York, N. Y.)
Fairmont	Monongahela West Penn Public Service Company
Iaeger	United Light & Power Company
Martinsburg	Potomac Light & Power Company
Mullens	Union Power Company (c/o W. Va. Engineering Co., Kanawha National Bank Bldg., Charles)
Petersburg	Community Power Company Potomac Valley Power Corporation
Piedmont	Piedmont Electric Light & Power Company
War	War Light & Water Company
Wheeling	Wheeling Electric Company

Wisconsin

Abbotsford	Midland Public Service Company
Amery	Wisconsin Hydro Electric Company
Ashland	Lake Superior District Power Company
Eau Claire	Northern States Power Company of Wisconsin
Green Bay	Wisconsin Public Service Corporation
Lake Geneva	Southern Wisconsin Electric Company (260 Broad Street)
Madison	Madison Gas & Electric Company Wisconsin Power & Light Company (Suite 900, Gay Bldg., 16 Carroll Street)
Milwaukee	Milwaukee Electric Railway & Light Company
Prairie du Chien	Interstate Power Company of Wisconsin (1000 Main Street, Dubuque)
Racine	Wisconsin Gas & Electric Company (305 Sixth Street)
Superior	Superior Water, Light & Power Company
Waupaca	Waupaca Electric Service & Railway Company
Wausau	Wisconsin Valley Electric Company
West Bend	Wisconsin Public Utility Company

Wyoming

Casper	Mountain States Power Company (Wyoming Division)
Cheyenne	The Cheyenne Light, Fuel & Power Company (1704-06 Capitol Avenue)
Lander	Lander Electric Light & Power Company
Rawlins	The Rawlins Electric Light & Fuel Company (Box 527)
Sheridan	The Sheridan County Electric Company

UNITED STATES POSSESSIONS

Alaska

Cordova	Alaska Public Utilities
Juneau	Alaska Electric Light & Power Company
Ketchikan	Citizens Light, Power & Water Company
Valdez	Prince William Sound Water Power, Light & Telephone Company

Hawaii

Hilo	Hilo Electric Light Company, Limited
Honolulu	The Hawaiian Electric Company, Ltd. (900 Richards Street)

Philippine Islands

Manila	The Manila Electric Company

Porto Rico

Ponce	Ponce Electric Company
San Juan	Porto Rico Railway, Light & Power Company

CANADA

Alberta

Calgary	Calgary Power Company, Limited (164 St. James Street, Montreal, Quebec) Canadian Utilities, Limited (215 Sixth Avenue, West)

St. Johns	Newfoundland Light & Power Company, Limited (P. O. Box 823) United Towns Electric Company, Limited

Manufacturer Companies

(Class D)

"Class D members shall be companies or firms engaged in the manufacture of apparatus, machinery, equipment, supplies or material for the production or use of Electrical energy."—*Constitution, Art. III, Sec.* 5.

Alabama

Birmingham .....Bessemer Galvanizing Works (205 Phoenix Bldg.)

California

Alhambra ....C. F. Braun & Company

Los Angeles .....Diamond Electrical Manufacturing Company (1320 East Sixteenth Street)
Kelman Electric & Mfg. Company (1650 Naud Street)

San Francisco ....General Appliance Corp. (44 Whitehall Street, New York, N. Y.)
Majestic Electric Appliance Company, Inc. (590 Folsom Street)
Pacific Coast Steel Company (Hunter-Dulin Bldg.)
Pacific Electric Manufacturing Company (5815 Third Street)
The Pelton Water Wheel Company (19th and Harrison Streets)

Connecticut

Ansonia ....The Ansonia Electrical Company (63 Main Street)

Branford ....Malleable Iron Fittings Company (Pole Hardware Department)

Bridgeport ....Bridgeport Brass Company (475 Fifth Avenue, New York, N. Y.)
Bryant Electric Company
Harvey Hubbell, Inc.

Hartford ....Colt's Patent Fire Arms Mfg. Co. (Electrical Division)
The Hart Manufacturing Company (Hamilton Street)
The States Company (19 New Park Avenue)

Meriden ....Manning, Bowman & Company
The Miller Company (99 Center Street)

New Britain .....Landers, Frary & Clark

New Haven ......The Bigelow Company (P. O. Drawer 706)
The National Electric Condenser Company (P. O. Box 1820)
Products Protection Corporation (P. O. Box 904)
Rockbestos Products Corporation (P. O. Box 1102)
Whirldry Corporation (c/o Winchester Repeating Arms Co.)

Plainville ....The Trumbull Electric Manufacturing Company

Torrington ......The Fitzgerald Mfg. Company (Main Street)

Waterbury ....The American Brass Company (c/o Anaconda Copper Mining Co., 25 Broadway, New York, N. Y.)
The Beardsley & Wolcott Mfg. Company (125 Maple Street)
The Bristol Company
Scovill Manufacturing Company

Delaware

Edge Moor ......Edge Moor Iron Company

Florida

Jacksonville ....American Cross Arms Company, Inc. (P. O. Box 82)

Illinois

Bloomington .....Williams Oil-O-Matic Heating Corp.

Chicago ....American Concrete Marbelite Company (232 East Erie Street)
American Insulated Wire Div. of General Cable Corporation (954 West 21st Street)
American Ironing Machine Company (100 East Ohio Street)
Anaconda Wire and Cable Company Rolling Mills Department (25 Broadway, Room 1870, New York, N. Y.)
Automatic Burner Corp. (312 North May Street)
Beardslee Chandelier Manufacturing Company (216-20 South Jefferson Street)
Benjamin Electric Manufacturing Company (128 South Sangamon Street)
Chicago Flexible Shaft Company (5600 West Roosevelt Road)
The Conover Company (140 South Dearborn Street)
Continental Valve & Equipment Company (82 Herbert Street, Framingham, Mass.)
Crane Company (836 South Michigan Avenue)
Crane Packing Company (1800 Cuyler Avenue)
Curtis Lighting, Inc. (1119 West Jackson Boulevard)
Delta Star Electric Company (2433-2443 Fulton Street)
Economy Fuse & Manufacturing Company (Greenview Avenue at Diversey Parkway)
Edison Electric Appliance Company, Inc. (5660 West Taylor Street)
Federal Electric Company (8700 South State Street)
G. & W. Electric Specialty Company (7780 Dante Avenue, Grand Crossing Station)
Hurley Machine Company (Division of Electric Household Utilities Corporation, West 22d Street and 54th Avenue)
Paul E. Johnson, Inc. (1824 South Albert Street)
Mathias Klein & Sons (3200 Belmont Avenue)
Kulp Theft Proof Lamp Company (330 South Wells Street)
Max Marquiz (4821 Sheridan Road)
The Mercoid Corp. (25 Church Street, Room 307, New York, N. Y.)

Illinois (*Continued*)

Chicago (***Continued***) .... Minerallac Electric Company (25 North Peoria Street)
Naugle Pole & Tie Company (5 South Wabash Avenue)
Reynolds Electric Company (2650 West Congress Street)
Royal Electric Manufacturing Company (619-621 East 40th Street)
W. H. Salisbury & Company, Inc. (308 West Madison Street)
Schweitzer & Conrad, Inc. (4431-4439 Ravenswood Avenue)
Standard Oil Company of Indiana, Tech. Div., Lubg. Dept. (910 South Michigan Avenue)
Taylor Forge & Pipe Works (Box 485)
Triplex Washing Machine Corp. (644 West Lake Street)
Victor X-Ray Corporation (2012 Jackson Boulevard)
Walker Vehicle Company (87th and State Streets, Chesterfield Station)

Harvey .... The Buda Company

Macomb .... Illinois Electric Porcelain Company (512 North Pearl Street)

Peoria .... Altorfer Brothers Company

Rockford .... George D. Roper Corporation

Rock Island ..... Rock Island Manufacturing Company (First Street at Fifteenth Avenue)

Springfield .... Sangamo Electric Company
Springfield Boiler Company (1901 East Capitol Avenue)

Sycamore .... Inland Wire & Cable Company

Indiana

Brazil .... The Clay Products Company

East Chicago ..... Edward Valve & Manufacturing Company (1200 W. 145th Street)

Evansville .... Servel, Inc.

Gary .... Walter Bates Steel Corporation (East Fifth Avenue)

Indianapolis ..... Transelectric Company (518 Traction Terminal Building)

Lafayette .... Duncan Electric Manufacturing Company

Marion .... Rutenber Electric Company

South Bend ...... South Bend Current Controller Company (P. O. Box 245)

Iowa

Council Bluffs .... Giant Manufacturing Company

Newton .... Automatic Washer Company, Inc.
One Minute Manufacturing Company

Kentucky

Covington .... The Wadsworth Electric Manufacturing Company, Inc. (22-30 West Eleventh Street)

Maine

Portland .... Brown Company (Fibre Conduit Dept.)

Maryland

Baltimore .... Locke Insulator Corporation (Maryland Trust Company Bldg.)
May Oil Burner Corp. (3500 East Biddle Street)
Standard Gas Equipment Corp., Acorn Div. (Bayard and Hamburg Streets)

Massachusetts

Ashland .... Warren Telechron Company

Boston .... Albert & J. M. Anderson Manufacturing Company (289-305 A Street, Boston 9,)
Bernitz Furnace Appliance Company (Public Service Bldg., 89 Broad Street)
Condit Electrical Manufacturing Corporation (838 Summer Street)
The Dampney Company of America (50-60 Business Street, Hyde Park)
Holtzer-Cabot Electric Company (125 Amory Street, Roxbury)
Simplex Wire & Cable Company (201 Devonshire Street)
Stets Company (141 Milk Street)
B. F. Sturtevant Company (Hyde Park)
Tower Manufacturing Company (122 Brookline Avenue)
Walker & Pratt Manufacturing Company (31-35 Union Street)
Walworth Company (Statler Bldg.)
Wheeler Reflector Company (275 Congress Street)

Medford Hillside . Doble Engineering Company

Springfield .... American Electric Service & Maintenance Company (P. O. Box 1231)

Waltham .... The Palmer Electric & Mfg. Co. (corner of Pond and Exchange Streets)

Watertown ...... Hood Rubber Company (Nichols Avenue)

Worcester .... American Steel & Wire Company (94 Grove Street)
Devon Manufacturing Company (677 Cambridge Street)
Riley Stoker Corporation (9 Neponset Street)
M. S. Wright Company (164 Fremont Street)

Michigan

Battle Creek ...... H. B. Sherman Manufacturing Company (9 Barney Street)

Bay City .... Kuhlman Electric Company

Detroit .... American Electrical Heater Company
Bartlett Manufacturing Company (743 Beaubien Street)
Burroughs Adding Machine Company (6071 Second Boulevard)
Copeland Products, Inc. (630 Lycaste Avenue)
Diamond Power Specialty Corporation (10340 Oakland Avenue)
Electrovent Corp. (5057 Woodward Avenue)
Eureka Vacuum Cleaner Company (Hamilton and Dewey Avenues)
General Utilities Manufacturing Company (2587 East Grand Boulevard)
Ironrite Ironer Company (38 Piquette Avenue)
Kelvinator Corporation (14250 Plymouth Road)
Knott & Garllus Company (3945-3951 "A" Street)
The Peninsular Stove Company (1417 Fort Street West)
Square D Company (6060 Rivard Street)
Whitehead Refrigeration Company (3730 Woodward Avenue)

Grand Rapids .... Leonard Div. of Kelvinator Corp., Clyde Park Avenue)

Michigan (*Continued*)

Jackson ....Reynolds Spring Company (North East Avenue)
St. Joseph ....Upton Machine Company
Wayne ....Deceleco, Inc.

Minnesota

Minneapolis ......B. J. Carney & Company (100 N. 7th Street)
Electric Machinery Manufacturing Company (1331 N. E. Tyler Street)
National Pole & Treating Company (1100 Builders Exchange Building)
The Valentine-Clark Company (P. O. Box 1797)
Waters-Genter Company (213 N. Second)
St. Paul ....Bohn Refrigerator Company (1350 University Avenue)
Seeger Refrigerator Company (Arcade-Wells-Whitehall Streets)

Missouri

Centralia ....Chance Company (Allen at Wilson)
St. Louis ....Century Electric Company (1827 Pine Street)
Electrol, Incorporated (170 Dorcas Street)
Emerson Electric Manufacturing Company (2018 Washington Avenue)
The Edwin F. Guth Company (2615 Washington Avenue)
Jas. R. Kearney Corporation (4224 Clayton Avenue)
W. N. Matthews Corporation (3722 Forest Park)
Moloney Electric Company (5390 Kingshighway, N. W.)
St. Louis Malleable Casting Company (7701 N. Conduit Avenue)
Wagner Electric Corporation (6400 Plymouth Avenue)

Nebraska

Omaha ....Clark Electric Water Heater, Division of McGraw Electric Company (13th and Capitol Avenue)

New Hampshire

Laconia ....Laconia Car Company

New Jersey

Garwood ....Diamond Expansion Bolt Company
Gloucester City ..Welsbach Company (Essex and Ellis)
Harrison ....Driver-Harris Company
Edison Lamp Works of General Electric Company
Hoboken ....Cooper Hewitt Electric Company (410 Eighth Street)
Newark ....American Transformer Company (178-182 Emmet Street)
Baker & Company, Inc. (54 Austin Street)
Hanovia Chemical & Manufacturing Company (Chestnut Street and N. J. R. R. Avenue)
Weston Electrical Instrument Corporation (614 Frelinghuysen Avenue)
Orange ....Edison Storage Battery Company
Thomas A. Edison, Inc., Edicraft Division (P. O. Box 543)
Passaic ....The Okonite Company (501 Fifth Avenue, New York, N. Y.)
The Okonite-Callender Cable Company, Inc. (501 Fifth Avenue, New York, N. Y.)
Trenton ....Circle F Manufacturing Company (720 Monmouth Street)
De Laval Steam Turbine Company
Imperial Porcelain Works
Panelyte Corp. (Enterprise Avenue)
John A. Roebling's Sons Company (640 South Broad Street)

New York

Albany ....Hynes & Cox Electric Corp. (406 No. Pearl Street)
Beacon ....The Green Fuel Economizer Company
Binghamton ......Nineteen Hundred Corp. (255 Clinton Street)
Buffalo ....The Flexlume Corp. (1100 Military Road)
Remington Rand Business Service, Inc. (465 Washington Street)
Savory, Inc. (90 Alabama Street)
Corning ....Corning Glass Works
Jamestown ....Blackstone Manufacturing Company (56-58 Blackstone Avenue)
Johnson City ....Central Flatiron Manufacturing Company
LeRoy ....Lapp Insulator Company, Inc.
Lima ....The Porcelain Insulator Corp.
Mount Vernon ...Ward Motor Vehicle Company (South Fulton Avenue)

New York City:

Brooklyn ......Gleason-Tiebout Glass Company (99 Commercial Street)
Lackner Products Corp. (135 Luqueer Street)
Metropolitan Device Corporation (1250 Atlantic Avenue)
Albert Wahle Company, Inc. (Metropolitan and Morgan Avenues)
Manhattan .....Alberene Stone Company (153 West 23rd Street)
American Brown Boveri Electric Corporation (Graybar Building, 420 Lexington Avenue)
American Flexible Shaft Manufacturing Corp. (331 Madison Avenue)
The Babcock & Wilcox Company (85 Liberty Street)
Bakelite Corporation (247 Park Avenue)
Bishop Wire & Cable Corporation (420 East 25th Street)
Borne Scrymser Company (Whitehall Building, 17 Battery Place)
Bullard-Davis, Inc. (67 Wall Street)
Burndy Engineering Company, Inc. (10 East 43rd Street)
Claude Neon Lights, Inc. (41 East 42nd Street)
Coal Conversion Corp. (285 Madison Avenue, Room 1214)
Combustion Engineering Corporation (200 Madison Avenue)
Consolidated Ashcroft Hancock Company, Inc. (100 East 42nd Street)
Curtin-Howe Corporation (11 Park Place)
The De Laval Separator Company (165 Broadway)

New York (*Continued*)

New York City:

Manhattan (*Continued*) ..... Dexter Rubber Corp. (2 West 45th Street)
Dossert & Company (242 West 41st Street)
Dubilier Condenser Corp. (342 Madison Avenue)
Electrical Research Products, Inc. (250 West 57th Street)
The Engineer Company (17 Battery Place)
The Engineering Products Corporation, Inc. (25 Church Street, Room 309)
Foster Wheeler Corporation (165 Broadway)
General Office Equipment Corp. (342 Madison Avenue)
General Outdoor Advertising Company, Inc. (1 Park Avenue)
Gould Storage Battery Company, Inc. (250 Park Avenue)
The Griscom-Russell Company (285 Madison Avenue)
Habirshaw Cable & Wire Corp. (233 Broadway—Room 2636)
Holophane Company, Inc. (342 Madison Avenue)
Ingersoll-Rand Company (A. S. Cameron Steam Pump Works, 11 Broadway)
International Business Machines Corp. (50 Broad Street)
The International Nickel Company (67 Wall Street)
Johns-Manville, Corp. (Madison Avenue and 41st Street)
Kellems Products, Inc. (6 Varick Street)
The Kempton Manufacturing Corp. (148 West 23rd Street.
Kerite Insulated Wire & Cable Company (Hudson Terminal Building, 30 Church Street)
Walter Kidde & Co., Inc. (140 Cedar Street)
Lightolier Company (569 Broadway)
Luckenbach & Hallberg, Inc. (29 West 57th Street)
Mica Insulator Company (200 Varick Street)
National Electric Products Corp. (233 Broadway)
Noma Electric Corporation (340 Hudson Street)
Otis Elevator Company (Otis Building, 260 Eleventh Avenue)
Peerless Insulated Wire & Cable Company (30 Church Street)
The Permutit Company (440 Fourth Avenue)
Portable Light Company, Inc. (12 Warren Street)
Radio Corporation of America (233 Broadway)
The Rawlplug Company, Inc. (66 West Broadway)
Research Corporation (25 West 43rd Street)
Safety Cable Company (420 Lexington Avenue)
Serelco, Inc. (420 Lexington Avenue)
Silvray Company, Inc. (53 West 14th Street)
Smoot Engineering Corporation (136 Liberty Street)
Standard Oil Company of New Jersey (26 Broadway)

New York City:

Manhattan (*Continued*) ..... The Superheater Company (17 East 42nd Street)
The R. Thomas & Sons Company (30 Church Street)
Seth Thomas Clock Company (19 West 44th Street)
Tork Clocks, Inc. (12 East 41st Street)
Vacuum Oil Company (61 Broadway)
Waterbury Cable Service, Inc. (342 Madison Avenue)
Western Electric Company, Inc. (195 Broadway)
Westinghouse Commercial Investment Company (150 Broadway)
Westinghouse Electric International Company (150 Broadway)
Westinghouse Lamp Company (150 Broadway)
Worthington Pump & Machinery Corp. (2 Park Avenue)

Queens .... The Frink Corp. (23-10 Bridge Plaza, South, Long Island City)
Memco Engineering & Manufacturing Company, Inc. (381 Hamilton Street, Long Island City)
Morganite Brush Company, Inc. (3302-3320 Anable Avenue, Long Island City)

Niagara Falls ... Globar Corporation (P. O. Box 618)

Orchard Park.... Park Metalware Company, Inc. (Thorne Avenue and Bank Street)

Port Jervis .... Gillinder Brothers (Erie & Liberty Streets)

Poughkeepsie .... Hoe Corporation (Cottage Street)

Rochester .... North East Electric Company (379 Lyell Avenue)
Rainbow Appliance Corporation (11-27 Hand Street)
Robeson-Rochester Corporation (176 Anderson Avenue)
Vacuumizer Manufacturing Corp. (77 St. Paul Street)

Rome .... Rome Wire Company

Schenectady ...... General Electric Company (Equitable Building, 120 Broadway, New York, N. Y.)
International General Electric Company, Inc. (Att: Commercial Engineer)
York Insulated Wire Dorks of General Electric Company (1737 Broadway, New York, N. Y.)

Solvay .... Pass & Seymour, Inc.

Syracuse .... Archbold-Brady Company (Greenway Avenue)
Syracuse Washing Machine Corp.

Utica .... American LaFrance and Foamite Ind., Inc. (Turner Street)
Savage Arms Corporation (100 East 42nd Street, New York, N. Y.)

Wellsville .... The Air Preheater Corp.

Ohio

Alliance .... The Buckeye Twist Drill Company (496-544 West Ely Street)

Canton .... Nelson & Kuemmerling (718 Brant Building, Cleveland Avenue, N. W.)
Superior Iceless Refrigerator, Inc.
The Superior Switchboard & Devices Company (420 Schroyer Avenue)
The Union Metal Manufacturing Company (Maple Avenue)
The Wilson Rubber Company (1200 Garfield Avenue)

Ohio (*Continued*)

Cincinnati .... Logan County Coal Corp. (2111 Union Central Bldg.)
The Lunkenheimer Company

Cleveland .... The Apex Electrical Manufacturing Company
Bailey Meter Company (1050 Ivanhoe Road)
The Cinderella Washing Machine Company (4300 Euclid Avenue)
Electric Vacuum Cleaner Company, Inc. (Euclid Avenue and Ivanhoe Road)
The P. A. Geier Company (540 East 105th Street)
Hi-Voltage Equipment Company (3305 Croton Avenue)
The Kayline Company (600 Huron Rd.)
National Carbon Company, Inc. (W. 117th Street and Madison Avenue)
National Lamp Works of General Electric Company (Nela Park)

Union Electric Supply Company (60 Pine Street)

South Carolina

Greenville .... J. E. Sirrine & Company

Tennessee

Chattanooga ..... General Electric Supply Corp. (429 Broad Street)

Memphis .... General Electric Supply Corp. (16 South Lauderdale)

Texas

Dallas .... Electric Appliance Company, Inc. (409 Browder Street)
Southwest General Electric Supply Company (1801 North Lamar Street)

Fort Worth ...... Southwestern Laboratories (Box 1008)

Houston .... Southwest General Electric Supply Company (5 North Milam Street)

San Antonio ..... M. L. Diver, Consulting Engineer (P. O. Box 1073)

Utah

Salt Lake City .. Capital Electric Company (P. O. Box 1877)

Virginia

Clifton Forge .... A. H. Grimsley (425 Alleghany Street)

Colemans Falls... Spottswood C. Foster

Norfolk .... Woodhouse Electric Company, Inc. (238 Court Street)

Richmond .... General Electric Supply Corp. (4th and Canal Streets)
Marsden C. Smith, Engineer, Department of Public Utilities (Room 317, City Hall)

Washington

Seattle .... Eicher & Bratt (Colman Building)
Fobes Supply Company (560 First Avenue, South)
Pacific States Electric Company (570 First Avenue, South)
Washington Surveying and Rating Bureau (1100 Alaska Building, P. O. Box 1818)

Spokane .... Fobes Supply Company (152 South Monroe Street)

Wisconsin

Madison .... Fred R. Cutcheon, Engineer (c/o Service Bldg., University of Wisconsin)

Milwaukee .... The American Appraisal Company, 165 East Michigan Street
Julius Andrae & Sons Company (Broadway & Michigan Streets)
The Electric Meter Engineering Company (3712 Vliet Street)
Ed Schuster & Company, Inc. (Third and Garfield (Servel Department)

CANADA

Alberta

Calgary .... Robert MacKay, Esq. (718 Boulevard, N. W.)

British Columbia

Powell River..... Powell River Company, Limited

Manitoba

Winnipeg .... James Veitch, Esq. (C-27, Riverview Mansions)

Nova Scotia

Liverpool .... Mersey Paper Company, Limited

Sydney .... Dominion Iron & Steel Company, Limited (National Trust Company Receiver and Manager)

Ontario

Hamilton .... Allen Engineering Company, Limited (P. O. Box 311)
The Jas. Moncur Electric Co., Limited
Sawyer-Massey, Limited

Kapuskasing ..... Spruce Falls Power & Paper Company

Niagara Falls ..... R. L. Hearn (875 Robert Street)

Ottawa .... Canadian Engineering Standards Association (Bryson Building, 178 Queen Street)
Canadian Hoosier Engineering Company, Limited (Birks Bldg.)
Electrical Standards Laboratory (Department Trade and Commerce, West Block)
General Supply Company of Canada, Limited (356-60 Sparks Street)
John B. McRae, Esq., Consulting Engineer (323 Jackson Building)

Sault Ste. Marie... Abitibi Power & Paper Company, Limited
Geo. H. Kohl, Esq. (Royal Bank Bldg.)

Ontario (*Continued*)

Toronto .... Harry H. Angus, Esq. (Bloor and Balmuto Streets)
F. Jno. Bell (Royal Bank Bldg.)
Canadian & General Finance Company, Limited (357 Bay Street)
Kerry & Chace, Limited (Confederation Life Building)
Wills Maclachlan, Esq. (Room 41B, 2 Bloor Street, East)
Hugh C. MacLean Publications, Limited (347 Adelaide Street, West)
Powerlite Devices, Limited (171 John Street)
University of Toronto

Walkerville ...... The Canadian Bridge Company, Limited

Quebec

Beaupre .... Ste. Anne Paper Company, Limited

Cap de la Madeleine .... Canadian Power & Paper Corp., St. Maurice Division

Grand Mere ..... Canada Power & Paper Corp., Laurentide Division

Kenogami .... Price Bros. & Company, Limited

Montreal .... Babcock, Wilcox & Goldie McCulloch, Limited (P. O. Box 6, St. Henry)
De Gaspe Beaubien & Company (2 Place D'Armes)
Bell Telephone Company of Canada (P. O. Box 150)
Busfield, McLeod, Limited (1440 St. Catherine Street West)
Callard & Company, Limited (890 St. Antoine Street)
Century Electric Company (691 St. Paul Street, West)
Department of Electrical Engineering, McGill University
Ecole Polytechnique (1430 St. Denis Street)
The Engineering Institute of Canada (2050 Mansfield Street)
G. M. Gest, Limited (Power Bldg.)
Griswold & Company, Limited (1111 Beaver Hall Hill)
Inventions, Limited (1070 Bleury Street)
R. S. Kelsch, Esq. (Apt. 43, 1227 Sherbrooke Street, West)
Lake St. John Power & Paper Company, Limited (522 Drummond Building)
R. S. & W. S. Lea, Consulting Engineers (1226 University Street)

Montreal .... Lyman Tube & Supply Company, Limited (10 St. Sophie Lane)
(*Continued*)
George K. McDougall (85 Osborne Street)
A. J. F. Montabone (Room 2-1430 Bleury Street)
Montreal Engineering Company, Limited (164 St. James Street)
Nesbitt, Thomson & Company, Limited (215 St. James Street, West)
G. D. Peters & Company, Ltd. (10 Cathcart Street)
Everard W. Playford (1131 University Street)
Port Alfred Pulp & Paper Corp. (224 Canada Cement Building)
A. E. Sargent, Chief Electrical Engineer, National Breweries, Limited (36 Chaboillez Square)
Arthur Surveyer, Consulting Engineer (1117 St. Catherine Street, West)
George E. Templeman, Esq. (Electrical Comm. of the City of Montreal, 717 Terminal Bldg., 159 Craig Street, West)
Fred Thomson Company, Limited (915 St. Genevieve Street)
Alexander Wilson, Esq. Room 715, New Birks Building)

Quebec .... Anglo-Canadian Pulp and Paper Mills, Limited
Alexander Lariviere, Chief Engineer (Quebec Public Service Comm., Court House)
Mechanics Supply Company, Limited (80-90 St. Paul Street)

Shawinigan Falls . Canada Power & Paper Corp., Belgo Division
Shawinigan Chemicals, Limited

Three Rivers .... Canadian International Paper Company (P. O. Box 510)
The Wabasso Cotton Company, Limited
Wayagamack Pulp & Paper Company, Limited

Westmount .... J. A. Shaw, Esq. (448 Lansdowne Avenue)

Porto Rico

San Juan .... Antillas Electric Corp. (P. O. Box 1009)

Brazil

Rio de Janeiro .. Burton E. Anderson, Electrical Engineer (Emprezas Electricas Brasilerias, S. A., Caixa Postal 883, c/o Mr. P. B. McKee)

FOREIGN MEMBERS

(Class H)

"Class H members shall be individuals or corporations, not residents of the United States or of Canada, engaged in the central station industry, or interested in advancing the use of electrical energy, who shall ally themselves with this association."—*Constitution, Art III, Sec.* 9.

ASIA

China

Canton ....Kwang Tung Electric Supply Company, Limited

Macao ....Macao Electric Lighting Company, Limited (Rua Central, F. J. Gellion, manager)

Federated Malay States

Taiping, Perak....Ernest F. Stephenson (Electrical Inspector's Office)

India

Bombay ....The Tata Hydro-Electric Power Supply Company, Limited (Bombay House, Bruce Street, Fort)

Calcutta ....Calcutta Tramways Company, Limited (7 Church Lane)

Japan

Dairen ....S. Haraguchi, The South Manchuria Electric Company, Limited (Manchuria)

Oiso Yoshiwo, Power Engineer (58 Kushunokicho, South Manchuria)

Kobe ....Mitsubishi Electrical Engineering Company, Limited (Wadasaki-Cho)

Kyoto City....... Kyoto Electric Light Company

Osaka ....Nippon Electric Power Company, Limited (Osaka Bldg., Soze-Cho, Kitaku)

Sanyo Chuo Hydro Electric Company (No. 48 4-chome Kitahama Higashi-Ku)

Ujigawa Electric Company, Limited (Sonezaki Kita-Ku)

Tokyo ....Daido Denryoku Kabushiki Kaisha, (Tokyo Kaijo Building, Marunouchi)

The Electric Association of Japan (1 chome 5 Yuraku-cho Marunouchi)

Electrical Exploitation, Bureau D of Communication (Teishinsho Denkikyoku Gyomuka)

The English Electric Company, Limited (Yuraku Building, Marunouchi)

S. Hirota (22 Denyen-Chofu-Ebara-Gori, near Tokyo)

Keiji Ito (Marunouchi Bldg., Room 682)

Tokiwo Kobayakawa (c-o. Kyosan & Company, 4th Floor, Japan Industrial Bank Building, Marunouchi)

Ryotaro Mitsuda, Doctor of Engineering (Electro-Technical Laboratory)

Hide Mori (Bureau of Electric Power, Ministry of Communications)

Shibaura Engineering Works (Shibaura)

Kozo Tada (Shinyetsu Electric Power Company (c/o Osaka Bldg., Marunouchi)

Tokyo ....Toho Denryoku Kabushiki Kaisha (Kaijo Bldg.)
(*Continued*)

Tokyo Electric Light Company (Sakurada-Hongo-cho, Shibaku)

Yokohama ....The Furukawa Electric Company, Limited (Nishi-Hiranuma)

Java

Bandoeng ....Dienst voor Waterkracht en Electriciteit

Siam

Bangkok ....Siam Electric Corporation, Limited

AUSTRALIA

New South Wales

Sydney ....Australian Commonwealth Engineering Standards Association (Macleay House, 16 College Street)

George Alfred Julius (Culwalla Chambers, Casltereagh Street)

Queensland

Brisbane ....City Electric Light Company, Limited (P. O. Box 403 F. G. P. O.)

John Stephens Just (Box 1067N, G. P. O.)

South Australia

Adelaide ....The Adelaide Electric Supply Company F. W. Wheadon, Engr. and Mgr. (Grenfell Street E.)

Mechanical Supplies, Limited (69 Grenfell Street)

Port Pirie ....The Broken Hill Associated Smelters Property, Limited

Victoria

Melbourne ....Australian General Electric Company (P. O. Box 538)

The Edison Swan Electric Co., Limited (368 Little Collins Street)

Melbourne Electric Supply Company, Limited (19 Queen Street, F. W. Clements, Manager)

NEW ZEALAND

Ashburton ....Herbert George Kemp (P. O. Box 40)

Christchurch .....J. R. Templin (Box 420) C. E. Engineer

Dunedin ....Messrs. Turnbull & Jones, Limited, Electrical Engineers (78-80 Stuart Street, P. O. Box 362, Otago)

Lower Hutt ......Ernest Bickerstaff (P. O. Box 13)

Wellington ......The National Electrical and Engineering Company, Limited (P. O. Box 1055)

TASMANIA

Hobart ....Electrolytic Zinc Company of Australasia, Limited (Box AA-B)

CENTRAL AMERICA

Costa Rica

San Jose ....Compania Nacional de Electricidad (Apartado No. 499)

Guatemala

Guatemala City ..Empresa Guatemalteca de Electricidad 6a, Avenida Eur y 8a, Calle Poniente

Salvador

San Salvador ....Cia de Alumbrado Elec de San Salvador (Apartado No. 186)

EUROPE

Czecho-Slovakia

Prerov ....Stredomoravska Elektrarny Akciova Spolecnost

England

Birmingham .....Belliss and Morcom, Limited (Ledsam Street Works)
Robert Orsettich, General Electric Company, Limited, Witton Works

County Durham ..Synthetic Ammonia & Nitrates, Limited (Billingham Nr Stockton-on-Tees)

Kent ....W. T. Henley Telegraph Works Company, Limited, Research Department, Gravesend

Lancashire ....British Insulated Cables, Limited (Prescot)

Leeds ....William Bradley Woodhouse (36 Park Place)

London ....British Electrical & Allied Manufacturers Association (36 and 38 Kingsway, W. C.)
British Electrical Development Association, Inc. (15 Savoy Street, Strand, W. C. 2)

Santiago .... Compania Chilena de Electricidad, Limitada (Casilla 1557)
Compania General de Electricidad Industrial (Casilla Correo No. 1824)

Colombia

Barranquilla ..... Compania Colombiana de Electricidad (Apartado 58)

Ecuador

Guayaquil .... H. S. Foley, General Manager, Empresa Electrica del Ecuador, Inc.
Quito .... The Quito Electric Light & Power Company (Apartado No. 82)

Uruguay

Montevideo ...... S. Masson. Ing. Jefe de las Usinas Electricas Del Estado

Venezuela

Maracaibo .... Venezuela Power Company, Limited (Avenida Industria)

WEST INDIES

Jamaica

Kingston .... Jamaica Public Service Company, Limited

Cuba

Havana .... Cia Cubana De Electricidad (Monte No. 1)

BERMUDA

Hamilton .... The Bermuda Electric Light, Power & Traction Company (Serpentine Road)

CANAL ZONE

Ancon .... Compania Panamena de Fuerza Y Luz (P. O. Box 2023)

MEXICO

Mexico City ..... Carlos Macias (3a Calle Zarco 59)
Rodolfo C. Rodriquez, Chief Electrical Engineer, National Railways of Mexico (Colonia Station)

APPENDIX 6

PRESIDENTS OF THE ASSOCIATION

*James F. Morrison of Baltimore
*Samuel A. Duncan of Pittsburgh
Edwin R. Weeks of Kansas City
Marsden J. Perry of Providence
*Charles R. Huntley of Buffalo
*James I. Ayer of St. Louis
Edward A. Armstrong of Camden
*M. Judson Francisco of Rutland
*C. H. Wilmerding of Chicago
*Frederic Nicholls of Toronto
Samuel Insull of Chicago
*Alden M. Young of Waterbury
Samuel T. Carnes of Memphis
*James Blake Cahoon of New York
Henry L. Doherty of Denver
Louis A. Ferguson of Chicago
Charles L. Edgar of Boston
Ernest H. Davis of Williamsport
William H. Blood, Jr., of Boston
Arthur Williams of New York
*Dudley Farrand of Newark
*William C. L. Eglin of Philadelphia
*Frank W. Frueauff of Denver
W. W. Freeman of Brooklyn
John F. Gilchrist of Chicago
Frank M. Tait of Dayton
*Joseph B. McCall of Philadelphia
Holton H. Scott of New York
Edward W. Lloyd of Chicago
Herbert A. Wagner of Baltimore
John W. Lieb of New York
Walter F. Wells of Brooklyn
R. H. Ballard of Los Angeles
Martin J. Insull of Chicago
*Milan R. Bump of New York
Frank W. Smith of New York
Walter H. Johnson of Philadelphia
Franklin T. Griffith of Portland
James E. Davidson of Omaha
R. F. Pack of Minneapolis
H. T. Sands of New York
P. S. Arkwright of Atlanta

HONORARY MEMBERS

E. R. Crompton	London, England
Marcel Deprez	Paris, France
George D. Forbes	London, England
*Prof. I. Fujioka	Tokyo, Japan
*Z. T. Gramme	Paris, France
*Dr. John Hopkinson	London, England
*Edouard Hospitalier	Paris, France
Dr. E. L. Nichols	Cornell University, Ithaca, New York
*Baron Alphonse de Rothschild	Paris, France
John T. Sprague	Birmingham, England
*Joseph W. Swan	Lauriston, Bromley, Kent, England
*Prof. Silvanus P. Thompson	Technical College, Finsbury, London, England
*Professor Yashima	Tokyo, Japan
*Lord Kelvin	Glasgow, Scotland
*Prof. Henry A. Rowland	Johns Hopkins University, Baltimore, Maryland
*Charles F. Brush	Cleveland, Ohio
Thomas A. Edison	Orange, New Jersey
Prof. Elihu Thomson	Lynn, Massachusetts
Frank J. Sprague	New York City
*George S. Bowen	Elgin, Illinois
Dr. Edward Weston	Newark, New Jersey
*Sir William Dawson	Montreal, Canada
Frank R. Redpath	Montreal, Canada
Dr. Henry T. Bovey	London, England
Thomas D. Lockwood	Boston, Massachusetts
Nikola Tesla	New York City
*James I. Ayer	Boston, Massachusetts
*Cyrus Osborne Baker	New York City
*Frederic Nicholls	Toronto, Canada
*T. Commerford Martin	New York City
*Dr. Charles Proteus Steinmetz	Schenectady, New York
*George Westinghouse	Pittsburgh, Pennsylvania
Dr. Arthur E. Kennelly	Harvard University, Cambridge, Massachusetts
*Charles A. Coffin	New York City
*A. C. Dunham	Hartford, Connecticut

---

*Deceased.

APPENDIX 7

CONVENTIONS OF THE ASSOCIATION

No.	Place and Date	President
1st	Chicago, Feb. 25-26, 1885	James F. Morrison
2nd	New York, Aug. 18-20, 1885	James F. Morrison
3rd	Baltimore, Feb. 10-12, 1886	James F. Morrison
4th	Detroit, Aug. 31-Sept. 2, 1886	James F. Morrison
5th	Philadelphia, Feb. 15-17, 1887	James F. Morrison
6th	Boston, Aug. 9-11, 1887	James F. Morrison
7th	Pittsburgh, Feb. 2-23, 1888	James F. Morrison
8th	New York, Aug. 29-31, 1888	Samuel A. Duncan
9th	Chicago, Feb. 19-21, 1889	Samuel A. Duncan
10th	Niagara Falls, Aug. 6-8, 1889	Edwin R. Weeks
11th	Kansas City, Feb. 11-14, 1890	Edwin R. Weeks
12th	Cape May, Aug. 19-21, 1890	Marsden J. Perry
13th	Providence, Feb. 17-19, 1891	Marsden J. Perry
14th	Montreal, Sept. 7-10, 1891	Charles R. Huntley
15th	Buffalo, Feb. 23-25, 1892	Charles R. Huntley
16th	St. Louis, Feb. 28-March 2, 1893	James I. Ayer
17th	Washington, Feb. 27-March 2, 1894	Edward A. Armstrong
18th	Cleveland, Feb. 19-21, 1895	M. Judson Francisco
19th	New York, May 5-9, 1896	C. H. Wilmerding
20th	Niagara Falls, June 8-10, 1897	Frederic Nicholls
21st	Chicago, June 7-9, 1898	Samuel Insull
22nd	New York, May 23-25, 1899	Alden M. Young
23rd	Chicago, May 22-24, 1900	Samuel T. Carnes
24th	Niagara Falls, May 21-23, 1901	James Blake Cahoon
25th	Cincinnati, May 20-22, 1902	Henry L. Doherty
26th	Chicago, May 26-28, 1903	Louis A. Ferguson
27th	Boston, May 24-26, 1904	Charles L. Edgar
28th	Denver-Colorado Springs, June 6-11, 1905	Ernest H. Davis
29th	Atlantic City, June 5-8, 1906	William H. Blood, Jr.
30th	Washington, June 4-8, 1907	Arthur Williams
31st	Chicago, May 19-22, 1908	Dudley Farrand
32nd	Atlantic City, June 1-4, 1909	William C. L. Eglin
33rd	St. Louis, May 23-27, 1910	Frank W. Frueauff
34th	New York, May 29-June 2, 1911	W. W. Freeman
35th	Seattle, June 10-14, 1912	John F. Gilchrist
36th	Chicago, June 2-6, 1913	Frank M. Tait
37th	Philadelphia, June 1-5, 1914	Joseph B. McCall
38th	San Francisco, June 7-11, 1915	Holton H. Scott
39th	Chicago, May 22-26, 1916	Edward W. Lloyd
40th	New York City, May 9-10, 1917	Herbert A. Wagner
41st	Atlantic City, June 13-14, 1918	John W. Lieb
42nd	Atlantic City, May 19-22, 1919	Walter F. Wells
43rd	Pasadena, May 18-22, 1920	R. H. Ballard
44th	Chicago, May 31-June 3, 1921	Martin J. Insull
45th	Atlantic City, May 15-19, 1922	Milan R. Bump
46th	New York, June 4-8, 1923	Frank W. Smith
47th	Atlantic City, May 19-23, 1924	Walter H. Johnson
48th	San Francisco, June 15-19, 1925	Franklin T. Griffith
49th	Atlantic City, May 17-21, 1926	James E. Davidson
50th	Atlantic City, June 6-10, 1927	R. F. Pack
51st	Atlantic City, June 4-8, 1928	H. T. Sands
52nd	Atlantic City, June 3-7, 1929	P. S. Arkwright

APPENDIX 8

NUMBERING OF PROCEEDINGS

To facilitate the filing of sets of the Proceedings of the Association, numbers have been assigned to all volumes issued since the inception of the Association in 1885. This will also greatly facilitate reference and citation to the various volumes. Future indexes will refer to the volumes by these numbers

In addition to the PROCEEDINGS there are the following:
Index to PROCEEDINGS, Conventions 1-32, 1885-1909, 243 pages.
Index to PROCEEDINGS, Conventions 32-36, 1909-1913, 272 pages.

New Number	Convention	Year	New Number	Convention	Year
Vol. 1	1st, 2nd and 3rd	1885-86	Vol. 44	35th—Vol. 3	1912
2	4th and 5th	1886-87	45	35th—Vol. 4	1912
3	6th and 7th	1887-88	46	36th—General	1913
4	8th	1888	47	36th—Accounting	1913
5	9th	1889	48	36th—Commercial	1913
6	10th	1889	49	36th—Technical	1913
7	11th	1890	50	37th—General	1914
8	12th	1890	51	37th—Accounting	1914
9	13th	1891	52	37th—Commercial	1914
10	14th	1891	53	37th—Technical	1914
11	15th	1892	54	38th—General	1915
12	16th	1893	55	38th—Accounting	1915
13	17th	1894	56	38th—Commercial	1915
14	18th	1895	57	38th—Technical	1915
15	19th	1896	58	39th—General	1916
16	20th	1897	59	39th—Accounting	1916
17	21st	1898	60	39th—Commercial	1916
18	22nd	1899	61	39th—Electric Vehicle	1916
19	23rd	1900	62	39th—Technical	1916
20	24th	1901	63	40th—General	1917
21	25th	1902	64	40th—Accounting	1917
22	26th	1903	65	40th—Commercial	1917
23	27th—Vol. 1	1904	66	40th—Electric Vehicle	1917
24	27th—Vol. 2	1904	67	40th—Technical	1917
25	28th—Vol. 1	1905	68	41st	1918
26	28th—Vol. 2	1905	69	42nd—General	1919
27	29th—Vol. 1	1906	70	42nd—Accounting	1919
28	29th—Vol. 2	1906	71	42nd—Commercial	1919

  high-pressure cross crackling stills, 1270
  manufacturers' statements, 1300
  miscellaneous statements, 1265
  soot blowers, 1309
  statements by operating companies, 1271
  steam boiler, stability of, 1270
  steam generating capacity of the water tube boiler, 1268
  steam generating unit design and operation, trend, 1259
  steam purifiers, 1325
  superheaters, 1304
  survey of operating steam temperatures, 1265
  thermal stresses, 1269
  valves, 1325
  water columns and water gages, 1321

Building the Load on the Farm, 255
  farmers using 3000 kw-hr. or more per year, 257
  farms served by electric light and power companies, 273
  Red Wing figures, 257

Byllesby Prizes, 54

C

Cable research, 1501

Changeovers, methods of effecting, 934

Chemistry, power station, 1005

Coal and Ash Handling
  bibliography, 1084
  manufacturers' statements, 1079
  member company statements, 1064

Coal, distillation products of, 1177

Code system (see Automatic Train Control Installations)

Code system of continuous inductive control, 741

Coffin, Charles A., Prize Committee Report, by P. S. Arkwright, 177

Colleges, relations with, 168

Combustion, study of chemistry of, 1005

Commercial
  marketing problem, 5

"Commercial Development," by C. E. Groesbeck, 129

Commercial National Section, 115
  address by C. E. Groesbeck, 129
  address by Martin J. Insull, 128
  address by Gerard Swope, 127
  committee reports, 307
  nominations, 135
  report on, 41

Committees (see specific titles of committees)

Condensers, synchronous, use of hydro-electric units as, 640

Condensing Equipment
  experience with condensers having tubes rolled into tube sheets at both ends, 1491
  operating company statements, 1465
  study of performance record of single-pass and two-pass condensers, 1458
    air leakage, 1464
    circulating water leakage, 1464
    circulating water quantities, 1463
    cleaning of condenser tubes, 1464
    comparison of heat transfer, 1458
    depression of the condensate temperature, 1464
    effect of circulating water temperature on heat transfer, 1464
    effect of circulating water velocity on heat transfer, 1463
    power consumption of circulating pumps, 1464
    relation of the actual to the expected coefficient of heat transfer, 1458
    vertical condensers, 1462
  tube vibration and condenser leakage, 1490

Constitution of the N. E. L. A., 1656

Constitution and By-Laws Committee, Report, 25

Constitution of the N. E. L. A.
  amendments, 1662
  Association magazine, 1662
  committees, 1659

  parliamentary rules, 1662
  permanent office, 1662
  quorum, 1662
  state associations, 1661
  voting and proxies, 1662

Constitutional Revision Committee, Report of, 76

Convention, greetings to, by Thomas A. Edison, 69

Conventions of the N. E. L. A., 1734

Convention Sessions
  First, 1
  Second, 27
  Third, 54
  Fourth, 73

Corrosion, power plant, bibliography on, 1009

Cost
  principal items of, in public utility regulation, 86

Courses, educational
  bookkeeping and accounting, 210
  electric utility accounting, 212
  electrical metermen's, 216
  lighting sales, 220
  merchandise sales, 220
  power sales, 220
  practical electricity, 214

Current, electric, state laws relating to theft of, 747

Current transformers, 813

Customer Ownership Committee Serial Report, 1506
  Appendix A, Murphy v. Wyandotte County Gas Co., 1524
  bibliography, 1515
  data on customer ownership, 1508
  ten cardinal rules of customer ownership, 1510

Customer Records Committee
  Development of Customers' Accounting Machines, 276
  "The Customer's Side of the Meter," by A. W. Robertson, 23

D

Davidson Prizes, 54

Developing Electric Service for the Farm, as Exemplified by the Organization and Methods of Alabama Power Company, 241
  Agriculture of Alabama, 241
  rural electric development in Alabama, 243
  rural lines and systems, 254

Developing Electric Service for the Farm as Exemplified by the Organization and Methods of Wisconsin Power & Light Company, 225
  essentials for development of rural electric service, 228

Development of Customers' Accounting Machines, 276

D.C. Substation Design Practice, 541
  automatic Edison substations, 542
  automatic railway substations, 584
  non-automatic Edison substations, 550
  non-automatic railway substations, 604

Demand registers, 807

Diesel Engine Power Costs, 308
  bibliography, 314

Distillation Products of Coal, 1177
  bibliography, 1188
  contributed statements, 1179
  foreign developments, 1182
  International Conference on bituminous coal, Pittsburgh, 1183
  low temperature carbonization, 1177
  World Power Conference, London, 1183

Distributing systems, types of, and methods of effecting changeover, 916

Doherty Prize, 54

Domestic Electric Range Committee, Report of, by F. A. Coupal, 123

Domestic Oil Burners, 349
  bibliography, 406
  factors considered in comparing coal, oil, gas and electric heaters, 379
  manufacturers' section, 397
  merchandising, 382
  oil fuel specifications, 406
  oil heat machine, report of test on, 410
  radio interference, 383
  rules for fractional horsepower motors, 427
  sales and installation forms, 415
  service and record in service, 382
  test methods and results, 355

N. E. L. A. *Publications of Interest to Engineers*

OVERHEAD SYSTEMS REFERENCE BOOK

A comprehensive treatise on the art of overhead transmission and distribution of electricity. 592 pages, 8½ x 11¼ inches, 668 illustrations printed on special paper, flexible cover, gold stamping and edges. Price $7.50; to N.E.L.A. members, $5.00.

RELAY HANDBOOK

The only complete work on the art of relay protection. Prepared in cooperation with the A.I.E.E. 1024 pages, 4½ x 6¾ inches, 749 illustrations. Printed on Bible paper, flexible cover, gold stamping on edges. Price $6.00; to N.E.L.A. and A.I.E.E. members, $4.00.

HANDBOOK FOR ELECTRICAL METERMEN

A complete reference work on electricity meters. 1242 pages. 4½ x 6¾ inches, 856 illustrations. Price $6.00; to N.E.L.A. members, $4.00.

ACCIDENT PREVENTION COURSE FOR LINEMEN

A brief, illustrated text for use in linemen's schools. 100 pages, 4 x 6 inches, 11 illustrations. Leatherette cover. Price 25 cents; to N.E.L.A. members, 16 cents.

RESUSCITATION IN GAS POISONING, ELECTRICAL SHOCK AND DROWNING

Publication No. 289-70. Booklet published jointly with American Gas Association. 20 pages, 3¼ x 6 inches, 3 illustrations. Single copies 10 cents, with substantial discounts for quantity purchase.

THE ELECTRIC LIGHT AND POWER INDUSTRY IN THE UNITED STATES (N. E. L. A. HANDBOOK)

Designed to assist men and women in the electric light and power industry in preparing themselves to tell the public the story of the business. Contains detailed statistical data. Compiled by Public Speaking Committee. 138 pages, 8 x 11 inches, loose leaf, leather bound, $2.50 per copy. For a more general distribution and as an aid in disseminating facts and statistics of the industry, this publication also is available in bound form, with paper cover, $1.00 per copy.

STATISTICAL SECTION OF N. E. L. A. HANDBOOK

Revised to January 1, 1929, 32 pages, 8 x 11 inches, paper cover.

COMMITTEE REPORTS

Printed reports of N.E.L.A. National Committees for the administrative year 1928-1929 and previous years are available.

N. E. L. A. PROCEEDINGS

Published annually since 1886. Contains the reports of all committees of the Association for the year covered. Copies for recent years may be obtained at $15.00 each; to N.E.L.A. members, $10.00.

A complete list of current N.E.L.A. publications will be sent on request.
